INSERT ... SELECT /*+ ... */ ...
```
Optimizer Hints

- In hintable statements prefaced by `EXPLAIN`. For example:

  ```sql
  EXPLAIN SELECT /*+ ... */ ...
  EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
  ```

  The implication is that you can use `EXPLAIN` to see how optimizer hints affect execution plans. Use `SHOW WARNINGS` immediately after `EXPLAIN` to see how hints are used. The extended `EXPLAIN` output displayed by a following `SHOW WARNINGS` indicates which hints were used. Ignored hints are not displayed.

  A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

  ```sql
  SELECT /*+ BNL(t1) BKA(t2) */ ...
  ```

  But this is invalid:

  ```sql
  SELECT /*+ BNL(t1) */ /* BKA(t2) */ ...
  ```

  When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

  - **Duplicate hints**: For a hint such as `/*+ MRR(idx1) MRR(idx1) */`, MySQL uses the first hint and issues a warning about the duplicate hint.

  - **Conflicting hints**: For a hint such as `/*+ MRR(idx1) NO_MRR(idx1) */`, MySQL uses the first hint and issues a warning about the second conflicting hint.

  Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see Section 9.2, “Schema Object Names”).

  Hint names, query block names, and strategy names are not case sensitive. References to table and index names follow the usual identifier case sensitivity rules (see Section 9.2.2, “Identifier Case Sensitivity”).

### Join-Order Optimizer Hints

Join-order hints affect the order in which the optimizer joins tables.

**Syntax of the `JOIN_FIXED_ORDER` hint:**

```sql
hint_name([@query_block_name])
```

**Syntax of other join-order hints:**

```sql
hint_name([@query_block_name] tbl_name [, tbl_name] ...)
hint_name(tbl_name[@query_block_name] [, tbl_name[@query_block_name]] ...)```

The syntax refers to these terms:

- **`hint_name`**: These hint names are permitted:

  - **`JOIN_FIXED_ORDER`**: Force the optimizer to join tables using the order in which they appear in the `FROM` clause. This is the same as specifying `SELECT STRAIGHT_JOIN`.
• **JOIN_ORDER**: Instruct the optimizer to join tables using the specified table order. The hint applies to the named tables. The optimizer may place tables that are not named anywhere in the join order, including between specified tables.

• **JOIN_PREFIX**: Instruct the optimizer to join tables using the specified table order for the first tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables after the named tables.

• **JOIN_SUFFIX**: Instruct the optimizer to join tables using the specified table order for the last tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables before the named tables.

• **tbl_name**: The name of a table used in the statement. A hint that names tables applies to all tables that it names. The **JOIN_FIXED_ORDER** hint names no tables and applies to all tables in the **FROM** clause of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

• **query_block_name**: The query block to which the hint applies. If the hint includes no leading @query_block_name, the hint applies to the query block in which it occurs. For **tbl_name@query_block_name** syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Example:

```sql
SELECT /*+ JOIN_PREFIX(t2, t5@subq2, t4@subq1)
JOIN_ORDER(t4@subq1, t3)
JOIN_SUFFIX(t1) */
COUNT(*) FROM t1 JOIN t2 JOIN t3
WHERE t1.f1 IN (SELECT /*+ QB_NAME(subq1) */ f1 FROM t4)
AND t2.f1 IN (SELECT /*+ QB_NAME(subq2) */ f1 FROM t5);
```

Hints control the behavior of semi-join tables that are merged to the outer query block. If subqueries subq1 and subq2 are converted to semi-joins, tables t4@subq1 and t5@subq2 are merged to the outer query block. In this case, the hint specified in the outer query block controls the behavior of t4@subq1, t5@subq2 tables.

The optimizer resolves join-order hints according to these principles:

• Multiple hint instances

  Only one **JOIN_PREFIX** and **JOIN_SUFFIX** hint of each type are applied. Any later hints of the same type are ignored with a warning. **JOIN_ORDER** can be specified several times.

Examples:

```sql
/**+ JOIN_PREFIX(t1) JOIN_PREFIX(t2) */
```

The second **JOIN_PREFIX** hint is ignored with a warning.

```sql
/**+ JOIN_PREFIX(t1) JOIN_SUFFIX(t2) */
```

Both hints are applicable. No warning occurs.
Optimizer Hints

Both hints are applicable. No warning occurs.

• Conflicting hints
In some cases hints can conflict, such as when `JOIN_ORDER` and `JOIN_PREFIX` have table orders that are impossible to apply at the same time:

```
SELECT /*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */ ... FROM t1, t2;
```

In this case, the first specified hint is applied and subsequent conflicting hints are ignored with no warning. A valid hint that is impossible to apply is silently ignored with no warning.

• Ignored hints
A hint is ignored if a table specified in the hint has a circular dependency.

Example:

```
/*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */
```

The `JOIN_ORDER` hint sets table `t2` dependent on `t1`. The `JOIN_PREFIX` hint is ignored because table `t1` cannot be dependent on `t2`. Ignored hints are not displayed in extended `EXPLAIN` output.

• Interaction with `const` tables
The MySQL optimizer places `const` tables first in the join order, and the position of a `const` table cannot be affected by hints. References to `const` tables in join-order hints are ignored, although the hint is still applicable. For example, these are equivalent:

```
JOIN_ORDER(t1, const_tbl, t2)
JOIN_ORDER(t1, t2)
```

Accepted hints shown in extended `EXPLAIN` output include `const` tables as they were specified.

• Interaction with types of join operations
MySQL supports several type of joins: `LEFT`, `RIGHT`, `INNER`, `CROSS`, `STRAIGHT_JOIN`. A hint that conflicts with the specified type of join is ignored with no warning.

Example:

```
SELECT /*+ JOIN_PREFIX(t1, t2) */ FROM t2 LEFT JOIN t1;
```

Here a conflict occurs between the requested join order in the hint and the order required by the `LEFT JOIN`. The hint is ignored with no warning.

Table-Level Optimizer Hints

Table-level hints affect:

• Use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see Section 8.2.1.11, "Block Nested-Loop and Batched Key Access Joins").
• Whether derived tables, view references, or common table expressions should be merged into the outer query block, or materialized using an internal temporary table.

These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])
hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

The syntax refers to these terms:

• **hint_name**: These hint names are permitted:
  - **BKA, NO_BKA**: Enable or disable BKA for the specified tables.
  - **BNL, NO_BNL**: Enable or disable BNL for the specified tables.
  - **MERGE, NO_MERGE**: Enable merging for the specified tables, view references or common table expressions; or disable merging and use materialization instead.

  **Note**
  To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

• **tbl_name**: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

  If a table has an alias, hints must refer to the alias, not the table name.

  Table names in hints cannot be qualified with schema names.

• **query_block_name**: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block.

  To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```
SELECT /*+ NO_BKA(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BKA(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```
SELECT /*+ BNL(t2) */ * FROM t1, t2;
```

If the optimizer chooses to process `t1` first, it applies a Block Nested-Loop join to `t2` by buffering the rows from `t1` before starting to read from `t2`. If the optimizer instead chooses to process `t2` first, the hint has no effect because `t2` is a sender table.

For the **MERGE** and **NO_MERGE** hints, these precedence rules apply:

• A hint takes precedence over any optimizer heuristic that is not a technical constraint. (If providing a hint as a suggestion has no effect, the optimizer has a reason for ignoring it.)
Optimizer Hints

- A hint takes precedence over the derived_merge flag of the optimizer_switch system variable.
- For view references, an ALGORITHM=(MERGE|TEMPTABLE) clause in the view definition takes precedence over a hint specified in the query referencing the view.

Index-Level Optimizer Hints

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), Index Merge, and range optimizations (see Section 8.2.1, “Optimizing SELECT Statements”).

Syntax of index-level hints:

```
hint_name[@query_block_name] tbl_name [index_name [, index_name] ...]
hint_name(tbl_name@query_block_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - **INDEX_MERGE, NO_INDEX_MERGE**: Enable or disable the Index Merge access method for the specified table or indexes. For information about this access method, see Section 8.2.1.3, “Index Merge Optimization“. These hints apply to all three Index Merge algorithms.
    
    The INDEX_MERGE hint forces the optimizer to use Index Merge for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible index combinations and selects the least expensive one. The hint may be ignored if the index combination is inapplicable to the given statement.
    
    The NO_INDEX_MERGE hint disables Index Merge combinations that involve any of the specified indexes. If the hint specifies no indexes, Index Merge is not permitted for the table.
  
  - **MRR, NO_MRR**: Enable or disable MRR for the specified table or indexes. MRR hints apply only to InnoDB and MyISAM tables. For information about this access method, see Section 8.2.1.10, “Multi-Range Read Optimization”.
  
  - **NO_ICP**: Disable ICP for the specified table or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it. For information about this access method, see Section 8.2.1.5, “Index Condition Pushdown Optimization”.
  
  - **NO_RANGE_OPTIMIZATION**: Disable index range access for the specified table or indexes. This hint also disables Index Merge and Loose Index Scan for the table or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.
    
    This hint may be useful when the number of ranges may be high and range optimization would require many resources.
  
  - **SKIP_SCAN, NO_SKIP_SCAN**: Enable or disable the Skip Scan access method for the specified table or indexes. For information about this access method, see Skip Scan Range Access Method. These hints are available as of MySQL 8.0.13.
    
    The SKIP_SCAN hint forces the optimizer to use Skip Scan for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible indexes and selects the least expensive one. The hint may be ignored if the index is inapplicable to the given statement.
    
    The NO_SKIP_SCAN hint disables Skip Scan for the specified indexes. If the hint specifies no indexes, Skip Scan is not permitted for the table.
Optimizer Hints

• **tbl_name**: The table to which the hint applies.

• **index_name**: The name of an index in the named table. The hint applies to all indexes that it names. If
  the hint names no indexes, it applies to all indexes in the table.

  To refer to a primary key, use the name **PRIMARY**. To see the index names for a table, use **SHOW
  INDEX**.

• **query_block_name**: The query block to which the hint applies. If the hint includes no
  leading `@query_block_name` syntax, the hint applies to the query block in which it occurs. For
  `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block.
  To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```
SELECT /*+ INDEX_MERGE(t1 f3, PRIMARY) */ f2 FROM t1
  WHERE f1 = 'o' AND f2 = f3 AND f3 <= 4;
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
INSERT INTO t3(f1, f2, f3)
  (SELECT /*+ NO_ICP(t2) */ t2.f1, t2.f2, t2.f3 FROM t1,t2
      WHERE t1.f1=t2.f1 AND t2.f2 BETWEEN t1.f1
        AND t1.f2 AND t2.f2 + 1 >= t1.f1 + 1);
SELECT /*+ SKIP_SCAN(t1 PRIMARY) */ f1, f2
  FROM t1 WHERE f2 > 40;
```

The following examples use the Index Merge hints, but other index-level hints follow the same principles
regarding hint ignoring and precedence of optimizer hints in relation to the **optimizer_switch** system
variable or index hints.

Assume that table **t1** has columns **a**, **b**, **c**, and **d**; and that indexes named **i_a**, **i_b**, and **i_c** exist on **a**, **b**, and **c**, respectively:

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
  WHERE a = 1 AND b = 2 AND c = 3 AND d = 4;
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
  WHERE b = 1 AND c = 2 AND d = 3;
/*+ INDEX_MERGE(t1 i_a, i_b) NO_INDEX_MERGE(t1 i_b) */
NO_INDEX_MERGE is ignored because there is a preceding hint for the same table.
/*+ NO_INDEX_MERGE(t1 i_a, i_b) INDEX_MERGE(t1 i_b) */
INDEX_MERGE is ignored because there is a preceding hint for the same table.
```

For the **INDEX_MERGE** and **NO_INDEX_MERGE** optimizer hints, these precedence rules apply:

• If an optimizer hint is specified and is applicable, it takes precedence over the Index Merge-related flags
  of the **optimizer_switch** system variable.
Optimizer Hints

SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b, i_c) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;

The hint takes precedence over optimizer_switch. Index Merge is used for (i_b, i_c) in this case.

SET optimizer_switch='index_merge_intersection=on';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;

The hint specifies only one index, so it is inapplicable, and the optimizer_switch flag (on) applies. Index Merge is used if the optimizer assesses it to be cost efficient.

SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;

The hint specifies only one index, so it is inapplicable, and the optimizer_switch flag (off) applies. Index Merge is not used.

- The USE INDEX, FORCE INDEX, and IGNORE INDEX index hints have higher priority than the INDEX_MERGE and NO_INDEX_MERGE optimizer hints.

/**+ INDEX_MERGE(t1 i_a, i_b, i_c) */ ... IGNORE INDEX i_a

IGNORE INDEX takes precedence over INDEX_MERGE, so index i_a is excluded from the possible ranges for Index Merge.

/**+ NO_INDEX_MERGE(t1 i_a, i_b) */ ... FORCE INDEX i_a, i_b

Index Merge is disallowed for i_a, i_b because of FORCE INDEX, but the optimizer is forced to use either i_a or i_b for range or ref access. There are no conflicts; both hints are applicable.

- If an IGNORE INDEX hint names multiple indexes, those indexes are unavailable for Index Merge.

- The FORCE INDEX and USE INDEX hints make only the named indexes to be available for Index Merge.

SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c) */ a FROM t1
FORCE INDEX (i_a, i_b) WHERE c = 'h' AND a = 2 AND b = 'b';

The Index Merge intersection access algorithm is used for (i_a, i_b). The same is true if FORCE INDEX is changed to USE INDEX.

Subquery Optimizer Hints

Subquery hints affect whether to use semi-join transformations and which semi-join strategies to permit, and, when semi-joins are not used, whether to use subquery materialization or IN-to-EXISTS transformations. For more information about these optimizations, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

Syntax of hints that affect semi-join strategies:

```
hint_name([@query_block_name] [strategy [, strategy] ...])
```
The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - **SEMIJOIN, NO_SEMIJOIN**: Enable or disable the named semi-join strategies.

- **strategy**: A semi-join strategy to be enabled or disabled. These strategy names are permitted: DUPSWEEDOUT, FIRSTMATCH, LOOSESCAN, MATERIALIZATION.

For **SEMIJOIN** hints, if no strategies are named, semi-join is used if possible based on the strategies enabled according to the `optimizer_switch` system variable. If strategies are named but inapplicable for the statement, DUPSWEEDOUT is used.

For **NO_SEMIJOIN** hints, if no strategies are named, semi-join is not used. If strategies are named that rule out all applicable strategies for the statement, DUPSWEEDOUT is used.

If one subquery is nested within another and both are merged into a semi-join of an outer query, any specification of semi-join strategies for the innermost query are ignored. **SEMIJOIN** and **NO_SEMIJOIN** hints can still be used to enable or disable semi-join transformations for such nested subqueries.

If **DUPSWEEDOUT** is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

**Examples:**

```sql
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOOSESCAN) */ * FROM t2
WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

```sql
SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEDOUT) */ * FROM t2
WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

Syntax of hints that affect whether to use subquery materialization or **IN-to-EXISTS** transformations:

```sql
SUBQUERY([@query_block_name] strategy)
```

The hint name is always **SUBQUERY**.

For **SUBQUERY** hints, these **strategy** values are permitted: INTOEXISTS, MATERIALIZATION.

**Examples:**

```sql
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```

For semi-join and **SUBQUERY** hints, a leading `@query_block_name` specifies the query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.

**Statement Execution Time Optimizer Hints**

The **MAX_EXECUTION_TIME** hint is permitted only for **SELECT** statements. It places a limit $N$ (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:
MAX_EXECUTION_TIME(N)

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM t1 INNER JOIN t2 WHERE ...
```

The `MAX_EXECUTION_TIME(N)` hint sets a statement execution timeout of `N` milliseconds. If this option is absent or `N` is 0, the statement timeout established by the `max_execution_time` system variable applies.

The `MAX_EXECUTION_TIME` hint is applicable as follows:

- For statements with multiple `SELECT` keywords, such as unions or statements with subqueries, `MAX_EXECUTION_TIME` applies to the entire statement and must appear after the first `SELECT`.
- It applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to `SELECT` statements in stored programs and is ignored.

### Variable-Setting Hint Syntax

The `SET_VAR` hint sets the session value of a system variable temporarily (for the duration of a single statement). Examples:

```
SELECT /*+ SET_VAR(sort_buffer_size = 16M) */ name FROM people ORDER BY name;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off') */ 1;
```

Syntax of the `SET_VAR` hint:

```
SET_VAR(var_name = value)
```

- `var_name` names a system variable that has a session value (although not all such variables can be named, as explained later). `value` is the value to assign to the variable; the value must be a scalar.
- `SET_VAR` makes a temporary variable change, as demonstrated by these statements:

```
mysql> SELECT @@unique_checks;
+-----------------+
| @@unique_checks |
+-----------------+
| 1               |
+-----------------+

mysql> SELECT /*+ SET_VAR(unique_checks=OFF) */ @@unique_checks;
+-----------------+
| @@unique_checks |
+-----------------+
| 0               |
+-----------------+

mysql> SELECT @@unique_checks;
+-----------------+
| @@unique_checks |
+-----------------+
| 1               |
+-----------------+
```

With `SET_VAR`, there is no need to save and restore the variable value. This enables you to replace multiple statements by a single statement. Consider this sequence of statements:
The sequence can be replaced by this single statement:

```
SELECT /*+ SET_VAR(var_name = value) */ ...
```

Standalone `SET` statements permit any of these syntaxes for naming session variables:

```
SET SESSION var_name = value;
SET @@SESSION.var_name = value;
SET @@.var_name = value;
```

Because the `SET_VAR` hint applies only to session variables, session scope is implicit, and `SESSION`, `@@SESSION.`, and `@@` are neither needed nor permitted. Including explicit session-indicator syntax results in the `SET_VAR` hint being ignored with a warning.

Not all session variables are permitted for use with `SET_VAR`. Individual system variable descriptions indicate whether each variable is hintable; see Section 5.1.8, "Server System Variables". You can also check a system variable at runtime by attempting to use it with `SET_VAR`. If the variable is not hintable, a warning occurs:

```
mysql> SELECT /*+ SET_VAR(collation_server = 'utf8') */ 1;
+---+
| 1 |
+---+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 4537
Message: Variable 'collation_server' cannot be set using SET_VAR hint.
```

`SET_VAR` syntax permits setting only a single variable, but multiple hints can be given to set multiple variables:

```
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off')
         SET_VAR(max_heap_table_size = 1G) */ 1;
```

If several hints with the same variable name appear in the same statement, the first one is applied and the others are ignored with a warning:

```
SELECT /*+ SET_VAR(max_heap_table_size = 1G)
         SET_VAR(max_heap_table_size = 3G) */ 1;
```

In this case, the second hint is ignored with a warning that it is conflicting.

A `SET_VAR` hint is ignored with a warning if no system variable has the specified name or the variable value is incorrect:

```
SELECT /*+ SET_VAR(max_size = 1G) */ 1;
```
For the first statement, there is no \texttt{max\_size} variable. For the second statement, \texttt{mrr\_cost\_flag} takes values of \texttt{on} or \texttt{off}, so attempting to set it to \texttt{yes} is incorrect. In each case, the hint is ignored with a warning.

The \texttt{SET\_VAR} hint is permitted only at the statement level. If used in a subquery, the hint is ignored with a warning.

Slave servers ignore \texttt{SET\_VAR} hints in replicated statements to avoid the potential for security issues.

\section*{Resource Group Hint Syntax}

The \texttt{RESOURCE\_GROUP} optimizer hint is used for resource group management (see Section 8.12.5, “Resource Groups”). This hint assigns the thread that executes a statement to the named resource group temporarily (for the duration of the statement). It requires the \texttt{RESOURCE\_GROUP\_ADMIN} or \texttt{RESOURCE\_GROUP\_USER} privilege.

Examples:

\begin{verbatim}
SELECT /*+ RESOURCE\_GROUP(USR\_default) */ name FROM people ORDER BY name;
INSERT /*+ RESOURCE\_GROUP(Batch) */ INTO t2 VALUES(2);
\end{verbatim}

Syntax of the \texttt{RESOURCE\_GROUP} hint:

\texttt{RESOURCE\_GROUP(group\_name)}

\texttt{group\_name} indicates the resource group to which the thread should be assigned for the duration of statement execution. If the group is nonexistent, a warning occurs and the hint is ignored.

The \texttt{RESOURCE\_GROUP} hint must appear after the initial statement keyword (\texttt{SELECT}, \texttt{INSERT}, \texttt{REPLACE}, \texttt{UPDATE}, or \texttt{DELETE}).

An alternative to \texttt{RESOURCE\_GROUP} is the \texttt{SET RESOURCE GROUP} statement, which nontemporarily assigns threads to a resource group. See Section 13.7.2.4, “SET RESOURCE GROUP Syntax”.

\section*{Optimizer Hints for Naming Query Blocks}

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the \texttt{QB\_NAME} hint, which assigns a name to the query block in which it occurs:

\texttt{QB\_NAME(name)}

\texttt{QB\_NAME} hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:

\begin{verbatim}
SELECT ...
  FROM (SELECT ...
        FROM (SELECT ...
          FROM (SELECT ...
            FROM ...)) ...
      FROM (SELECT ... FROM ...)) ...
\end{verbatim}

\texttt{QB\_NAME} hints assign names to query blocks in the statement:
Switchable Optimizations

The optimizer_switch system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of on or off to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @optimizer_switch\G
                   ^
0 rows
```

To change the value of optimizer_switch, assign a value consisting of a comma-separated list of one or more commands:
Switchable Optimizations

SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';

Each *command* value should have one of the forms shown in the following table.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Reset every optimization to its default value</td>
</tr>
<tr>
<td>opt_name=default</td>
<td>Set the named optimization to its default value</td>
</tr>
<tr>
<td>opt_name=off</td>
<td>Disable the named optimization</td>
</tr>
<tr>
<td>opt_name=on</td>
<td>Enable the named optimization</td>
</tr>
</tbody>
</table>

The order of the commands in the value does not matter, although the *default* command is executed first if present. Setting an *opt_name* flag to *default* sets it to whichever of *on* or *off* is its default value. Specifying any given *opt_name* more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of *optimizer_switch* unchanged.

The following list describes the permissible *opt_name* flag names, grouped by optimization strategy:

- **Batched Key Access Flags**
  - *batched_key_access* (default *off*)
    - Controls use of BKA join algorithm.
    - For *batched_key_access* to have any effect when set to *on*, the *mrr* flag must also be *on*. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for *mrr_cost_based* to be *off* for BKA to be used.
    - For more information, see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”.

- **Block Nested-Loop Flags**
  - *block_nested_loop* (default *on*)
    - Controls use of BNL join algorithm.
    - For more information, see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”.

- **Condition Filtering Flags**
  - *condition_fanout_filter* (default *on*)
    - Controls use of condition filtering.
    - For more information, see Section 8.2.1.12, “Condition Filtering”.

- **Derived Table Merging Flags**
  - *derived_merge* (default *on*)
    - Controls merging of derived tables and views into outer query block.
    - The *derived_merge* flag controls whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block, assuming that no other rule
prevents merging; for example, an \texttt{ALGORITHM} directive for a view takes precedence over the \texttt{derived_merge} setting. By default, the flag is \texttt{on} to enable merging.

For more information, see Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

• Engine Condition Pushdown Flags
  
  \texttt{engine_condition_pushdown} (default \texttt{on})

  Controls engine condition pushdown.

  For more information, see Section 8.2.1.4, “Engine Condition Pushdown Optimization”.

• Index Condition Pushdown Flags
  
  \texttt{index_condition_pushdown} (default \texttt{on})

  Controls index condition pushdown.

  For more information, see Section 8.2.1.5, “Index Condition Pushdown Optimization”.

• Index Extensions Flags
  
  \texttt{use_index_extensions} (default \texttt{on})

  Controls use of index extensions.

  For more information, see Section 8.3.10, “Use of Index Extensions”.

• Index Merge Flags
  
  \texttt{index_merge} (default \texttt{on})

  Controls all Index Merge optimizations.

  \texttt{index_merge_intersection} (default \texttt{on})

  Controls the Index Merge Intersection Access optimization.

  \texttt{index_merge_sort_union} (default \texttt{on})

  Controls the Index Merge Sort-Union Access optimization.

  \texttt{index_merge_union} (default \texttt{on})

  Controls the Index Merge Union Access optimization.

  For more information, see Section 8.2.1.3, “Index Merge Optimization”.

• Index Visibility Flags
  
  \texttt{use_invisible_indexes} (default \texttt{off})

  Controls use of invisible indexes.

  For more information, see Section 8.3.12, “Invisible Indexes”.

• Multi-Range Read Flags
Switchable Optimizations

- **mrr** *(default on)*  
  Controls the Multi-Range Read strategy.

- **mrr_cost_based** *(default on)*  
  Controls use of cost-based MRR if mrr=on.

For more information, see Section 8.2.1.10, “Multi-Range Read Optimization”.

- **Skip Scan Flags**
  - **skip_scan** *(default on)*  
    Controls use of Skip Scan access method.

  For more information, see Skip Scan Range Access Method.

- **Semi-Join Flags**
  - **semijoin** *(default on)*  
    Controls all semi-join strategies.

  - **duplicateweedout** *(default on)*  
    Controls the semi-join Duplicate Weedout strategy.

  - **firstmatch** *(default on)*  
    Controls the semi-join FirstMatch strategy.

  - **loosescan** *(default on)*  
    Controls the semi-join LooseScan strategy (not to be confused with Loose Index Scan for GROUP BY).

The semijoin, firstmatch, loosescan, and duplicateweedout flags enable control over semi-join strategies. The semijoin flag controls whether semi-joins are used. If it is set to on, the firstmatch and loosescan flags enable finer control over the permitted semi-join strategies.

If the duplicateweedout semi-join strategy is disabled, it is not used unless all other applicable strategies are also disabled.

If semijoin and materialization are both on, semi-joins also use materialization where applicable. These flags are on by default.

For more information, see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions with Semi-Join Transformations”.

- **Subquery Materialization Flags**
  - **materialization** *(default on)*  
    Controls materialization (including semi-join materialization).

  - **subquery_materialization_cost_based** *(default on)*  
    Use cost-based materialization choice.
Index Hints

The `materialization` flag controls whether subquery materialization is used. If `semijoin` and `materialization` are both on, semi-joins also use materialization where applicable. These flags are on by default.

The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and IN-to-EXISTS subquery transformation. If the flag is on (the default), the optimizer performs a cost-based choice between subquery materialization and IN-to-EXISTS subquery transformation if either method could be used. If the flag is off, the optimizer chooses subquery materialization over IN-to-EXISTS subquery transformation.

For more information, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”.

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch
+--------------------------+
| @@optimizer_switch       |
| index_merge=on,index_merge_union=on, |
| index_merge_sort_union=on,       |
| index_merge_intersection=on,     |
| engine_condition_pushdown=on,    |
| index_condition_pushdown=on,     |
| mrr=on,mrr_cost_based=on,        |
| block_nested_loop=on,batched_key_access=off, |
| materialization=on,semijoin=on,loosescan=on, |
| firstmatch=on,                |
| subquery_materialization_cost_based=on, |
| use_index_extensions=on,       |
| condition_fanout_filter=on     |
+--------------------------+
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';
mysql> SELECT @@optimizer_switch
+--------------------------+
| @@optimizer_switch       |
| index_merge=on,index_merge_union=off, |
| index_merge_sort_union=off,       |
| index_merge_intersection=on,     |
| engine_condition_pushdown=on,    |
| index_condition_pushdown=on,     |
| mrr=on,mrr_cost_based=on,        |
| block_nested_loop=on,batched_key_access=off, |
| materialization=on,semijoin=on,loosescan=on, |
| firstmatch=on,                |
| subquery_materialization_cost_based=on, |
| use_index_extensions=on,       |
| condition_fanout_filter=on     |
+--------------------------+
```

8.9.4 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in Section 8.9.2, “Optimizer Hints”. Index and optimizer hints may be used separately or together.
Index hints apply only to `SELECT` statements. (They are accepted by the parser for `UPDATE` statements but are ignored and have no effect.)

Index hints are specified following a table name. (For the general syntax for specifying tables in a `SELECT` statement, see Section 13.2.10.2, “JOIN Syntax”.) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]
```

```
index_hint_list:
  index_hint [index_hint] ...

index_hint:
  USE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
  | {IGNORE|FORCE} {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...
```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be very expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Each hint requires index names, not column names. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA.STATISTICS` table.

An `index_name` value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;
SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit `index_list` for `USE INDEX`, which means “use no indexes.” Omitting `index_list` for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.

- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`.

- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```
Index Hints

It is not an error to name the same index in several hints (even within the same hint):

```sql
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```sql
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no `FOR` clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

```sql
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```sql
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

In MySQL 5.0, hint scope with no `FOR` clause was to apply only to row retrieval. To cause the server to use this older behavior when no `FOR` clause is present, enable the `old` system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (`USE`, `FORCE`, `IGNORE`) and by scope (`FOR JOIN`, `FOR ORDER BY`, `FOR GROUP BY`). For example:

```sql
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```sql
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. `{USE|FORCE} INDEX` is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. `IGNORE INDEX` is applied over the result of the previous step. For example, the following two queries are equivalent:

```sql
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1);
```

For `FULLTEXT` searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, `IGNORE INDEX(i1)` is ignored with no warning and the index is still used.

- For boolean mode searches, index hints with `FOR ORDER BY` or `FOR GROUP BY` are silently ignored. Index hints with `FOR JOIN` or no `FOR` modifier are honored. In contrast to how hints apply for non-`FULLTEXT` searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-`FULLTEXT` index.
For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;
```

```
SELECT * FROM t
  USE INDEX (index1)
  WHERE ... IN BOOLEAN MODE ... ;
```

### 8.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

The optimizer also has a database of cost estimates to use during execution plan construction. These estimates are stored in the `server_cost` and `engine_cost` tables in the `mysql` system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

- **Cost Model General Operation**
- **The Cost Model Database**
- **Making Changes to the Cost Model Database**

#### Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-`NULL` cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any `NULL` estimate indicates to the optimizer to use the compiled-in default.

- At runtime, the server may reread the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.

- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry’s cost to `NULL`. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.

- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server rereads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.

- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replication slaves.

#### The Cost Model Database

The optimizer cost model database consists of two tables in the `mysql` system database that contain cost estimate information for operations that occur during query execution:

- **server_cost**: Optimizer cost estimates for general server operations
The Optimizer Cost Model

- **engine_cost**: Optimizer cost estimates for operations specific to particular storage engines

The **server_cost** table contains these columns:

- **cost_name**
  The name of a cost estimate used in the cost model. The name is not case-sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

- **cost_value**
  The cost estimate value. If the value is non-`NULL`, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

  To override a default cost estimate (for an entry that specifies `NULL`), set the cost to a non-`NULL` value. To revert to the default, set the value to `NULL`. Then execute `FLUSH OPTIMIZER_COSTS` to tell the server to reread the cost tables.

- **last_update**
  The time of the last row update.

- **comment**
  A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

- **default_value**
  The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is `NULL`.

The primary key for the **server_cost** table is the **cost_name** column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these **cost_name** values for the **server_cost** table:

- **disk_temptable_create_cost, disk_temptable_row_cost**
  The cost estimates for internally created temporary tables stored in a disk-based storage engine (either InnoDB or MyISAM). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, "Internal Temporary Table Use in MySQL".

  The larger default values for these disk parameters compared to the default values for the corresponding memory parameters (**memory_temptable_create_cost, memory_temptable_row_cost**) reflects the greater cost of processing disk-based tables.

- **key_compare_cost**
  The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a **filesort** becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

- **memory_temptable_create_cost, memory_temptable_row_cost**
The Optimizer Cost Model

The cost estimates for internally created temporary tables stored in the MEMORY storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters (disk_temptable_create_cost, disk_temptable_row_cost) reflects the lesser cost of processing memory-based tables.

- **row_evaluate_cost**

  The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The **engine_cost** table contains these columns:

- **engine_name**

  The name of the storage engine to which this cost estimate applies. The name is not case-sensitive. If the value is default, it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- **device_type**

  The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- **cost_name**

  Same as in the **server_cost** table.

- **cost_value**

  Same as in the **server_cost** table.

- **last_update**

  Same as in the **server_cost** table.

- **comment**

  Same as in the **server_cost** table.

- **default_value**

  The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is NULL, with the exception that if the row has the same cost_name value as one of the original rows, the default_value column will have the same value as that row.

The primary key for the **engine_cost** table is a tuple comprising the (cost_name, engine_name, device_type) columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these cost_name values for the **engine_cost** table:
• **io_block_read_cost**

  The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

• **memory_block_read_cost**

  Similar to **io_block_read_cost**, but represents the cost of reading an index or data block from an in-memory database buffer.

  If the **io_block_read_cost** and **memory_block_read_cost** values differ, the execution plan may change between two runs of the same query. Suppose that the cost for memory access is less than the cost for disk access. In that case, at server startup before data has been read into the buffer pool, you may get a different plan than after the query has been run because then the data will be in memory.

### Making Changes to the Cost Model Database

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.

Changes to the **io_block_read_cost** and **memory_block_read_cost** parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting **io_block_read_cost** to a value larger than **memory_block_read_cost** causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for **io_block_read_cost**:

```sql
UPDATE mysql.engine_cost
SET cost_value = 2.0
WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of **io_block_read_cost** only for the InnoDB storage engine:

```sql
INSERT INTO mysql.engine_cost
VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

### 8.9.6 Optimizer Statistics

The **column_statistics** data dictionary table stores histogram statistics about column values, for use by the optimizer in constructing query execution plans. To perform histogram management, use the **ANALYZE TABLE** statement; see Section 13.7.3.1, “**ANALYZE TABLE Syntax**”.

The **column_statistics** table has these characteristics:

- The table contains statistics for columns of all data types except geometry types (spatial data) and **JSON**.
- The table is persistent so that column statistics need not be created each time the server starts.
- The server performs updates to the table; users do not.
The `column_statistics` table is not directly accessible by users because it is part of the data dictionary. Histogram information is available using `INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary table. `COLUMN_STATISTICS` has these columns:

- **SCHEMA_NAME, TABLE_NAME, COLUMN_NAME**: The names of the schema, table, and column for which the statistics apply.
- **HISTOGRAM**: A JSON value describing the column statistics, stored as a histogram.

Column histograms contain buckets for parts of the range of values stored in the column. Histograms are JSON objects to permit flexibility in the representation of column statistics. Here is a sample histogram object:

```
{
    "buckets": [ [
        1,
        0.3333333333333333
    ], [
        2,
        0.6666666666666666
    ], [
        3,
        1
    ]
],
"null-values": 0,
"last-updated": "2017-03-24 13:32:40.000000",
"sampling-rate": 1,
"histogram-type": "singleton",
"number-of-buckets-specified": 128,
"data-type": "int",
"collation-id": 8
}
```

Histogram objects have these keys:

- **buckets**: The histogram buckets. Bucket structure depends on the histogram type.

  For **singleton** histograms, buckets contain two values:

  - Value 1: The value for the bucket. The type depends on the column data type.
  - Value 2: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket value.

  For **equi-height** histograms, buckets contain four values:

  - Values 1, 2: The lower and upper inclusive values for the bucket. The type depends on the column data type.
  - Value 3: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket upper value.
  - Value 4: The number of distinct values in the range from the bucket lower value to its upper value.

- **null-values**: A number between 0.0 and 1.0 indicating the fraction of column values that are SQL NULL values. If 0, the column contains no NULL values.
Optimizer Statistics

- **last-updated**: When the histogram was generated, as a UTC value in `YYYY-MM-DD HH:MM:SS.hmmss` format.

- **sampling-rate**: A number between 0.0 and 1.0 indicating the fraction of data that was sampled to create the histogram. A value of 1 means that all of the data was read (no sampling).

- **histogram-type**: The histogram type:
  - **singleton**: One bucket represents one single value in the column. This histogram type is created when the number of distinct values in the column is less than or equal to the number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.
  - **equi-height**: One bucket represents a range of values. This histogram type is created when the number of distinct values in the column is greater than the number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.

- **number-of-buckets-specified**: The number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.

- **data-type**: The type of data this histogram contains. This is needed when reading and parsing histograms from persistent storage into memory. The value is one of `int`, `uint` (unsigned integer), `double`, `decimal`, `datetime`, or `string` (includes character and binary strings).

- **collation-id**: The collation ID for the histogram data. It is mostly meaningful when the `data-type` value is `string`. Values correspond to ID column values in the `INFORMATION_SCHEMA.COLLATIONS` table.

To extract particular values from the histogram objects, you can use JSON operations. For example:

```sql
mysql> SELECT TABLE_NAME, COLUMN_NAME, HISTOGRAM->>'$.data-type' AS 'data-type', JSON_LENGTH(HISTOGRAM->>'$.buckets') AS 'bucket-count'
FROM INFORMATION_SCHEMA.COLUMN_STATISTICS;
+-----------------+-------------+-----------+--------------+
| TABLE_NAME      | COLUMN_NAME | data-type | bucket-count |
|-----------------+-------------+-----------+--------------|
| country         | Population  | int       | 226          |
| city            | Population  | int       | 1024         |
| countrylanguage| Language    | string    | 457          |
+-----------------+-------------+-----------+--------------+
```

The optimizer uses histogram statistics, if applicable, for columns of any data type for which statistics are collected. The optimizer applies histogram statistics to determine row estimates based on the selectivity (filtering effect) of column value comparisons against constant values. Predicates of these forms qualify for histogram use:

```sql
col_name = constant
col_name <> constant
col_name != constant
col_name > constant
col_name < constant
col_name >= constant
col_name <= constant
col_name IS NULL
col_name IS NOT NULL
col_name BETWEEN constant AND constant
col_name NOT BETWEEN constant AND constant
col_name IN (constant[, constant] ...)
col_name NOT IN {constant[, constant] ...)
```
For example, these statements contain predicates that qualify for histogram use:

```
SELECT * FROM orders WHERE amount BETWEEN 100.0 AND 300.0;
SELECT * FROM tbl WHERE col1 = 15 AND col2 > 100;
```

The requirement for comparison against a constant value includes functions that are constant, such as `ABS()` and `FLOOR()`:

```
SELECT * FROM tbl WHERE col1 < ABS(-34);
```

Histogram statistics are useful primarily for nonindexed columns. Adding an index to a column for which histogram statistics are applicable might also help the optimizer make row estimates. The tradeoffs are:

- An index must be updated when table data is modified.
- A histogram is created or updated only on demand, so it adds no overhead when table data is modified. On the other hand, the statistics become progressively more out of date when table modifications occur, until the next time they are updated.

The optimizer prefers range optimizer row estimates to those obtained from histogram statistics. If the optimizer determines that the range optimizer applies, it does not use histogram statistics.

For columns that are indexed, row estimates can be obtained for equality comparisons using index dives (see Section 8.2.1.2, “Range Optimization”). In this case, histogram statistics are not necessarily useful because index dives can yield better estimates.

In some cases, use of histogram statistics may not improve query execution; for example, if the statistics are out of date. To check whether this is the case, use `ANALYZE TABLE` to regenerate the histogram statistics, then run the query again.

Alternatively, to disable histogram statistics, use `ANALYZE TABLE` to drop them. A different method of disabling histogram statistics is to turn off the `condition_fanout_filter` flag of the `optimizer_switch` system variable (although this may disable other optimizations as well):

```
SET optimizer_switch='condition_fanout_filter=off';
```

If histogram statistics are used, the resulting effect is visible using `EXPLAIN`. Consider the following query, where no index is available for column `col1`:

```
SELECT * FROM t1 WHERE col1 < 24;
```

If histogram statistics indicate that 57% of the rows in `t1` satisfy the `col1 < 24` predicate, filtering can occur even in the absence of an index, and `EXPLAIN` shows 57.00 in the `filtered` column.

### 8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

#### 8.10.1 InnoDB Buffer Pool Optimization

InnoDB maintains a storage area called the buffer pool for caching data and indexes in memory. Knowing how the InnoDB buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the InnoDB buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see Section 15.5.1, “Buffer Pool”.
8.10.2 The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the key cache (or key buffer) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.

- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.

- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the key_buffer_size system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the key_buffer_size value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.
Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The *InnoDB* storage engine also uses an LRU algorithm, to manage its buffer pool. See Section 15.5.1, “Buffer Pool”.

### 8.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

### 8.10.2.2 Multiple Key Caches

*Note*

As of MySQL 8.0, the compound-part structured-variable syntax discussed here for referring to multiple *MyISAM* key caches is deprecated.

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given *MyISAM* table. By default, all *MyISAM* table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the *CACHE INDEX* statement (see Section 13.7.7.2, “*CACHE INDEX Syntax*”). For example, the following statement assigns indexes from the tables *t1*, *t2*, and *t3* to the key cache named *hot_cache*:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

```
+---------+--------------------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t3</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

The key cache referred to in a *CACHE INDEX* statement can be created by setting its size with a *SET GLOBAL* parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:
The MyISAM Key Cache

mysql> SET GLOBAL keycache1.key_buffer_size=0;

You cannot destroy the default key cache. Any attempt to do this is ignored:

mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+

Key cache variables are structured system variables that have a name and components. For keycache1.key_buffer_size, keycache1 is the cache variable name and key_buffer_size is the cache component. See Section 5.1.9.5, "Structured System Variables", for a description of the syntax used referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The CACHE INDEX statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an init-file option that names a file containing CACHE INDEX statements to be executed. For example:

\[
\begin{align*}
&\text{key_buffer_size} = 4G \\
&\text{hot_cache.key_buffer_size} = 2G
\end{align*}
\]
The MyISAM Key Cache

cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

8.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the midpoint insertion strategy.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least key_cache_division_limit percent of the key cache blocks. key_cache_division_limit is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing $N$ blocks, the block at the beginning of the hot sublist not accessed within the last $N \times \text{key_cache_age_threshold} / 100$ hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the key_cache_division_limit value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the key_cache_division_limit set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

8.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:
Caching of Prepared Statements and Stored Programs

mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+---------+--------------+----------+----------+

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 8.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of `MyISAM` tables, use the `--myisam-block-size` option at server startup.

### 8.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```sql
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

### 8.10.3 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of re-converting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function).
The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)

- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with `INSERT` or `UPDATE`) do not change metadata, nor do `SELECT` statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```sql
PREPARE s1 FROM 'SELECT * FROM t1';
```

The `SELECT *` expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with `ALTER TABLE`, the prepared statement goes out of date. If the server does not detect this change the next time the client executes `s1`, the prepared statement will return incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as `DECLARE CURSOR` or flow-control statements such as `IF`, `CASE`, and `RETURN`.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a `SELECT *` within the program that accesses the table or view, but not for a `SELECT *` that does not access the table or view.

- When a statement is affected, the server reparses it only partially if possible. Consider this `CASE` statement:

```sql
CASE case_expr
    WHEN when_expr1 ...
    WHEN when_expr2 ...
    WHEN when_expr3 ...
    ...
END CASE
```

If a metadata change affects only `WHEN when_expr3`, that expression is reparsed. `case_expr` and the other `WHEN` expressions are not reparsed.
Reparsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Reparsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.

For prepared statements, the `Com_stmt_reprepare` status variable tracks the number of repreparations.

### 8.11 Optimizing Locking Operations

MySQL manages contention for table contents using **locking**:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 8.11.1, “Internal Locking Methods”.

- External locking occurs when the server and other programs lock **MyISAM** table files to coordinate among themselves which program can access the tables at which time. See Section 8.11.5, “External Locking”.

### 8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see Section 8.11.5, “External Locking”.

- **Row-Level Locking**

- **Table-Level Locking**

- **Choosing the Type of Locking**

#### Row-Level Locking

MySQL uses **row-level locking** for **InnoDB** tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid deadlocks when performing multiple concurrent write operations on a single **InnoDB** table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because **InnoDB** automatically detects deadlock conditions by default and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
Internal Locking Methods

• Fewer changes for rollbacks.
• Possible to lock a single row for a long time.

Table-Level Locking

MySQL uses table-level locking for MyISAM, MEMORY, and MERGE tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid deadlocks by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

• Relatively little memory required (row locking requires memory per row or group of rows locked)
• Fast when used on a large part of the table because only a single lock is involved.
• Fast if you often do GROUP BY operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy SELECT activity for the table. However, if there are many updates for a table, SELECT statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 8.11.2, “Table Locking Issues”.

You can analyze the table lock contention on your system by checking the Table_locks_immediate and Table_locks_waited status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table\%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

The Performance Schema lock tables also provide locking information. See Section 26.12.12, “Performance Schema Lock Tables”.

1529
The MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent INSERT and SELECT statements for a MyISAM table without locks. That is, you can insert rows into a MyISAM table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the concurrent_insert system variable. See Section 8.11.3, “Concurrent Inserts”.

If you acquire a table lock explicitly with LOCK TABLES, you can request a READ LOCAL lock rather than a READ lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many INSERT and SELECT operations on a table t1 when concurrent inserts are not possible, you can insert rows into a temporary table temp_t1 and update the real table with the rows from the temporary table:

```sql
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

### Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

  ```sql
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```

- SELECT combined with concurrent INSERT statements, and very few UPDATE or DELETE statements.
- Many scans or GROUP BY operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”

- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.

- Instead of using row-level locks, you can employ application-level locks, such as those provided by GET_LOCK() and RELEASE_LOCK() in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 12.14, “Locking Functions”.

### 8.11.2 Table Locking Issues
InnoDB tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the LOCK TABLES statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the InnoDB storage engine is the default in MySQL.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except InnoDB. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- Performance Considerations Favoring InnoDB
- Workarounds for Locking Performance Issues

**Performance Considerations Favoring InnoDB**

When choosing whether to create a table using InnoDB or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

- A SELECT statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue SELECT statements will queue up behind it, reducing concurrency even for read-only sessions.

**Workarounds for Locking Performance Issues**

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the InnoDB storage engine, either using CREATE TABLE ... ENGINE=INNODB during setup, or using ALTER TABLE ... ENGINE=INNODB for an existing table. See Chapter 15, The InnoDB Storage Engine for more details about this storage engine.

- Optimize SELECT statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.

- Start mysqld with --low-priority-updates. For storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE), this gives all statements that update (modify) a table lower priority than SELECT statements. In this case, the second SELECT statement in the preceding scenario would execute before the UPDATE statement, and would not wait for the first SELECT to finish.

- To specify that all updates issued in a specific connection should be done with low priority, set the low_priority_updates server system variable equal to 1.

- To give a specific INSERT, UPDATE, or DELETE statement lower priority, use the LOW_PRIORITY attribute.
• To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See Section 13.2.10, “SELECT Syntax”.

• Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This permits `READ` locks after a certain number of `WRITE` locks.

• If you have problems with `INSERT` combined with `SELECT`, consider switching to `MyISAM` tables, which support concurrent `SELECT` and `INSERT` statements. (See Section 8.11.3, “Concurrent Inserts”.)

• If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See Section 13.2.2, “DELETE Syntax”.

• Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See Section 13.2.10, “SELECT Syntax”.

• Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.

• You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

8.11.3 Concurrent Inserts

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.4.4, “The Binary Log”. In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

8.11.4 Metadata Locking
Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, and scheduled events), and tablespaces.

The Performance Schema `metadata_locks` table exposes metadata lock information, which can be useful for seeing which sessions hold locks, are blocked waiting for locks, and so forth. For details, see Section 26.12.12.3, “The metadata_locks Table”.

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.

- Metadata Lock Acquisition
- Metadata Lock Release

**Metadata Lock Acquisition**

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the `max_write_lock_count` system variable. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, `LOCK TABLES`, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, `RENAME TABLE` is a DDL statement that acquires locks in name order:

- This `RENAME TABLE` statement renames `tbla` to something else, and renames `tblc` to `tbla`:

  ```
  RENAME TABLE tbla TO tbld, tblc TO tbla;
  ```

  The statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tbld` (because `tbld` follows `tblc` in name order):

- This slightly different statement also renames `tbla` to something else, and renames `tblc` to `tbla`:

  ```
  RENAME TABLE tbla TO tblb, tblc TO tbla;
  ```

  In this case, the statement acquires metadata locks, in order, on `tbla`, `tblb`, and `tblc` (because `tblb` precedes `tblc` in name order):

  Both statements acquire locks on `tbla` and `tblc`, in that order, but differ in whether the lock on the remaining table name is acquired before or after `tblc`.
Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.

Begin with two tables `x` and `x_new` that have identical structure. Three clients issue statements that involve these tables:

Client 1:

```sql
LOCK TABLE x WRITE, x_new WRITE;
```

The statement requests and acquires write locks in name order on `x` and `x_new`.

Client 2:

```sql
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```sql
RENAME TABLE x TO x_old, x_new TO x;
```

The statement requests exclusive locks in name order on `x`, `x_new`, and `x_old`, but blocks waiting for the lock on `x`.

Client 1:

```sql
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `x_new`. The exclusive lock request for `x` by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on `x`, then also on `x_new` and `x_old`, performs the renaming, and releases its locks. Client 2 then acquires its lock on `x`, performs the insert, and releases its lock.

Lock acquisition order results in the `RENAME TABLE` executing before the `INSERT`. The `x` into which the insert occurs is the table that was named `x_new` when Client 2 issued the insert and was renamed to `x` by Client 3:

```sql
mysql> SELECT * FROM x;
+---+
| i |
+---+
mysql> SELECT * FROM x_old;
Empty set (0.01 sec)
```

Now begin instead with tables named `x` and `new_x` that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

```sql
LOCK TABLE x WRITE, new_x WRITE;
```

The statement requests and acquires write locks in name order on `new_x` and `x`.

Client 2:
INSERT INTO x VALUES(1);

The statement requests and blocks waiting for a write lock on x.

Client 3:

RENAME TABLE x TO old_x, new_x TO x;

The statement requests exclusive locks in name order on new_x, old_x, and x, but blocks waiting for the lock on new_x.

Client 1:

UNLOCK TABLES;

The statement releases the write locks on x and new_x. For x, the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For new_x, the only pending request is by Client 3, which is permitted to acquire that lock (and also the lock on old_x). The rename operation still blocks for the lock on x until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on x, performs the rename, and releases its lock.

In this case, lock acquisition order results in the INSERT executing before the RENAME TABLE. The x into which the insert occurs is the original x, now renamed to old_x by the rename operation:

mysql> SELECT * FROM x;
Empty set (0.01 sec)

mysql> SELECT * FROM old_x;
+-----+
| i    |
+-----+
| 1    |
+-----+

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

Metadata locks are extended, as necessary, to tables related by a foreign key constraint to prevent conflicting DML and DDL operations from executing concurrently on the related tables. When updating a parent table, a metadata lock is taken on the child table while updating foreign key metadata. Foreign key metadata is owned by the child table.

**Metadata Lock Release**

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table t and nontransactional table nt as follows:
External Locking

```sql
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```sql
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

The same behavior applies for the `LOCK TABLES ... READ`. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) will block and be blocked by `LOCK TABLES ... READ` for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

As of MySQL 8.0.13, for XA transactions in `PREPARED` state, metadata locks are maintained across client disconnects and server restarts, until an `XA COMMIT` or `XA ROLLBACK` is executed.

### 8.11.5 External Locking

External locking is the use of file system locking to manage contention for MyISAM database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.

- If you use `myisamchk` to perform table maintenance operations on MyISAM tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack MyISAM tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you _must_ always ensure that the `mysqld` server is not using the table. If you do not stop `mysqld`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables _may become corrupted_ if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).
External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only read tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See System Factors.) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to MyISAM tables from many MySQL processes, do not start the server with the `--delay-key-write=ALL` option or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy this condition is to always use `--external-locking` together with `--delay-key-write=OFF`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

---

**8.12 Optimizing the MySQL Server**

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

**8.12.1 Optimizing Disk I/O**

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an InnoDB configuration to improve I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.

- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:

  - Using symbolic links

    This means that, for MyISAM tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 8.12.2, “Using Symbolic Links”.

---
Optimizing Disk I/O

Symbolic links are not supported for use with InnoDB tables. However, it is possible to place InnoDB data and log files on different physical disks. For more information, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the $N$-th block on the ($N \mod \text{number_of_disks}$) disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 8.13.2, “Using Your Own Benchmarks”.

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

• For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need $2 \times N$ drives to hold $N$ drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

• A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID $N$ disk. RAID $N$ can be a problem if you have many writes, due to the time required to update the parity bits.

• You can also set the parameters for the file system that the database uses:

  If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the --noatime option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

  On many operating systems, you can set a file system to be updated asynchronously by mounting it with the --async option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

Using NFS with MySQL

Caution is advised when considering using NFS with MySQL. Potential issues, which vary by operating system and NFS version, include:

• MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.

• Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with hard and intr mount options.

• Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.
If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.

### 8.12.2 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For **InnoDB** tables, use the `DATA DIRECTORY` clause on the `CREATE TABLE` statement instead of symbolic links, as explained in Section 15.6.3.6, "Creating a Tablespace Outside of the Data Directory". This new feature is supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink **MyISAM** tables only as a last resort.

To determine the location of your data directory, use this statement:

```sql
SHOW VARIABLES LIKE 'datadir';
```

#### 8.12.2.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```bash
mkdir /dr1/databases/test
l ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```bash
cd /path/to/datadir
l ln -s db1 db2
```

The result is that, for any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

#### 8.12.2.2 Using Symbolic Links for MyISAM Tables on Unix

**Note**

Symbolic link support as described here, along with the the `--symbolic-links` option that controls it, is deprecated and will be removed in a future version of MySQL. In addition, the option is disabled by default.

Symlinks are fully supported only for **MyISAM** tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For **InnoDB** tables, use the alternative technique explained in Section 15.6.3.6, "Creating a Tablespace Outside of the Data Directory" instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```bash
...
SHOW VARIABLES LIKE 'have_symlink';

The handling of symbolic links for MyISAM tables works as follows:

- In the data directory, you always have the data (.MYD) file and the index (.MYI) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks.

- You can symlink the data file and the index file independently to different directories.

- To instruct a running MySQL server to perform the symlink, use the DATA DIRECTORY and INDEX DIRECTORY options to CREATE TABLE. See Section 13.1.20, “CREATE TABLE Syntax”. Alternatively, if mysqld is not running, symlinking can be accomplished manually using ln -s from the command line.

Note

The path used with either or both of the DATA DIRECTORY and INDEX DIRECTORY options may not include the MySQL data directory. (Bug #32167)

- mysamchk does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the ALTER TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements.

Note

When you drop a table that is using symlinks, both the symlink and the file to which the symlink points are dropped. This is an extremely good reason not to run mysql as the system root or permit system users to have write access to MySQL database directories.

- If you rename a table with ALTER TABLE ... RENAME or RENAME TABLE and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you use ALTER TABLE ... RENAME or RENAME TABLE to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you are not using symlinks, start mysql with the --skip-symbolic-links option to ensure that no one can use mysql to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- ALTER TABLE ignores the DATA DIRECTORY and INDEX DIRECTORY table options.

8.12.2.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named mydb at D:\data\mydb. To do this, create a symbolic link in the MySQL data directory that points to D:\data\mydb. However, before creating the symbolic link, make sure that the D:\data\mydb directory exists by creating it if necessary. If you already have a database directory named mydb in the data directory, move it to D:\data. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.
On Windows, you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Change location into the data directory:

   ```
   C:\> cd \path\to\datadir
   ```

2. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

   ```
   C:\> mklink /d mydb D:\data\mydb
   ```

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

8.12.3 Optimizing Memory Use

8.12.3.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to permit a MySQL server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The **InnoDB** buffer pool is a memory area that holds cached **InnoDB** data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. For more information, see Section 15.5.1, “Buffer Pool”.

  The size of the buffer pool is important for system performance:

  - **InnoDB** allocates memory for the entire buffer pool at server startup, using `malloc()` operations. The `innodb_buffer_pool_size` system variable defines the buffer pool size. Typically, a recommended `innodb_buffer_pool_size` value is 50 to 75 percent of system memory. `innodb_buffer_pool_size` can be configured dynamically, while the server is running. For more information, see Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”.

  - On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The `innodb_buffer_pool_instances` system variable defines the number of buffer pool instances.

  - A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.

  - A buffer pool that is too large may cause swapping due to competition for memory.

  - The storage engine interface enables the optimizer to provide information about the size of the record buffer to be used for scans that the optimizer estimates will read multiple rows. The buffer size can vary based on the size of the estimate. **InnoDB** uses this variable-size buffering capability to take advantage of row prefetching, and to reduce the overhead of latching and B-tree navigation.

  - All threads share the **MyISAM** key buffer. The `key_buffer_size` system variable determines its size.
For each MyISAM table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure, column structures for each column, and a buffer of size $3 \times N$ are allocated (where $N$ is the maximum row length, not counting BLOB columns). A BLOB column requires five to eight bytes plus the length of the BLOB data. The MyISAM storage engine maintains one extra row buffer for internal use.

- The myisam_use_mmap system variable can be set to 1 to enable memory-mapping for all MyISAM tables.

- If an internal in-memory temporary table becomes too large (as determined using the tmp_table_size and max_heap_table_size system variables), MySQL automatically converts the table from in-memory to on-disk format. On-disk temporary tables use the storage engine defined by the internal_tmp_disk_storage_engine system variable. You can increase the permissible temporary table size as described in Section 8.4.4, "Internal Temporary Table Use in MySQL".

For MEMORY tables explicitly created with CREATE TABLE, only the max_heap_table_size system variable determines how large a table can grow, and there is no conversion to on-disk format.

- The MySQL Performance Schema is a feature for monitoring MySQL server execution at a low level. The Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see Section 26.17, "The Performance Schema Memory-Allocation Model".

- Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:
  - A stack (thread_stack)
  - A connection buffer (net_buffer_length)
  - A result buffer (net_buffer_length)

The connection buffer and result buffer each begin with a size equal to net_buffer_length bytes, but are dynamically enlarged up to max_allowed_packet bytes as needed. The result buffer shrinks to net_buffer_length bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

Each connection thread uses memory for computing statement digests. The server allocates max_digest_length bytes per session. See Section 26.10, "Performance Schema Statement Digests and Sampling".

- All threads share the same base memory.

- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.

- Each request that performs a sequential scan of a table allocates a read buffer. The read_buffer_size system variable determines the buffer size.

- When reading rows in an arbitrary sequence (for example, following a sort), a random-read buffer may be allocated to avoid disk seeks. The read_rnd_buffer_size system variable determines the buffer size.

- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain BLOB columns are stored on disk.
Optimizing Memory Use

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section B.6.3.5, “Where MySQL Stores Temporary Files”.

- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.

- For each table having BLOB columns, a buffer is enlarged dynamically to read in larger BLOB values. If you scan a table, the buffer grows as large as the largest BLOB value.

- MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The table_open_cache system variable defines the initial table cache size; see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

MySQL also requires memory for the table definition cache. The table_definition_cache system variable defines the number of table definitions that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A FLUSH TABLES statement or mysqladmin flush-tables command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. FLUSH TABLES does not return until all tables have been closed.

- The server caches information in memory as a result of GRANT, CREATE USER, CREATE SERVER, and INSTALL PLUGIN statements. This memory is not released by the corresponding REVOKE, DROP USER, DROP SERVER, and UNINSTALL PLUGIN statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with FLUSH PRIVILEGES.

In a replication topology, the following settings affect memory usage, and can be adjusted as required:

- The max_allowed_packet system variable on a replication master limits the maximum message size that the master sends to its slaves for processing. This setting defaults to 64M.

- The slave_pending_jobs_size_max system variable on a multi-threaded slave sets the maximum amount of memory that is made available for holding messages awaiting processing. This setting defaults to 128M. The memory is only allocated when needed, but it might be used if your replication topology handles large transactions sometimes. It is a soft limit, and larger transactions can be processed.

- The rpl_read_size system variable on a replication master or slave controls the minimum amount of data in bytes that is read from the binary log files and relay log files. The default is 8192 bytes. A buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on masters and coordinator threads on slaves.

- The binlog_transaction_dependency_history_size system variable limits the number of row hashes held as an in-memory history.

- The max_binlog_cache_size system variable specifies the upper limit of memory usage by an individual transaction.

- The max_binlog_stmt_cache_size system variable specifies the upper limit of memory usage by the statement cache.

ps and other system status programs may report that mysqld uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of ps counts the unused
Optimizing Memory Use

memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

**Monitoring MySQL Memory Usage**

The following example demonstrates how to use Performance Schema and `sys schema` to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the `ENABLED` column of the Performance Schema `setup_instruments` table. Memory instruments have names in the form of `memory/code_area/instrument_name`, where `code_area` is a value such as `sql` or `innodb`, and `instrument_name` is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema `setup_instruments` table. The following query returns hundreds of memory instruments for all code areas.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%memory%';
```

You can narrow results by specifying a code area. For example, you can limit results to InnoDB memory instruments by specifying `innodb` as the code area.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%memory/innodb%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory/innodb/adaptive hash index</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/buf_buf_pool</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/dict_stats_bg_recalc_pool_t</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/dict_stats_index_map_t</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/dict_stats_n_diff_on_level</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/other</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/row_log_buf</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/row_merge_sort</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/std</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>memory/innodb/trx_sys_t::rw_trx_ids</td>
<td>NO</td>
<td>NO</td>
</tr>
</tbody>
</table>

Depending on your MySQL installation, code areas may include `performance_schema`, `sql`, `client`, `innodb`, `myisam`, `csv`, `memory`, `blackhole`, `archive`, `partition`, and others.

2. To enable memory instruments, add a `performance-schema-instrument` rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

```
performance-schema-instrument='memory/%=COUNTED'
```

**Note**

Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

After restarting the server, the `ENABLED` column of the Performance Schema `setup_instruments` table should report YES for memory instruments that you enabled. The `TIMED` column in the `setup_instruments` table is ignored for memory instruments because memory operations are not timed.
3. Query memory instrument data. In this example, memory instrument data is queried in the Performance Schema `memory_summary_global_by_event_name` table, which summarizes data by `EVENT_NAME`. The `EVENT_NAME` is the name of the instrument.

The following query returns memory data for the InnoDB buffer pool. For column descriptions, see Section 26.12.16.10, “Memory Summary Tables”.

```sql
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool';
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>COUNT_ALLOC</th>
<th>COUNT_FREE</th>
<th>SUM_NUMBER_OF_BYTES_ALLOC</th>
<th>SUM_NUMBER_OF_BYTES_FREE</th>
<th>LOW_COUNT_USED</th>
<th>CURRENT_COUNT_USED</th>
<th>HIGH_COUNT_USED</th>
<th>LOW_NUMBER_OF_BYTES_USED</th>
<th>CURRENT_NUMBER_OF_BYTES_USED</th>
<th>HIGH_NUMBER_OF_BYTES_USED</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory/innodb/buf_buf_pool</td>
<td>1</td>
<td>0</td>
<td>137428992</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>137428992</td>
<td>0</td>
<td>137428992</td>
<td>137428992</td>
</tr>
</tbody>
</table>

The same underlying data can be queried using the `sys` schema `memory_global_by_current_bytes` table, which shows current memory usage within the server globally, broken down by allocation type.

```sql
mysql> SELECT * FROM sys.memory_global_by_current_bytes
WHERE event_name LIKE 'memory/innodb/buf_buf_pool';
```

```
+----------------+----------------+-------------------+-------------------+-------------------+----------------+-------------------+-------------------+-------------------+-------------------+-------------------+
| event_name      | current_count  | current_alloc     | current_avg_alloc | high_count        | high_alloc      | high_avg_alloc    | low_count         | low_alloc         | low_avg_alloc      |
|----------------+----------------+-------------------+-------------------+-------------------+----------------+-------------------+-------------------+-------------------+-------------------+-------------------|
| memory/innodb/buf_buf_pool | 1 | 131.06 MiB | 131.06 MiB | 1 | 131.06 MiB | 131.06 MiB | 0 | 0 | 0 |
```

This `sys` schema query aggregates currently allocated memory (`current_alloc`) by code area:

```sql
mysql> SELECT SUBSTRING_INDEX(event_name,'/',2) AS code_area, sys.format_bytes(SUM(current_alloc)) AS current_alloc
FROM sys.$memory_global_by_current_bytes
GROUP BY SUBSTRING_INDEX(event_name,'/',2)
ORDER BY SUM(current_alloc) DESC;
```

<table>
<thead>
<tr>
<th>code_area</th>
<th>current_alloc</th>
</tr>
</thead>
</table>
8.12.3.2 Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:       0
HugePages_Free:        0
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
shell> cat
```

# Set the number of pages to be used.
Optimizing Network Use

Each page is normally 2MB, so a value of 20 = 40MB.
This command actually allocates memory, so this much memory must be available.
```
echo 20 > /proc/sys/vm/nr_hugepages
```
Set the group number that is permitted to access this memory (102 in this case). The mysql user must be a member of this group.
```
echo 102 > /proc/sys/vm/hugetlb_shm_group
```
Increase the amount of shmem permitted per segment (12G in this case).
```
echo 1560281088 > /proc/sys/kernel/shmmax
```
Increase total amount of shared memory. The value is the number of pages. At 4KB/page, 4194304 = 16GB.
```
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:
```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an “unlimited” value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:
```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in the server `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, InnoDB uses large pages automatically for its buffer pool and additional memory pool. If InnoDB cannot do this, it falls back to use of traditional memory and writes a warning to the error log:
```
Warning: Using conventional memory pool
```

To verify that large pages are being used, check `/proc/meminfo` again:
```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        2
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

8.12.4 Optimizing Network Use
8.12.4.1 How MySQL Handles Client Connections

This section describes aspects of how the MySQL server manages client connections.

- **Network Interfaces and Connection Manager Threads**
- **Client Connection Thread Management**
- **Connection Volume Management**
- **Administrative Connection Management**

### Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.
- On Unix, the same manager thread also handles Unix socket file connection requests.
- On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.
- On all platforms, an additional network interface may be enabled to accept administrative TCP/IP connection requests. This interface can use the manager thread that handles “ordinary” TCP/IP requests, or a separate thread.

The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

### Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.6.3, “MySQL Enterprise Thread Pool”.

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See Section 5.1.8, “Server System Variables”, and Section 5.1.10, “Server Status Variables”.)
The `thread_cache_size` system variable determines the thread cache size. By default, the server autosizes the value at startup, but it can be set explicitly to override this default. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable \( N \) inactive connection threads to be cached, set `thread_cache_size` to \( N \) at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.

To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the `Threads_cached` and `Threads_created` status variables.

When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of \( N \) bytes for each thread, start the server with `thread_stack` set to \( N \) at server startup.

**Connection Volume Management**

To control the maximum number of clients the server permits to connect simultaneously, set the `max_connections` system variable at server startup or at runtime. It may be necessary to increase `max_connections` if more clients attempt to connect simultaneously then the server is configured to handle (see Section B.6.2.6, “Too many connections”).

`mysql` actually permits `max_connections + 1` client connections. The extra connection is reserved for use by accounts that have the `CONNECTION_ADMIN` or `SUPER` privilege. By granting the privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.6.29, “SHOW PROCESSLIST Syntax”. (The server also permits administrative connections on a dedicated interface. See Administrative Connection Management.)

If the server refuses a connection because the `max_connections` limit is reached, it increments the `Connection_errors_max_connections` status variable.

The maximum number of connections MySQL supports (that is, the maximum value to which `max_connections` can be set) depends on several factors:

- The quality of the thread library on a given platform.
- The amount of RAM available.
- The amount of RAM is used for each connection.
- The workload from each connection.
- The desired response time.
- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the `max_connections` value increases the number of file descriptors that `mysql` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. For comments on file descriptor limits, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

Increasing `--open-files-limit` may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system
Optimizing Network Use

documentation to determine whether it is possible to increase the limit and how to do so. See also Section B.6.2.17, “File Not Found and Similar Errors”.

Administrative Connection Management

As of MySQL 8.0.14, the server permits a TCP/IP port to be configured specifically for administrative connections. This provides an alternative to the single administrative connection that is permitted on the network interfaces used for ordinary connections even when max_connections connections are already established (see Connection Volume Management).

The administrative network interface has these characteristics:

• The interface is available only if the admin_address system variable is set at startup to indicate the IP address for the administrative interface. If no admin_address value value is specified, the server maintains no administrative interface.

• The admin_port system variable specifies the interface TCP/IP port number (default 33062).

• There is no limit on the number of administrative connections.

• Connections are permitted only by users who have the SERVICE_CONNECTION_ADMIN privilege.

The create_admin_listener_thread system variable enables DBAs to choose at startup whether the administrative interface is implemented using the listener thread used for ordinary connections, or has its own separate thread. The default is to implement the administrative interface using the listener thread used for ordinary connections.

8.12.4.2 DNS Lookup Optimization and the Host Cache

The MySQL server maintains a host cache in memory that contains information about clients: IP address, host name, and error information. The Performance Schema host_cache table exposes the contents of the host cache so that it can be examined using SELECT statements. This may help you diagnose the causes of connection problems. See Section 26.12.17.1, “The host_cache Table”.

Note

The server uses the host cache only for nonlocal TCP connections. It does not use the cache for TCP connections established using a loopback interface address (for example, 127.0.0.1 or ::1), or for connections established using a Unix socket file, named pipe, or shared memory.

• Host Cache Operation

• Host Cache Configuration

Host Cache Operation

The server uses the host cache for several purposes:

• By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.

• The cache contains information about errors that occur during the connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The max_connect_errors
system variable determines the permitted number of successive errors before blocking occurs (see Section B.6.2.5, “Host 'host_name' is blocked”).

For each new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new cache entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to NULL and the flag is false. This entry is also used for subsequent client TCP connections from the same originating IP.

2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name-to-IP DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains NULL and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (In this case, another DNS resolution attempt occurs the next time a client connects from this IP.)

3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see Section 26.12.17.1, “The host_cache Table”.

The server performs host name resolution using the gethostbyaddr() and gethostbyname() system calls.

To unblock blocked hosts, flush the host cache by executing a FLUSH HOSTS statement, a TRUNCATE TABLE statement that truncates the Performance Schema host_cache table, or a mysqladmin flush-hosts command. FLUSH HOSTS and mysqladmin flush-hosts require the RELOAD privilege. TRUNCATE TABLE requires the DROP privilege for the host_cache table.

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts has occurred since the last connection attempt from the blocked host. This can occur because the server discards the least recently used cache entry to make room for a new entry if the cache is full when a connection arrives from a client IP not in the cache. If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the Connection_errors_xxx status variables (see Section 5.1.10, “Server Status Variables”).

**Host Cache Configuration**

The host cache is enabled by default. The host_cache_size system variable controls its size, as well as the size of the Performance Schema host_cache table that exposes the cache contents. The cache size can be set at server startup and changed at runtime. For example, to set the size to 100 at startup, put these lines in the server my.cnf file:

```
To change the size to 300 at runtime, do this:

```
SET GLOBAL host_cache_size=300;
```

Setting `host_cache_size` to 0, either at server startup or at runtime, disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

Changing the cache size at runtime causes an implicit `FLUSH HOSTS` operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with `--skip-host-cache` does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0 at runtime.

To disable DNS host name lookups, start the server with the `--skip-name-resolve` option. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by disabling DNS lookups with `--skip-name-resolve` or by increasing the value of `host_cache_size` to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the `--skip-networking` option.

### 8.12.5 Resource Groups

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. Group attributes enable control over its resources, to enable or restrict resource consumption by threads in the group. DBAs can modify these attributes as appropriate for different workloads.

Currently, CPU time is a manageable resource, represented by the concept of “virtual CPU” as a term that includes CPU cores, hyperthreads, hardware threads, and so forth. The server determines at startup how many virtual CPUs are available, and database administrators with appropriate privileges can associate these CPUs with resource groups and assign threads to groups.

For example, to manage execution of batch jobs that need not execute with high priority, a DBA can create a Batch resource group, and adjust its priority up or down depending on how busy the server is. (Perhaps batch jobs assigned to the group should run at lower priority during the day and at higher priority during the night.) The DBA can also adjust the set of CPUs available to the group. Groups can be enabled or disabled to control whether threads are assignable to them.

The following sections describe aspects of resource group use in MySQL:

- Resource Group Components
- Resource Group Attributes
- Resource Group Management
• Resource Group Replication
• Resource Group Restrictions

---

**Important**

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations. In particular, Linux systems might require a manual step for some installation methods. For details, see Resource Group Restrictions.

---

**Resource Group Components**

These capabilities provide the SQL interface for resource group management in MySQL:

• SQL statements enable creating, altering, and dropping resource groups, and enable assigning threads to resource groups. An optimizer hint enables assigning individual statements to resource groups.
• Resource group privileges provide control over which users can perform resource group operations.
• The `INFORMATION_SCHEMA.RESOURCE_GROUPS` table exposes information about resource group definitions and the Performance Schema `threads` table shows the resource group assignment for each thread.
• Status variables provide execution counts for each management SQL statement.

---

**Resource Group Attributes**

Resource groups have attributes that define the group. All attributes can be set at group creation time. Some attributes are fixed at creation time; others can be modified any time thereafter.

These attributes are defined at resource group creation time and cannot be modified:

• Each group has a name. Resource group names are identifiers like table and column names, and need not be quoted in SQL statements unless they contain special characters or are reserved words. Group names are not case sensitive and may be up to 64 characters long.
• Each group has a type, which is either `SYSTEM` or `USER`. The resource group type affects the range of priority values assignable to the group, as described later. This attribute together with the differences in permitted priorities enables system threads to be identified so as to protect them from contention for CPU resources against user threads.

System and user threads correspond to background and foreground threads as listed in the Performance Schema `threads` table.

These attributes are defined at resource group creation time and can be modified any time thereafter:

• The CPU affinity is the set of virtual CPUs the resource group can use. An affinity can be any nonempty subset of the available CPUs. If a group has no affinity, it can use all available CPUs.
• The thread priority is the execution priority for threads assigned to the resource group. Priority values range from -20 (highest priority) to 19 (lowest priority). The default priority is 0, for both system and user groups.

System groups are permitted a higher priority than user groups, ensuring that user threads never have a higher priority than system threads:

• For system resource groups, the permitted priority range is -20 to 0.
• For user resource groups, the permitted priority range is 0 to 19.

• Each group can be enabled or disabled, affording administrators control over thread assignment. Threads can be assigned only to enabled groups.

Resource Group Management

By default, there is one system group and one user group, named **SYS_default** and **USR_default**, respectively. These default groups cannot be dropped and their attributes cannot be modified. Each default group has no CPU affinity and priority 0.

Newly created system and user threads are assigned to the **SYS_default** and **USR_default** groups, respectively.

For user-defined resource groups, all attributes are assigned at group creation time. After a group has been created, its attributes can be modified, with the exception of the name and type attributes.

To create and manage user-defined resource groups, use these SQL statements:

• **CREATE RESOURCE GROUP** creates a new group. See Section 13.7.2.2, “CREATE RESOURCE GROUP Syntax”.

• **ALTER RESOURCE GROUP** modifies an existing group. See Section 13.7.2.1, “ALTER RESOURCE GROUP Syntax”.

• **DROP RESOURCE GROUP** drops an existing group. See Section 13.7.2.3, “DROP RESOURCE GROUP Syntax”.

Those statements require the **RESOURCE_GROUP_ADMIN** privilege.

To manage resource group assignments, use these capabilities:

• **SET RESOURCE GROUP** assigns threads to a group. See Section 13.7.2.4, “SET RESOURCE GROUP Syntax”.

• The **RESOURCE_GROUP** optimizer hint assigns individual statements to a group. See Section 8.9.2, “Optimizer Hints”.

Those operations require the **RESOURCE_GROUP_ADMIN** or **RESOURCE_GROUP_USER** privilege.

Resource group definitions are stored in the **resource_groups** data dictionary table so that groups persist across server restarts. Because **resource_groups** is part of the data dictionary, it is not directly accessible by users. Resource group information is available using the **INFORMATION_SCHEMA.RESOURCE_GROUPS** table, which is implemented as a view on the data dictionary table. See Section 25.22, “The INFORMATION_SCHEMA RESOURCE_GROUPS Table”.

Initially, the **RESOURCE_GROUPS** table has these rows describing the default groups:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS\G
*************************** 1. row ***************************
 RESOURCE_GROUP_NAME: USR_default
 RESOURCE_GROUP_TYPE: USER
 RESOURCE_GROUP_ENABLED: 1
 VCPU_IDS: 0-3
 THREAD_PRIORITY: 0
*************************** 2. row ***************************
```
The `THREAD_PRIORITY` values are 0, indicating the default priority. The `VCPU_IDS` values show a range comprising all available CPUs. For the default groups, the displayed value varies depending on the system on which the MySQL server runs.

Earlier discussion mentioned a scenario involving a resource group named `Batch` to manage execution of batch jobs that need not execute with high priority. To create such a group, use a statement similar to this:

```
CREATE RESOURCE GROUP Batch
  TYPE = USER
  VCPU = 2-3            -- assumes a system with at least 4 CPUs
  THREAD_PRIORITY = 10;
```

To verify that the resource group was created as expected, check the `RESOURCE_GROUPS` table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS
    WHERE RESOURCE_GROUP_NAME = 'Batch'
G
*************************** 1. row ***************************
 RESOURCE_GROUP_NAME: Batch
 RESOURCE_GROUP_TYPE: USER
 RESOURCE_GROUP_ENABLED: 1
 VCPU_IDS: 2-3
 THREAD_PRIORITY: 10
```

If the `THREAD_PRIORITY` value is 0 rather than 10, check whether your platform or system configuration limits the resource group capability; see Resource Group Restrictions.

To assign a thread to the `Batch` group, do this:

```
SET RESOURCE GROUP Batch FOR thread_id;
```

Thereafter, statements in the named thread execute with `Batch` group resources.

If a session's own current thread should be in the `Batch` group, execute this statement within the session:

```
SET RESOURCE GROUP Batch;
```

Thereafter, statements in the session execute with `Batch` group resources.

To execute a single statement using the `Batch` group, use the `RESOURCE_GROUP` optimizer hint:

```
INSERT /*+ RESOURCE_GROUP(Batch) */ INTO t2 VALUES(2);
```

Threads assigned to the `Batch` group execute with its resources, which can be modified as desired:

- For times when the system is highly loaded, decrease the number of CPUs assigned to the group, lower its priority, or (as shown) both:

  ```
  ALTER RESOURCE GROUP Batch
  VCPU = 3
  THREAD_PRIORITY = 19;
  ```
Resource Groups

- For times when the system is lightly loaded, increase the number of CPUs assigned to the group, raise its priority, or (as shown) both:

```
ALTER RESOURCE GROUP Batch
  VCPU = 0-3
  THREAD_PRIORITY = 0;
```

**Resource Group Replication**

Resource group management is local to the server on which it occurs. Resource group SQL statements and modifications to the `resource_groups` data dictionary table are not written to the binary log and are not replicated.

**Resource Group Restrictions**

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations:

- Resource groups are unavailable if the thread pool plugin is installed.
- Resource groups are unavailable on macOS, which provides no API for binding CPUs to a thread.
- On FreeBSD and Solaris, resource group thread priorities are ignored. (Effectively, all threads run at priority 0.) Attempts to change priorities result in a warning:

```
mysql> ALTER RESOURCE GROUP abc THREAD_PRIORITY = 10;
Query OK, 0 rows affected, 1 warning (0.18 sec)
mysql> SHOW WARNINGS;
+---------+------+-------------------------------------------------------------+
| Level   | Code | Message                                                     |
|---------+------|-------------------------------------------------------------|
| Warning | 4560 | Attribute thread_priority is ignored (using default value). |
+---------+------+-------------------------------------------------------------+
```

- On Linux, resource groups thread priorities are ignored unless the `CAP_SYS_NICE` capability is set. Granting `CAP_SYS_NICE` capability to a process enables a range of privileges; consult [http://man7.org/linux/man-pages/man7/capabilities.7.html](http://man7.org/linux/man-pages/man7/capabilities.7.html) for the full list. Please be careful when enabling this capability.

On Linux platforms using systemd and kernel support for Ambient Capabilities (Linux 4.3 or newer), the recommended way to enable `CAP_SYS_NICE` capability is to modify the MySQL service file and leave the `mysqld` binary unmodified. To adjust the service file for MySQL, use this procedure:

1. Run the appropriate command for your platform:
   - Oracle Linux, Red Hat, and Fedora systems:
     ```
     shell> sudo systemctl edit mysqld
     ```
   - SUSE, Ubuntu, and Debian systems:
     ```
     shell> sudo systemctl edit mysql
     ```

2. Using an editor, add the following text to the service file:

   ```
   [Service]
   AmbientCapabilities=CAP_SYS_NICE
   ```
3. Restart the MySQL service.

If you cannot enable the `CAP_SYS_NICE` capability as just described, it can be set manually using the `setcap` command, specifying the path name to the `mysqld` executable (this requires `sudo` access). You can check the capabilities using `getcap`. For example:

```
shell> sudo setcap cap_sys_nice+ep /path/to/mysqld
shell> getcap /path/to/mysqld
    /path/to/mysqld = cap_sys_nice+ep
```

As a safety measure, restrict execution of the `mysqld` binary to the `root` user and users with `mysql` group membership:

```
shell> sudo chown root:mysql /path/to/mysqld
shell> sudo chmod 0750 /path/to/mysqld
```

**Important**

If manual use of `setcap` is required, it must be performed after each reinstall.

- On Windows, threads run at one of five thread priority levels. The resource group thread priority range of -20 to 19 maps onto those levels as indicated in the following table.

**Table 8.3 Resource Group Thread Priority on Windows**

<table>
<thead>
<tr>
<th>Priority Range</th>
<th>Windows Priority Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>-20 to -10</td>
<td>THREAD_PRIORITY_HIGHEST</td>
</tr>
<tr>
<td>-9 to -1</td>
<td>THREAD_PRIORITY_ABOVE_NORMAL</td>
</tr>
<tr>
<td>0</td>
<td>THREAD_PRIORITY_NORMAL</td>
</tr>
<tr>
<td>1 to 10</td>
<td>THREAD_PRIORITY BELOW_NORMAL</td>
</tr>
<tr>
<td>11 to 19</td>
<td>THREAD_PRIORITY_LOWEST</td>
</tr>
</tbody>
</table>

8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a "workload") works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.

- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.

- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.

- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The most important feature to try with each workload is the adaptive hash index for InnoDB tables.
This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expr)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```sql
mysql> SELECT BENCHMARK(1000000,1+1);
+------------------------+
<table>
<thead>
<tr>
<th>BENCHMARK(1000000,1+1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------------+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 8.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See Section 4.5.8, “mysqlslap — Load Emulation Client”.
- You can also try benchmarking packages such as SysBench and DBT2, available at [https://launchpad.net/sysbench](https://launchpad.net/sysbench) and [http://osdldbt.sourceforge.net/#dbt2](http://osdldbt.sourceforge.net/#dbt2). These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 8.13.3 Measuring Performance with performance_schema

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See Chapter 26, *MySQL Performance Schema* for details.
8.14 Examining Thread Information

When you are attempting to ascertain what your MySQL server is doing, it can be helpful to examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The `SHOW [FULL] PROCESSLIST` statement: Section 13.7.6.29, “SHOW PROCESSLIST Syntax”
- The `SHOW PROFILE` statement: Section 13.7.6.31, “SHOW PROFILES Syntax”
- The `INFORMATION_SCHEMA PROCESSLIST` table: Section 25.19, “The INFORMATION_SCHEMA PROCESSLIST Table”
- The `mysqladmin processlist` command: Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”

Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the `PROCESS` privilege.

Each process list entry contains several pieces of information:

- **Id** is the connection identifier for the client associated with the thread.
- **User** and **Host** indicate the account associated with the thread.
- **db** is the default database for the thread, or **NULL** if none is selected.
- **Command** and **State** indicate what the thread is doing.
  
  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **Time** indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.

- **Info** contains the text of the statement being executed by the thread, or **NULL** if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use `SHOW FULL PROCESSLIST`.

- The `sys schema processlist` view, which presents information from the Performance Schema `threads` table in a more accessible format: Section 27.4.3.22, “The processlist and x$processlist Views”

- The `sys schema session` view, which presents information about user sessions (like the `sys schema processlist` view, but with background processes filtered out): Section 27.4.3.33, “The session and x$session Views”
The following sections list the possible Command values, and State values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

### 8.14.1 Thread Command Values

A thread can have any of the following Command values:

- **Binlog Dump**
  
  This is a thread on a master server for sending binary log contents to a slave server.

- **Change user**
  
  The thread is executing a change-user operation.

- **Close stmt**
  
  The thread is closing a prepared statement.

- **Connect**
  
  A replication slave is connected to its master.

- **Connect Out**
  
  A replication slave is connecting to its master.

- **Create DB**
  
  The thread is executing a create-database operation.

- **Daemon**
  
  This thread is internal to the server, not a thread that services a client connection.

- **Debug**
  
  The thread is generating debugging information.

- **Delayed insert**
  
  The thread is a delayed-insert handler.

- **Drop DB**
  
  The thread is executing a drop-database operation.

- **Error**

- **Execute**
  
  The thread is executing a prepared statement.

- **Fetch**
  
  The thread is fetching the results from executing a prepared statement.

- **Field List**
  
  The thread is retrieving information for table columns.
• **Init DB**
The thread is selecting a default database.

• **Kill**
The thread is killing another thread.

• **Long Data**
The thread is retrieving long data in the result of executing a prepared statement.

• **Ping**
The thread is handling a server-ping request.

• **Prepare**
The thread is preparing a prepared statement.

• **Processlist**
The thread is producing information about server threads.

• **Query**
The thread is executing a statement.

• **Quit**
The thread is terminating.

• **Refresh**
The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

• **Register Slave**
The thread is registering a slave server.

• **Reset stmt**
The thread is resetting a prepared statement.

• **Set option**
The thread is setting or resetting a client statement-execution option.

• **Shutdown**
The thread is shutting down the server.

• **Sleep**
The thread is waiting for the client to send a new statement to it.

• **Statistics**
The thread is producing server-status information.
• **Table Dump**

  The thread is sending table contents to a slave server.

• **Time**

  Unused.

### 8.14.2 General Thread States

The following list describes thread *State* values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

• **After create**

  This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

• **Analyzing**

  The thread is calculating a *MyISAM* table key distributions (for example, for `ANALYZE TABLE`).

• **checking permissions**

  The thread is checking whether the server has the required privileges to execute the statement.

• **Checking table**

  The thread is performing a table check operation.

• **cleaning up**

  The thread has processed one command and is preparing to free memory and reset certain state variables.

• **closing tables**

  The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

• **converting HEAP to ondisk**

  The thread is converting an internal temporary table from a *MEMORY* table to an on-disk table.

• **copy to tmp table**

  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

  For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See Section 26.12.5, “Performance Schema Stage Event Tables”.

• **Copying to group table**

  If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.
General Thread States

- **Copying to tmp table**
  The server is copying to a temporary table in memory.

- **altering table**
  The server is in the process of executing an in-place `ALTER TABLE`.

- **Copying to tmp table on disk**
  The server is copying to a temporary table on disk. The temporary result set has become too large (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- **Creating index**
  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- **Creating sort index**
  The thread is processing a `SELECT` that is resolved using an internal temporary table.

- **creating table**
  The thread is creating a table. This includes creation of temporary tables.

- **Creating tmp table**
  The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be **Copying to tmp table on disk**.

- **committing alter table to storage engine**
  The server has finished an in-place `ALTER TABLE` and is committing the result.

- **deleting from main table**
  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- **deleting from reference tables**
  The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- **discard_or_import_tablespace**
  The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- **end**
  This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- **executing**
  The thread has begun executing a statement.
• **Execution of init_command**
The thread is executing statements in the value of the `init_command` system variable.

• **freeing items**
The thread has executed a command. This state is usually followed by cleaning up.

• **FULLTEXT initialization**
The server is preparing to perform a natural-language full-text search.

• **init**
This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log and the InnoDB log.

For the end state, the following operations could be happening:

• Writing an event to the binary log

• Freeing memory buffers, including for blobs

• **Killed**
Someone has sent a KILL statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

• **Locking system tables**
The thread is trying to lock a system table (for example, a time zone or log table).

• **logging slow query**
The thread is writing a statement to the slow-query log.

• **login**
The initial state for a connection thread until the client has been authenticated successfully.

• **manage keys**
The server is enabling or disabling a table index.

• **NULL**
This state is used for the `SHOW PROCESSLIST` state.

• **Opening system tables**
The thread is trying to open a system table (for example, a time zone or log table).

• **Opening tables**
The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.
For system tables, the *Opening system tables* state is used instead.

- **optimizing**
  The server is performing initial optimizations for a query.

- **preparing**
  This state occurs during query optimization.

- **Purging old relay logs**
  The thread is removing unneeded relay log files.

- **query end**
  This state occurs after processing a query but before the *freeing items* state.

- **Receiving from client**
  The server is reading a packet from the client.

- **Removing duplicates**
  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- **removing tmp table**
  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- **rename**
  The thread is renaming a table.

- **rename result table**
  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- **Reopen tables**
  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- **Repair by sorting**
  The repair code is using a sort to create indexes.

- **preparing for alter table**
  The server is preparing to execute an in-place `ALTER TABLE`.

- **Repair done**
  The thread has completed a multithreaded repair for a *MyISAM* table.
• **Repair with keycache**
  
The repair code is using creating keys one by one through the key cache. This is much slower than **Repair by sorting**.

• **Rolling back**
  
The thread is rolling back a transaction.

• **Saving state**
  
For **MyISAM** table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the **AUTO_INCREMENT** counter, and key distributions.

• **Searching rows for update**
  
The thread is doing a first phase to find all matching rows before updating them. This has to be done if the **UPDATE** is changing the index that is used to find the involved rows.

• **Sending data**
  
The thread is reading and processing rows for a **SELECT** statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

• **Sending to client**
  
The server is writing a packet to the client.

• **setup**
  
The thread is beginning an **ALTER TABLE** operation.

• **Sorting for group**
  
The thread is doing a sort to satisfy a **GROUP BY**.

• **Sorting for order**
  
The thread is doing a sort to satisfy an **ORDER BY**.

• **Sorting index**
  
The thread is sorting index pages for more efficient access during a **MyISAM** table optimization operation.

• **Sorting result**
  
For a **SELECT** statement, this is similar to **Creating sort index**, but for nontemporary tables.

• **statistics**
  
The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

• **System lock**
  
The thread has called **mysql_lock_tables()** and the thread state has not been updated since. This is a very general state that can occur for many reasons.
General Thread States

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when InnoDB waits for a table-level lock during execution of `LOCK TABLES`. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same `MyISAM` tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option will have no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

For system tables, the `Locking system tables` state is used instead.

- **update**
  The thread is getting ready to start updating the table.

- **Updating**
  The thread is searching for rows to update and is updating them.

- **updating main table**
  The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- **updating reference tables**
  The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- **User lock**
  The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- **User sleep**
  The thread has invoked a `SLEEP()` call.

- **Waiting for commit lock**
  `FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- **Waiting for global read lock**
  `FLUSH TABLES WITH READ LOCK` is waiting for a global read lock or the global `read_only` system variable is being set.

- **Waiting for tables**
  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name, ALTER TABLE, RENAME TABLE, REPAIR TABLE, ANALYZE TABLE, or OPTIMIZE TABLE`.

- **Waiting for table flush**
The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- **Waiting for lock_type lock**

  The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

  This state indicates a wait for a `THR_LOCK`:

- **Waiting for table level lock**

  These states indicate a wait for a metadata lock:

  - **Waiting for event metadata lock**
  - **Waiting for global read lock**
  - **Waiting for schema metadata lock**
  - **Waiting for stored function metadata lock**
  - **Waiting for stored procedure metadata lock**
  - **Waiting for table metadata lock**
  - **Waiting for trigger metadata lock**

  For information about table lock indicators, see Section 8.11.1, “Internal Locking Methods”. For information about metadata locking, see Section 8.11.4, “Metadata Locking”. To see which locks are blocking lock requests, use the Performance Schema lock tables described at Section 26.12.12, “Performance Schema Lock Tables”.

- **Waiting on cond**

  A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- **Writing to net**

  The server is writing a packet to the network.

### 8.14.3 Replication Master Thread States

The following list shows the most common states you may see in the State column for the master’s Binlog Dump thread. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, that no slaves are currently connected.

- **Finished reading one binlog; switching to next binlog**

  The thread has finished reading a binary log file and is opening the next one to send to the slave.
• Master has sent all binlog to slave; waiting for more updates

The thread has read all remaining updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

• Sending binlog event to slave

Binary logs consist of events, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

• Waiting to finalize termination

A very brief state that occurs as the thread is stopping.

8.14.4 Replication Slave I/O Thread States

The following list shows the most common states you see in the State column for a slave server I/O thread. This state also appears in the Slave_IO_State column displayed by SHOW SLAVE STATUS, so you can get a good view of what is happening by using that statement.

• Checking master version

A state that occurs very briefly, after the connection to the master is established.

• Connecting to master

The thread is attempting to connect to the master.

• Queueing master event to the relay log

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

• Reconnecting after a failed binlog dump request

The thread is trying to reconnect to the master.

• Reconnecting after a failed master event read

The thread is trying to reconnect to the master. When connection is established again, the state becomes Waiting for master to send event.

• Registering slave on master

A state that occurs very briefly after the connection to the master is established.

• Requesting binlog dump

A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

• Waiting for its turn to commit

A state that occurs when the slave thread is waiting for older worker threads to commit if slave_preserve_commit_order is enabled.

• Waiting for master to send event
The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- **Waiting for master update**
  The initial state before *Connecting to master.*

- **Waiting for slave mutex on exit**
  A state that occurs briefly as the thread is stopping.

- **Waiting for the slave SQL thread to free enough relay log space**
  You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- **Waiting to reconnect after a failed binlog dump request**
  If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- **Waiting to reconnect after a failed master event read**
  An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

### 8.14.5 Replication Slave SQL Thread States

The following list shows the most common states you may see in the *State* column for a slave server SQL thread:

- **Killing slave**
  The thread is processing a `STOP SLAVE` statement.

- **Making temporary file (append) before replaying LOAD DATA INFILE**
  The thread is executing a `LOAD DATA` statement and is appending the data to a temporary file containing the data from which the slave will read rows.

- **Making temporary file (create) before replaying LOAD DATA INFILE**
  The thread is executing a `LOAD DATA` statement and is creating a temporary file containing the data from which the slave will read rows. This state can only be encountered if the original `LOAD DATA` statement was logged by a master running a version of MySQL lower than MySQL 5.0.3.

- **Reading event from the relay log**
  The thread has read an event from the relay log so that the event can be processed.

- **Slave has read all relay log; waiting for more updates**
  The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.
Replication Slave Connection Thread States

- **Waiting for an event from Coordinator**
  
  Using the multithreaded slave (`slave_parallel_workers` is greater than 1), one of the slave worker threads is waiting for an event from the coordinator thread.

- **Waiting for slave mutex on exit**
  
  A very brief state that occurs as the thread is stopping.

- **Waiting for Slave Workers to free pending events**
  
  This waiting action occurs when the total size of events being processed by Workers exceeds the size of the `slave_pending_jobs_size_max` system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when `slave_parallel_workers` is set greater than 0.

- **Waiting for the next event in relay log**
  
  The initial state before **Reading event from the relay log**.

- **Waiting until MASTER_DELAY seconds after master executed event**
  
  The SQL thread has read an event but is waiting for the slave delay to lapse. This delay is set with the `MASTER_DELAY` option of `CHANGE MASTER TO`.

  The **Info** column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.

### 8.14.6 Replication Slave Connection Thread States

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- **Changing master**
  
  The thread is processing a `CHANGE MASTER TO` statement.

- **Killing slave**
  
  The thread is processing a `STOP SLAVE` statement.

- **Opening master dump table**
  
  This state occurs after **Creating table from master dump**.

- **Reading master dump table data**
  
  This state occurs after **Opening master dump table**.

- **Rebuilding the index on master dump table**
  
  This state occurs after **Reading master dump table data**.

### 8.14.7 NDB Cluster Thread States

- **Committing events to binlog**

- **Opening mysql.ndb_apply_status**
• **Processing events**
The thread is processing events for binary logging.

• **Processing events from schema table**
The thread is doing the work of schema replication.

• **Shutting down**

• **Syncing ndb table schema operation and binlog**
This is used to have a correct binary log of schema operations for NDB.

• **Waiting for allowed to take ndbcluster global schema lock**
The thread is waiting for permission to take a global schema lock.

• **Waiting for event from ndbcluster**
The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.

• **Waiting for first event from ndbcluster**

• **Waiting for ndbcluster binlog update to reach current position**

• **Waiting for ndbcluster global schema lock**
The thread is waiting for a global schema lock held by another thread to be released.

• **Waiting for ndbcluster to start**

• **Waiting for schema epoch**
The thread is waiting for a schema epoch (that is, a global checkpoint).

### 8.14.8 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

• **Clearing**
The scheduler thread or a thread that was executing an event is terminating and is about to end.

• **Initialized**
The scheduler thread or a thread that will execute an event has been initialized.

• **Waiting for next activation**
The scheduler has a nonempty event queue but the next activation is in the future.

• **Waiting for scheduler to stop**
The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

• **Waiting on empty queue**
The scheduler's event queue is empty and it is sleeping.
This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Comments

9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and NULL. The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (') or double quote ("") characters. Examples:

'a string'
"another string"

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:
String Literals

If the ANSI_QUOTES SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A binary string is a string of bytes. Every binary string has a character set and collation named binary. A nonbinary string is a string of characters. It has a character set other than binary and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.)

A character string literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

[_charset_name]'string' [COLLATE collation_name]

Examples:

```
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8'string' COLLATE utf8_danish_ci;
```

You can use N'literal' (or n'literal') to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see Section 10.3.7, “The National Character Set”, and Section 10.3.8, “Character Set Introducers”.

Within a string, certain sequences have special meaning unless the NO_BACKSLASH_ESCAPES SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the escape character. MySQL recognizes the escape sequences shown in Table 9.1, “Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B. Escape processing is done according to the character set indicated by the character_set_connection system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 10.3.6, “Character String Literal Character Set and Collation”.

Table 9.1 Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X’00’) character</td>
</tr>
<tr>
<td>'</td>
<td>A single quote (‘) character</td>
</tr>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
</tbody>
</table>
String Literals

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z); see note following the table</td>
</tr>
<tr>
<td>\</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>%</td>
<td>A % character; see note following the table</td>
</tr>
<tr>
<td>_</td>
<td>A _ character; see note following the table</td>
</tr>
</tbody>
</table>

The ASCII 26 character can be encoded as \Z to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The \\ and \_ sequences are used to search for literal instances of % and _ in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the LIKE operator in Section 12.5.1, “String Comparison Functions”. If you use \\ or \_ outside of pattern-matching contexts, they evaluate to the strings \% and \_, not to % and _.

There are several ways to include quote characters within a string:

- A ' inside a string quoted with ' may be written as ''.
- A " inside a string quoted with " may be written as ".
- Precede the quote character by an escape character (\).
- A ' inside a string quoted with " needs no special treatment and need not be doubled or escaped. In the same way, " inside a string quoted with ' needs no special treatment.

The following SELECT statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '""hello""', 'hel''lo', '\hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+
mysql> SELECT "hello", '\'hello\'', "\"hello\"", "hel"lo", "\hello";
+--------+-------+----------+--------+--------+
| hello' | 'hello' | "hello" | hel'lo | "hello |
+--------+-------+----------+--------+--------+
mysql> SELECT 'This
Is
Four
Lines';
+------------------------+
| This Is Four Lines |
+------------------------+
mysql> SELECT 'disappearing\ backslash';
+-----------------------------+
| disappearing backslash |
+-----------------------------+
```
To insert binary data into a string column (such as a BLOB column), you should represent certain characters by escape sequences. Backslash (\) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape NUL or Control+Z. The mysql client truncates quoted strings containing NUL characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see Table 9.1, “Special Character Escape Sequences”.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the mysql_real_escape_string_quote() C API function to escape characters. See Section 28.7.7.56, “mysql_real_escape_string_quote()”. Within SQL statements that construct other SQL statements, you can use the QUOTE() function. The Perl DBI interface provides a quote method to convert special characters to the proper escape sequences. See Section 28.9, “MySQL Perl API”. Other language interfaces may provide a similar capability.

- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

9.1.2 Numeric Literals

Number literals include exact-value (integer and DECIMAL) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include . as a decimal separator. Numbers may be preceded by – or + to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, –5, –6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E–3, –1.2E3, –1.2E–3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types. For more information about exact-value calculations, see Section 12.25, “Precision Math”.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

9.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of '2015–07–21', '20150721', and 20150721 as a date.
Date and Time Literals

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, consult these sections:

- Section 11.1.2, “Date and Time Type Overview”
- Section 11.3, “Date and Time Types”

**Standard SQL and ODBC Date and Time Literals.** Standard SQL permits temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```sql
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes those constructions and also the corresponding ODBC syntax:

```sql
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

MySQL uses the type keyword and these constructions produce `DATE`, `TIME`, and `DATETIME` values, respectively, including a trailing fractional seconds part if specified. The `TIMESTAMP` syntax produces a `DATETIME` value in MySQL because `DATETIME` has a range that more closely corresponds to the standard SQL `TIMESTAMP` type, which has a year range from 0001 to 9999. (The MySQL `TIMESTAMP` year range is 1970 to 2038.)

**String and Numeric Literals in Date and Time Context.** MySQL recognizes `DATE` values in these formats:

- As a string in either `'YYYY-MM-DD'` or `'YY-MM-DD'` format. A “relaxed” syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, `'2012-12-31'`, `'2012/12/31'`, `'2012^12^31'`, and `'2012@12@31'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDD'` or `'YYMMDD'` format, provided that the string makes sense as a date. For example, `'20070523'` and `'070523'` are interpreted as `'2007-05-23'`, but `'071332'` is illegal (it has nonsensical month and day parts) and becomes `'0000-00-00'`.

- As a number in either `'YYYYMMDD'` or `'YYMMDD'` format, provided that the number makes sense as a date. For example, `'19830905'` and `'830905'` are interpreted as `'1983-09-05'`.

MySQL recognizes `DATETIME` and `TIMESTAMP` values in these formats:

- As a string in either `'YYYY-MM-DD HH:MM:SS'` or `'YY-MM-DD HH:MM:SS'` format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, `'2012-12-31 11:30:45'`, `'2012^12^31 11+30+45'`, `'2012/12/31 11*30*45'`, and `'2012@12@31 11^30^45'` are equivalent.

  The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

  The date and time parts can be separated by `T` rather than a space. For example, `'2012-12-31 11:30:45'` `'2012-12-31T11:30:45'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDDHHMMSS'` or `'YYMMDHHMMSS'` format, provided that the string makes sense as a date. For example, `'20070523091528'` and `'070523091528'` are interpreted as `'2007-05-23 09:15:28'`, but `'071122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.  

• As a number in either `YYYYMDDHHMMSS` or `YMMDDHHMMSS` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as '1983-09-05 13:28:00'.

A **DATETIME** or **TIMESTAMP** value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see **Section 11.3.5, “Fractional Seconds in Time Values”**.

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

• Year values in the range `70-99` are converted to `1970-1999`.

• Year values in the range `00-69` are converted to `2000-2069`.

See also **Section 11.3.7, “Two-Digit Years in Dates”**.

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. '2015-6-9' is the same as '2015-06-09'. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. '2015-10-30 1:2:3' is the same as '2015-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMDDD` or `YYYYMDDHHMMSS` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YMMDD` or `YMMDDHHMMSS` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify '9903', thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are 99 and 03, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value '1999-03-00', use '990300'.

MySQL recognizes **TIME** values in these formats:

• As a string in `'D HH:MM:SS'` format. You can also use one of the following “relaxed” syntaxes: `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34.

• As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, '101112' is understood as '10:11:12', but '109712' is illegal (it has a nonsensical minute part) and becomes '00:00:00'.

• As a number in `HHMMSS` format, provided that it makes sense as a time. For example, 101112 is understood as '10:11:12'. The following alternative formats are also understood: `SS`, `MMSS`, or `HHMMSS`.

A trailing fractional seconds part is recognized in the `'D HH:MM:SS.fraction'`, `'HH:MM:SS.fraction'`, `'HHMMSS.fraction'`, and `HHMMSS.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is
recognized. For information about fractional seconds support in MySQL, see Section 11.3.5, “Fractional Seconds in Time Values”.

For **TIME** values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. '8:3:2' is the same as '08:03:02'.

### 9.1.4 Hexadecimal Literals

Hexadecimal literal values are written using **X'val'** or **0xval** notation, where **val** contains hexadecimal digits (0..9, A..F). Lettercase of the digits and of any leading X does not matter. A leading 0x is case-sensitive and cannot be written as 0X.

#### Legal hexadecimal literals:

- X'01AF'
- X'01af'
- x'01AF'
- x'01af'
- 0x01AF
- 0x01af

#### Illegal hexadecimal literals:

- X'0G'  (G is not a hexadecimal digit)
- 0X01AF  (0X must be written as 0x)

Values written using **X'val'** notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```sql
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near 'X'FFF''
mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using **0xval** notation that contain an odd number of digits are treated as having an extra leading 0. For example, **0xaaa** is interpreted as **0x0aaa**.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```sql
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+---------------+------------------------+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
| MySQL         | binary                 |
+---------------+------------------------+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+--------------+-----------------------+
| 0x5461626c65 | CHARSET(0x5461626c65) |
| Table        | binary                |
+--------------+-----------------------+
```

A hexadecimal literal may have an optional character set introducer and **COLLATE** clause, to designate it as a string that uses a particular character set and collation:
Hexadecimal Literals

\[ \text{[\_charset\_name]} \text{X'val'} \text{[COLLATE collation\_name]} \]

Examples:

```
SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```

The examples use \text{X'val'} notation, but \text{0xval} notation permits introducers as well. For information about introducers, see Section 10.3.8, "Character Set Introducers".

In numeric contexts, MySQL treats a hexadecimal literal like a \text{BIGINT} (64-bit integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using \text{CAST(... AS UNSIGNED)}. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mymysql> SET @v2 = X'41'+0;
mymysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mymysql> SELECT @v1, @v2, @v3;
+------+------+------+
| @v1  | @v2  | @v3  |
| A    |   65 |   65 |
+------+------+------+
```

An empty hexadecimal value (\text{X''}) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
+--------------+-------------+
| CHARSET(X'') | LENGTH(X'') |
| binary       |           0 |
+--------------+-------------+
```

The \text{X'val'} notation is based on standard SQL. The \text{0x} notation is based on ODBC, for which hexadecimal strings are often used to supply values for \text{BLOB} columns.

To convert a string or a number to a string in hexadecimal format, use the \text{HEX()} function:

```
mysql> SELECT HEX('cat');
+------------+
| HEX('cat') |
| 636174     |
+------------+
```

```
mysql> SELECT X'636174';
+-----------+
| X'636174' |
| cat       |
+-----------+
```
For hexadecimal literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 8.0 and higher. To explicitly specify binary string context for hexadecimal literals, use a _binary introducer for at least one of the arguments:

```sql
mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+----------+----------+
| HEX(@v1) | HEX(@v2) |
+----------+----------+
| BCD      | 0BCD     |
+----------+----------+
```

The displayed result appears similar for both bit operations, but the result without _binary is a BIGINT value, whereas the result with _binary is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

### 9.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case sensitive and cannot be written as `0B`.

**Legal bit-value literals:**

- `b'01'`
- `B'01'`
- `0B01`

**Illegal bit-value literals:**

- `b'2'` (2 is not a binary digit)
- `0B01` (0B must be written as 0b)

By default, a bit-value literal is a binary string:

```sql
mysql> SELECT b'1000001', CHARSET(b'1000001');
+------------+---------------------+
| b'1000001' | CHARSET(b'1000001') |
| A          | binary              |
+------------+---------------------+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
+-----------+--------------------+
| 0b1100001 | CHARSET(0b1100001) |
| a         | binary             |
+-----------+--------------------+
```

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```sql
[_[charset_name] b'val' [COLLATE collation_name]]
```

**Examples:**

```sql
SELECT _latin1 b'1000001';
```
The examples use `b'value'` notation, but `0bvalue` notation permits introducers as well. For information about introducers, see Section 10.3.8, "Character Set Introducers".

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```sql
mysql> SET @v1 = b'1100001';
mymysql> SET @v2 = b'1100001'+0;
mymysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
mymysql> SELECT @v1, @v2, @v3;
+------+------+------+
| @v1  | @v2  | @v3  |
| a    |   97 |   97 |
+------+------+------+
```

An empty bit value (`b''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```sql
mysql> SELECT CHARSET(b''), LENGTH(b'');
+--------------+-------------+
| CHARSET(b'') | LENGTH(b'') |
| binary       |           0 |
+--------------+-------------+
mysql> SELECT b''+0;
+-------+
| b''+0 |
|     0 |
+-------+
```

Bit-value notation is convenient for specifying values to be assigned to `BIT` columns:

```sql
mysql> CREATE TABLE t (b BIT(8));
mymysql> INSERT INTO t SET b = b'11111111';
mymysql> INSERT INTO t SET b = b'1010';
mymysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as `BIN()` or `HEX()`. High-order 0 digits are not displayed in the converted value:

```sql
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
+--------+----------+--------+--------+
| b+0    | BIN(b)   | OCT(b) | HEX(b) |
| 255    | 11111111 | 377    | FF     |
| 10     | 1010     | 12     | A      |
| 5      | 101      | 5      | 5      |
+--------+----------+--------+--------+
```

For bit literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 8.0 and higher. To explicitly specify binary string context for bit literals, use a `_binary` introducer for at least one of the arguments:
The displayed result appears similar for both bit operations, but the result without _binary is a BIGINT value, whereas the result with _binary is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

9.1.6 Boolean Literals

The constants TRUE and FALSE evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0

9.1.7 NULL Values

The NULL value means "no data." NULL can be written in any lettercase.

Be aware that the NULL value is different from values such as 0 for numeric types or the empty string for string types. For more information, see Section B.6.4.3, "Problems with NULL Values".

For text file import or export operations performed with LOAD DATA or SELECT ... INTO OUTFILE, NULL is represented by the \N sequence. See Section 13.2.7, "LOAD DATA Syntax".

For sorting with ORDER BY, NULL values sort before other values for ascending sorts, after other values for descending sorts.

9.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, resource group and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. Section 9.2.2, "Identifier Case Sensitivity", describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you must quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at Section 9.3, "Keywords and Reserved Words".

Identifiers are converted to Unicode internally. They may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z$_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF
  - Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
Schema Object Names

- ASCII: U+0001 .. U+007F
- Extended: U+0080 .. U+FFFF
- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.
- Identifiers may begin with a digit but unless quoted may not consist solely of digits.
- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (`):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the ANSI_QUOTES SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The ANSI_QUOTES mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in Section 5.1.11, “Server SQL Modes”.

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b that contains a column named `c`d:

```
mysql> CREATE TABLE `a``b` (`c``d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with Me or MeN, where M and N are integers. For example, avoid using 1e as an identifier, because an expression such as 1e+3 is ambiguous. Depending on context, it might be interpreted as the expression 1e + 3 or as the number 1e+3.

Be careful when using MD5() to produce table names because it can produce names in illegal or ambiguous formats such as those just described.
A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See Section 9.4, “User-Defined Variables”, for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

The following table describes the maximum length for each type of identifier.

<table>
<thead>
<tr>
<th>Identifier Type</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Table</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Column</td>
<td>64</td>
</tr>
<tr>
<td>Index</td>
<td>64</td>
</tr>
<tr>
<td>Constraint</td>
<td>64</td>
</tr>
<tr>
<td>Stored Program</td>
<td>64</td>
</tr>
<tr>
<td>View</td>
<td>64</td>
</tr>
<tr>
<td>Tablespace</td>
<td>64</td>
</tr>
<tr>
<td>Server</td>
<td>64</td>
</tr>
<tr>
<td>Log File Group</td>
<td>64</td>
</tr>
<tr>
<td>Alias</td>
<td>256 (see exception following table)</td>
</tr>
<tr>
<td>Compound Statement Label</td>
<td>16</td>
</tr>
<tr>
<td>User-Defined Variable</td>
<td>64</td>
</tr>
<tr>
<td>Resource Group</td>
<td>64</td>
</tr>
</tbody>
</table>

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns. As indicated earlier, the permissible Unicode characters are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted.

NDB Cluster imposes a maximum length of 63 characters for names of databases and tables. See Section 22.1.7.5, “Limits Associated with Database Objects in NDB Cluster”.

1587
9.2.1 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name `t1`:

```sql
CREATE TABLE t1 (i INT);
```

Because `t1` includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name `db1.t1`:

```sql
CREATE TABLE db1.t1 (i INT);
```

Because `db1.t1` includes a database qualifier `db1`, the statement creates `t1` in the database named `db1`, regardless of the default database. The qualifier must be specified if there is no default database. The qualifier may be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `\`my-table`\` . `\`my-column`\`, not `my-table.my-column`.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

```sql
CREATE DATABASE db1;
```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in `CREATE` statements:

```sql
CREATE TABLE mytable ...;
CREATE VIEW myview ...;
CREATE PROCEDURE myproc ...;
CREATE FUNCTION myfunc ...;
CREATE EVENT myevent ...;
CREATE TABLE mydb.mytable ...;
CREATE VIEW mydb.myview ...;
CREATE PROCEDURE mydb.myproc ...;
CREATE FUNCTION mydb.myfunc ...;
```
CREATE EVENT mydb.myevent ...;

- A trigger is associated with a table, so any qualifier applies to the table name:

CREATE TRIGGER mytrigger ... ON mytable ...;
CREATE TRIGGER mytrigger ... ON mydb.mytable ...;

- A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

<table>
<thead>
<tr>
<th>Column Reference</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>col_name</td>
<td>Column col_name from whichever table used in the statement contains a column of that name</td>
</tr>
<tr>
<td>tbl1_name.col_name</td>
<td>Column col_name from table tbl1_name of the default database</td>
</tr>
<tr>
<td>db_name.tbl1_name.col_name</td>
<td>Column col_name from table tbl1_name of the database db_name</td>
</tr>
</tbody>
</table>

In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in SELECT statements:

```sql
SELECT c1 FROM mytable
WHERE c2 > 100;

SELECT mytable.c1 FROM mytable
WHERE mytable.c2 > 100;

SELECT mydb.mytable.c1 FROM mydb.mytable
WHERE mydb.mytable.c2 > 100;
```

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column c1 occurs only in table t1, c2 only in t2, and c in both t1 and t2. Any unqualified reference to c is ambiguous in a statement that refers to both tables and must be qualified as t1.c or t2.c to indicate which table you mean:

```sql
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2
WHERE t2.c > 100;
```

Similarly, to retrieve from a table t in database db1 and from a table t in database db2 in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers are required only for column names that appear in both tables. Suppose that column c1 occurs only in table db1.t, c2 only in db2.t, and c in both db1.t and db2.t. In this case, c is ambiguous and must be qualified but c1 and c2 need not be:

```sql
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t
WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```sql
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2
WHERE t2.c > 100;
```

### 9.2.2 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See Section 1.8.1, “MySQL Extensions to Standard SQL”. The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

**Note**

Although database, table, and trigger names are not case sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, event, and resource group names are not case-sensitive on any platform, nor are column aliases.

However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
            WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable. `lower_case_table_names` can take the values shown in the following table. This variable does **not** affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On macOS, the default value is 2.

`lower_case_table_names` can only be configured when initializing the server. Changing the `lower_case_table_names` setting after the server is initialized is prohibited.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Table and database names are stored on disk using the lowercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. You should <em>not</em> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access MyISAM tablenames using different lettercases, index corruption may result.</td>
</tr>
<tr>
<td>1</td>
<td>Table names are stored in lowercase on disk and name comparisons are not case-sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.</td>
</tr>
</tbody>
</table>
Mapping of Identifiers to File Names

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Table and database names are stored on disk using the lettercase specified in the CREATE TABLE or CREATE DATABASE statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works only on file systems that are not case-sensitive! InnoDB table names and view names are stored in lowercase, as for lower_case_table_names=1.</td>
</tr>
</tbody>
</table>

If you are using MySQL on only one platform, you do not normally have to use a lower_case_table_names setting other than the default. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named my_table and MY_TABLE, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use lower_case_table_names=1 on all systems. The main disadvantage with this is that when you use SHOW TABLES or SHOW DATABASES, you do not see the names in their original lettercase.
- Use lower_case_table_names=0 on Unix and lower_case_table_names=2 on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

**Exception:** If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should use lower_case_table_names=1 on all platforms to force names to be converted to lowercase.

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with PREPARE, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of INFORMATION_SCHEMA tables. For more information, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

### 9.2.3 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and depending upon the storage engine, each table may be represented by one or more files in the appropriate database directory.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the database directory, or the information may be stored in a separate file. InnoDB data is stored in the InnoDB data files. If you are using tablespaces with InnoDB, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (X'00'). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (a..zA..Z), digits (0..9) and underscore (_) are encoded as is. Consequently, their case sensitivity directly depends on file system features.
• All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

<table>
<thead>
<tr>
<th>Code Range</th>
<th>Pattern</th>
<th>Number</th>
<th>Used</th>
<th>Unused</th>
<th>Blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>00C0..017F</td>
<td>[0..4][g..z]</td>
<td>5*20 = 100</td>
<td>97</td>
<td>3</td>
<td>Latin-1 Supplement + Latin Extended-A</td>
</tr>
<tr>
<td>0370..03FF</td>
<td>[5..9][g..z]</td>
<td>5*20 = 100</td>
<td>88</td>
<td>12</td>
<td>Greek and Coptic</td>
</tr>
<tr>
<td>0400..052F</td>
<td>[g..z][0..6]</td>
<td>20*7 = 140</td>
<td>137</td>
<td>3</td>
<td>Cyrillic + Cyrillic Supplement</td>
</tr>
<tr>
<td>0530..058F</td>
<td>[g..z][7..8]</td>
<td>20*2 = 40</td>
<td>38</td>
<td>2</td>
<td>Armenian</td>
</tr>
<tr>
<td>2160..217F</td>
<td>[g..z][9]</td>
<td>20*1 = 20</td>
<td>16</td>
<td>4</td>
<td>Number Forms</td>
</tr>
<tr>
<td>0180..02AF</td>
<td>[a..k][g..z]</td>
<td>20*11 = 220</td>
<td>203</td>
<td>17</td>
<td>Latin Extended-B + IPA Extensions</td>
</tr>
<tr>
<td>1E00..1EFF</td>
<td>[l..r][g..z]</td>
<td>20*7 = 140</td>
<td>136</td>
<td>4</td>
<td>Latin Extended Additional</td>
</tr>
<tr>
<td>1F00..1FFF</td>
<td>[s..z][g..z]</td>
<td>20*8 = 160</td>
<td>144</td>
<td>16</td>
<td>Greek Extended</td>
</tr>
<tr>
<td>.... ....</td>
<td>[a..f][g..z]</td>
<td>6*20 = 120</td>
<td>0</td>
<td>120</td>
<td>RESERVED</td>
</tr>
<tr>
<td>24B6..24E9</td>
<td>[@][a..z]</td>
<td>26</td>
<td>26</td>
<td>0</td>
<td>Enclosed Alphanumerics</td>
</tr>
<tr>
<td>FF21..FF5A</td>
<td>[@][a..z][@]</td>
<td>26</td>
<td>26</td>
<td>0</td>
<td>Halfwidth and Fullwidth forms</td>
</tr>
</tbody>
</table>

One of the bytes in the sequence encodes lettercase. For example: \texttt{LATIN CAPITAL LETTER A WITH GRAVE} is encoded as \texttt{@0G}, whereas \texttt{LATIN SMALL LETTER A WITH GRAVE} is encoded as \texttt{@0g}. Here the third byte (G or g) indicates lettercase. (On a case-insensitive file system, both letters will be treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

• All nonletter characters except underscore (_), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits \texttt{a..f}:

\begin{align*}
\texttt{0x003F} & \rightarrow \texttt{@03F} \\
\texttt{0xFFFF} & \rightarrow \texttt{@fff}
\end{align*}

The hexadecimal values correspond to character values in the \texttt{ucs2} double-byte character set.

On Windows, some names such as \texttt{nul}, \texttt{prn}, and \texttt{aux} are encoded by appending \texttt{@@@} to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

### 9.2.4 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.
• **Built-In Function Name Parsing**

• **Function Name Resolution**

**Built-In Function Name Parsing**

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

• To use the name as a function call in an expression, there must be no whitespace between the name and the following ( parenthesis character.

• Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The `sql/lex.h` source file lists the names of these special functions for which following whitespace determines their interpretation: names defined by the `SYM_FN()` macro in the `symbols[]` array.

The following list names the functions in MySQL 8.0 that are affected by the `IGNORE_SPACE` setting and listed as special in the `sql/lex.h` source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

• `ADDDATE`
• `BIT_AND`
• `BIT_OR`
• `BIT_XOR`
• `CAST`
• `COUNT`
• `CURDATE`
• `CURTIME`
• `DATE_ADD`
• DATE_SUB
• EXTRACT
• GROUP_CONCAT
• MAX
• MID
• MIN
• NOW
• POSITION
• SESSION_USER
• STD
• STDDEV
• STDDEV_POP
• STDDEV_SAMP
• SUBDATE
• SUBSTR
• SUBSTRING
• SUM
• SYSDATE
• SYSTEM_USER
• TRIM
• VARIANCE
• VAR_POP
• VAR_SAMP

For functions not listed as special in sql/lex.h, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. ASCII is one such name. However, for these nonaffected function names, interpretation may vary in expression context: func_name () is interpreted as a built-in function if there is one with the given name; if not, func_name () is interpreted as a user-defined function or stored function if one exists with that name.

The IGNORE_SPACE SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

• With IGNORE_SPACE disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following
the name or write it as a quoted identifier (or both):

CREATE TABLE  count  (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);

• With IGNORE_SPACE enabled, the parser loosens the requirement that there be no whitespace between
the function name and the following parenthesis. This provides more flexibility in writing function calls.
For example, either of the following function calls are legal:

SELECT COUNT(*) FROM mytable;
SELECT COUNT ( *) FROM mytable;

However, enabling IGNORE_SPACE also has the side effect that the parser treats the affected function
names as reserved words (see Section 9.3, “Keywords and Reserved Words”). This means that a space
following the name no longer signifies its use as an identifier. The name can be used in function calls
with or without following whitespace, but causes a syntax error in nonexpression context unless it is
quoted. For example, with IGNORE_SPACE enabled, both of the following statements fail with a syntax
error because the parser interprets count as a reserved word:

CREATE TABLE count(i INT);
CREATE TABLE count (i INT);

To use the function name in nonexpression context, write it as a quoted identifier:

CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);

To enable the IGNORE_SPACE SQL mode, use this statement:

SET sql_mode = 'IGNORE_SPACE';

IGNORE_SPACE is also enabled by certain other composite modes such as ANSI that include it in their
value:

SET sql_mode = 'ANSI';

Check Section 5.1.11, “Server SQL Modes”, to see which composite modes enable IGNORE_SPACE.

To minimize the dependency of SQL code on the IGNORE_SPACE setting, use these guidelines:

• Avoid creating UDFs or stored functions that have the same name as a built-in function.

• Avoid using function names in nonexpression context. For example, these statements use count (one
of the affected function names affected by IGNORE_SPACE), so they fail with or without whitespace
following the name if IGNORE_SPACE is enabled:

CREATE TABLE count(i INT);
Keywords and Reserved Words

Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and user-defined functions

  An error occurs if you try to create a UDF with the same name as a built-in function.

- Built-in functions and stored functions

  It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

- User-defined functions and stored functions

  User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF and `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. Then modify any affected code to use the new name.

- If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in Section 9.2, “Schema Object Names”:

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```
BEGIN and END are keywords but not reserved, so their use as identifiers does not require quoting. INTERVAL is a reserved keyword and must be quoted to be used as an identifier:

```sql
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```sql
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, COUNT is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following ( character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see Section 9.2.4, “Function Name Parsing and Resolution”.

The INFORMATION_SCHEMA.KEYWORDS table lists the words considered keywords by MySQL and indicates whether they are reserved. See Section 25.14, “The INFORMATION_SCHEMA KEYWORDS Table”.

- MySQL 8.0 Keywords and Reserved Words
- MySQL 8.0 New Keywords and Reserved Words
- MySQL 8.0 Removed Keywords and Reserved Words

**MySQL 8.0 Keywords and Reserved Words**

The following list shows the keywords and reserved words in MySQL 8.0, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, _FILENAME is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, GROUP). A few are reserved because MySQL needs them and uses a yacc parser.

| A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z |

9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumerical characters, .-_, and $. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var`).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema `user_variables_by_thread` table can see all user variables for all sessions.) All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive. Names have a maximum length of 64 characters.

One way to set a user-defined variable is by issuing a `SET` statement:

```sql
SET @var_name = expr [, @var_name = expr] ... 
```

For `SET`, either `= ` or `:= ` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the JSON data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```sql
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
```

```sql
mysql> SELECT @v1, @v2, @v3;
```

```
+------+------+------+
|   A  |   65 |   65 |
+------+------+------+
```
If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

Previous releases of MySQL made it possible to assign a value to a user variable in statements other than `SET`. This functionality is supported in MySQL 8.0 for backward compatibility but is subject to removal in a future release of MySQL.

When making an assignment in this way, you must use `:=` as the assignment operator; `=` is treated as the comparison operator in statements other than `SET`.

The order of evaluation for expressions involving user variables is undefined. For example, there is no guarantee that `SELECT @a, @a:=@a+1` evaluates `@a` first and then performs the assignment.

In addition, the default result type of a variable is based on its type at the beginning of the statement. This may have unintended effects if a variable holds a value of one type at the beginning of a statement in which it is also assigned a new value of a different type.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `'` to define its type before you use it.

`HAVING`, `GROUP BY`, and `ORDER BY`, when referring to a variable that is assigned a value in the select expression list do not work as expected because the expression is evaluated on the client and thus can use stale column values from a previous row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as `SELECT`. This is true even if the variable is quoted, as shown in the following example:

```sql
mysql> SELECT c1 FROM t;
+----+
| c1 |
+----+
| 0  |
+----+
| 1  |
+----+
2 rows in set (0.00 sec)
mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @col FROM t;
+------+
|      |
+------+
```
User-Defined Variables

<table>
<thead>
<tr>
<th>@col</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;

+------+
| @col |
+------+
| `c1` |

1 row in set (0.00 sec)

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;

+----+
| c1  |
+----+
| 0   |
| 1   |

2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```php
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");
    if( mysqli_connect_errno() )
        die( "Connection failed: %s\n", mysqli_connect_error() );
    $col = "c1";
    $query = "SELECT $col FROM t";
    $result = $mysqli->query($query);
```
Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

9.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- Expression Syntax
- Expression Term Notes
- Temporal Intervals

Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the sql/sql_yacc.yy file of MySQL source distributions. For additional information about some of the expression terms, see Expression Term Notes.

```plaintext
expr:
    expr OR expr
    | expr || expr
    | expr XOR expr
    | expr AND expr
    | expr && expr
    | NOT expr
    | ! expr
    | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
    | boolean_primary

boolean_primary:
    boolean_primary IS [NOT] NULL
    | boolean_primary <=> predicate
    | boolean_primary comparison_operator predicate
    | boolean_primary comparison_operator {ALL | ANY} (subquery)
    | predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
    bit_expr [NOT] IN (subquery)
    | bit_expr [NOT] IN (expr [, expr] ...)
    | bit_expr [NOT] BETWEEN bit_expr AND predicate
    | bit_expr SOUNDS LIKE bit_expr
    | bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
    | bit_expr [NOT] REGEXP bit_expr
    | bit_expr

bit_expr:
    bit_expr | bit_expr
    | bit_expr & bit_expr
    | bit_expr << bit_expr
```
For operator precedence, see Section 12.3.1, “Operator Precedence”. The precedence and meaning of some operators depends on the SQL mode:

- By default, || is a logical OR operator. With PIPES_AS_CONCAT enabled, || is string concatenation, with a precedence between ^ and the unary operators.

- By default, ! has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, ! and NOT have the same precedence.

See Section 5.1.11, “Server SQL Modes”.

**Expression Term Notes**

For literal value syntax, see Section 9.1, “Literal Values”.

For identifier syntax, see Section 9.2, “Schema Object Names”.

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: Section 9.4, “User-Defined Variables”

- System variables: Section 5.1.9, “Using System Variables”

- Stored program local variables: Section 13.6.4.1, “Local Variable DECLARE Syntax”

- Stored program parameters: Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Syntax”
**Temporal Intervals**

`param_marker` is `?` as used in prepared statements for placeholders. See Section 13.5.1, “PREPARE Syntax”.

(subquery) indicates a subquery that returns a single value; that is, a scalar subquery. See Section 13.2.11.1, “The Subquery as Scalar Operand”.

(identifier expr) is ODBC escape syntax and is accepted for ODBC compatibility. The value is expr. The ( and ) curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

match_expr indicates a MATCH expression. See Section 12.9, “Full-Text Search Functions”.

case_expr indicates a CASE expression. See Section 12.4, “Control Flow Functions”.

interval_expr represents a temporal interval. See Temporal Intervals.

## Temporal Intervals

interval_expr in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

expr represents a quantity. unit represents the unit for interpreting the quantity; it is a specifier such as HOUR, DAY, or WEEK. The INTERVAL keyword and the unit specifier are not case sensitive.

The following table shows the expected form of the expr argument for each unit value.

<table>
<thead>
<tr>
<th>unit Value</th>
<th>Expected expr Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>MICROSECOND</td>
<td>MICROSECONDS</td>
</tr>
<tr>
<td>SECOND</td>
<td>SECONDS</td>
</tr>
<tr>
<td>MINUTE</td>
<td>MINUTES</td>
</tr>
<tr>
<td>HOUR</td>
<td>HOURS</td>
</tr>
<tr>
<td>DAY</td>
<td>DAYS</td>
</tr>
<tr>
<td>WEEK</td>
<td>WEEKS</td>
</tr>
<tr>
<td>MONTH</td>
<td>MONTHS</td>
</tr>
<tr>
<td>QUARTER</td>
<td>QUARTERS</td>
</tr>
<tr>
<td>YEAR</td>
<td>YEARS</td>
</tr>
<tr>
<td>SECOND_MICROSECOND</td>
<td>'SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_MICROSECOND</td>
<td>'MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_SECOND</td>
<td>'MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MICROSECOND</td>
<td>'HOURS:MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>HOUR_SECOND</td>
<td>'HOURS:MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MINUTE</td>
<td>'HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_MICROSECOND</td>
<td>'DAYS.HOURS:MINUTES.MICROSECONDS'</td>
</tr>
<tr>
<td>DAY_SECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS'</td>
</tr>
</tbody>
</table>
Temporal Intervals

<table>
<thead>
<tr>
<th>unit</th>
<th>Value</th>
<th>Expected expr Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY_MINUTE</td>
<td></td>
<td>'DAYS HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_HOUR</td>
<td></td>
<td>'DAYS HOURS'</td>
</tr>
<tr>
<td>YEAR_MONTH</td>
<td></td>
<td>'YEARS-MONTHS'</td>
</tr>
</tbody>
</table>

MySQL permits any punctuation delimiter in the `expr` format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as `DATE_ADD()` and `DATE_SUB()`:

```sql
SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
-> '2018-05-02'
SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
-> '2017-05-01'
SELECT DATE_ADD('2018-12-31 23:59:59', INTERVAL 1 SECOND);
-> '2021-01-01 23:59:59'
SELECT DATE_ADD('2020-12-31 23:59:59', INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
SELECT DATE_ADD('2019-12-31 23:59:59', INTERVAL 1 SECOND);
-> '2021-01-01 23:59:59'
SELECT DATE_ADD('2019-12-31 23:59:59', INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
SELECT DATE_SUB('2025-01-01 00:00:00', INTERVAL '1 1:1:1' SECOND);  
-> '2024-12-30 22:58:59'
SELECT DATE_ADD('2019-12-31 23:59:59', INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

Temporal arithmetic also can be performed in expressions using `INTERVAL` together with the `+` or `-` operator:

```sql
date + INTERVAL expr unit
date - INTERVAL expr unit
```

`INTERVAL expr unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `-` operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```sql
SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
SELECT '2025-01-01' - INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'
```

The `EXTRACT()` function uses the same kinds of `unit` specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic:

```sql
SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
```
Temporal intervals can be used in `CREATE EVENT` statements:

```sql
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

`expr` is treated as a string, so be careful if you specify a non-string value with `INTERVAL`. For example, with an interval specifier of `HOUR_MINUTE`, `'6/4'` is treated as 6 hours, four minutes, whereas `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```
mysql> SELECT '6/4', 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL '6/4' HOUR_MINUTE);
-> '2019-01-01 06:04:00'
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2019-01-04 12:20:00'
```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `'6/4'` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```
mysql> SELECT CAST('6/4' AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00', INTERVAL CAST('6/4' AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
-> '2023-01-02'
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
-> '2023-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
-> '2019-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2016-07-00'` or badly malformed dates:

```
mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
```

9.6 Comment Syntax

MySQL Server supports three comment styles:

- From a `#` character to the end of the line.
- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.8.2.4, "`--` as the Start of a Comment".
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```sql
mysql> SELECT 1+1;     # This comment continues to the end of line
mysql> SELECT 1+1;     -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1 +
   /*
   * this is a
   * multiple-line comment
   */
   1;
```

Nested comments are not supported, are deprecated, and will be removed in a future MySQL release. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```sql
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```sql
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```sql
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.)
Comments in this format, /*!12345 ... */, are not stored on the server. If this format is used to comment stored routines, the comments will not be retained on the server.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a + character following the /* comment opening sequence. Example:

```sql
SELECT /*+ BKA(t1) */ FROM ... ;
```

For more information, see Section 8.9.2, “Optimizer Hints”.

The use of short-form MySQL commands such as \C within multiple-line /* ... */ comments is not supported.

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see Section 10.5, “Configuring Application Character Set and Collation”, and Section 10.4, “Connection Character Sets and Collations”.

### 10.1 Character Sets and Collations in General

A **character set** is a set of symbols and encodings. A **collation** is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: A, B, a, b. We give each letter a number: A = 0, B = 1, a = 2, b = 3. The letter A is a symbol, the number 0 is the **encoding** for A, and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, A and B. The simplest way to do this is to look at the encodings: 0 for A and 1 for B. Because 0 is less than 1, we say A is less than B. What we’ve just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a **binary collation**.
But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters \(a\) and \(b\) as equivalent to \(A\) and \(B\); (2) then compare the encodings. We call this a \textit{case-insensitive} collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just \(A\) and \(B\) but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German \(Ö\)), and for multiple-character mappings (such as the rule that \(ō = Ḟ\) in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

### 10.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets, including several Unicode character sets. To display the available character sets, use the `INFORMATION_SCHEMA CHARACTER_SETS` table or the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see Section 10.10, “Supported Character Sets and Collations”.

```
mysql> SHOW CHARACTER SET;
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
| big5     | Big5 Traditional Chinese        | big5_chinese_ci     | 2      |
| binary   | Binary pseudo charset           | binary              | 1      |
| latin1   | cp1252 West European            | latin1_swedish_ci   | 1      |
| ...      | ...                             | ...                 | ...    |
| utf8     | UTF-8 Unicode                   | utf8_general_ci     | 3      |
| utf8mb4  | UTF-8 Unicode                   | utf8mb4_0900_ai_ci  | 4      |
+----------+---------------------------------+---------------------+--------+
```

By default, the `SHOW CHARACTER SET` statement displays all available character sets. It takes an optional \texttt{LIKE} or \texttt{WHERE} clause that indicates which character set names to match. The following example shows some of the Unicode character sets (those based on Unicode Transformation Format):

```
mysql> SHOW CHARACTER SET LIKE 'utf%';
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
| utf16    | UTF-16 Unicode                  | utf16_general_ci    | 4      |
| utf16le  | UTF-16LE Unicode                | utf16le_general_ci  | 4      |
| utf32    | UTF-32 Unicode                  | utf32_general_ci    | 4      |
| utf8     | UTF-8 Unicode                   | utf8_general_ci     | 3      |
| utf8mb4  | UTF-8 Unicode                   | utf8mb4_0900_ai_ci  | 4      |
+----------+---------------------------------+---------------------+--------+
```
A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the INFORMATION_SCHEMA COLLATIONS table or the SHOW COLLATION statement.

By default, the SHOW COLLATION statement displays all available collations. It takes an optional LIKE or WHERE clause that indicates which collation names to display. For example, to see the collations for the default character set, utf8mb4, use this statement:

```
mysql> SHOW COLLATION WHERE Charset = 'utf8mb4';
```

</tbody>
</table>

For more information about those collations, see Section 10.10.1, “Unicode Character Sets”.

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a default collation. For example, the default collations for utf8mb4 and latin1 are utf8mb4_0900_ai_ci and latin1_swedish_ci, respectively. The INFORMATION_SCHEMA CHARACTER SETS table and the SHOW CHARACTER SET statement indicate the default collation for each character set. The INFORMATION_SCHEMA COLLATIONS table and the SHOW COLLATION statement have a column that indicates for each collation whether it is the default for its character set (Yes if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see Section 10.3.1, “Collation Naming Conventions”.

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 10.2.1 Character Set Repertoire

The repertoire of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only characters in the Unicode range U+0000 to U+007F.
- **UNICODE**: The expression can contain characters in the Unicode range U+0000 to U+10FFFF. This includes characters in the Basic Multilingual Plane (BMP) range (U+0000 to U+FFFF) and supplementary characters outside the BMP range (U+10000 to U+10FFFF).

The ASCII range is a subset of UNICODE range, so a string with ASCII repertoire can be converted safely without loss of information to the character set of any string with UNICODE repertoire or to a character set that is a superset of ASCII. (All MySQL character sets are supersets of ASCII with the exception of swe7, which reuses some punctuation characters for Swedish accented characters.) The use of repertoire
enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error.

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

• The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

```sql
SET NAMES utf8; SELECT 'abc';
SELECT _utf8'def';
SELECT N'MySQL';
```

Although the character set is `utf8` in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is `ASCII` rather than `UNICODE`.

• A column having the `ascii` character set has `ASCII` repertoire because of its character set. In the following table, `c1` has `ASCII` repertoire:

```sql
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```sql
CREATE TABLE t1 {
  c1 CHAR(1) CHARACTER SET latin1,
  c2 CHAR(1) CHARACTER SET ascii
};
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset (`ascii` to `latin1`) conversion can occur and a result is returned:

```
+---------------+
| CONCAT(c1,c2) |
+---------------+
| ab            |
```

• Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8'abc')` has `ASCII` repertoire because its argument has `ASCII` repertoire.

• For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is `ASCII` if `character_set_connection` is `ascii`, and `UNICODE` otherwise:

```sql
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;

Without repertoire, this error occurs:

ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE) and (latin1_swedish_ci,IMPLICIT) for operation 'concat'

With repertoire, a result is returned:

+-------------------------+
<table>
<thead>
<tr>
<th>CONCAT(FORMAT(a, 4), b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000b</td>
</tr>
</tbody>
</table>
+-------------------------+

• Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire (UNICODE is wider than ASCII). Consider the following CONCAT() calls:

CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')

For the first call, the repertoire is ASCII because both arguments are within the range of the ascii character set. For the second call, the repertoire is UNICODE because the second argument is outside the ascii character set range.

• The repertoire for function return values is determined based only on the repertoire of the arguments that affect the result's character set and collation.

IF(column1 < column2, 'smaller', 'greater')

The result repertoire is ASCII because the two string arguments (the second argument and the third argument) both have ASCII repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

10.2.2 UTF-8 for Metadata

Metadata is “the data about the data.” Anything that describes the database—as opposed to being the contents of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from SHOW are metadata. This is also true of the contents of tables in INFORMATION_SCHEMA because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

• All metadata must be in the same character set. Otherwise, neither the SHOW statements nor SELECT statements for tables in INFORMATION_SCHEMA would work properly because different rows in the same column of the results of these operations would be in different character sets.

• Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.
The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```sql
mysql> SHOW VARIABLES LIKE 'character_set_system';
+----------------------+-------+
| Variable_name         | Value |
+----------------------+-------+
| character_set_system  | utf8  |
+----------------------+-------+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t;`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `utf8mb4`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See Section 10.4, “Connection Character Sets and Collations”.) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```sql
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```sql
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a "subset" of Unicode. Because it is a well-known principle that "what applies to a superset can apply to a subset," we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 10.8.4, “Collation Coercibility in Expressions”.

### 10.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.
**CHARACTER SET** is used in clauses that specify a character set. **CHARSET** can be used as a synonym for **CHARACTER SET**.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the **utf8mb4** Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8mb4';
```

For more information about character set-related issues in client/server communication, see Section 10.4, “Connection Character Sets and Collations”.

### 10.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, **utf8mb4_general_ci** and **latin1_swedish_ci** are collations for the **utf8mb4** and **latin1** character sets, respectively. The **binary** character set has a single collation, also named **binary**, with no suffixes.

- A language-specific collation includes a locale code or language name. For example, **utf8mb4_tr_0900_ai_ci** and **utf8mb4_hu_0900_ai_ci** sort characters for the **utf8mb4** character set using the rules of Turkish and Hungarian, respectively. **utf8mb4_turkish_ci** and **utf8mb4_hungarian_ci** are similar but based on a less recent version of the Unicode Collation Algorithm.

- Collation suffixes indicate whether a collation is case and accent sensitive, or binary. The following table shows the suffixes used to indicate these characteristics.

#### Table 10.1 Collation Case/Accent Sensitivity Suffixes

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_ai</td>
<td>Accent insensitive</td>
</tr>
<tr>
<td>_as</td>
<td>Accent sensitive</td>
</tr>
<tr>
<td>_ci</td>
<td>Case insensitive</td>
</tr>
<tr>
<td>_cs</td>
<td>case-sensitive</td>
</tr>
<tr>
<td>_ks</td>
<td>Kana sensitive</td>
</tr>
<tr>
<td>_bin</td>
<td>Binary</td>
</tr>
</tbody>
</table>

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain _ai or _as, _ci in the name implies _ai and _cs in the name implies _as. For example, **latin1_general_ci** is explicitly case insensitive and implicitly accent insensitive, **latin1_general_cs** is explicitly case sensitive and implicitly accent sensitive, and **utf8mb4_0900_ai_ci** is explicitly case and accent insensitive.

For Japanese collations, the _ks suffix indicates that a collation is kana sensitive; that is, it distinguishes Katakana characters from Hiragana characters. Japanese collations without the _ks suffix are not kana sensitive and treat Katakana and Hiragana characters equal for sorting.

For the **binary** collation of the **binary** character set, comparisons are based on numeric byte values. For the _bin collation of a nonbinary character set, comparisons are based on numeric character code
values, which differ from byte values for multibyte characters. For more information, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

• For Unicode character sets, collation names may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:

  • utf8mb4_0900_ai_ci is based on UCA 9.0.0 weight keys (http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt).

  • utf8mb4_unicode_520_ci is based on UCA 5.2.0 weight keys (http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt).

  • utf8mb4_unicode_ci (with no version named) is based on UCA 4.0.0 weight keys (http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt).

• For Unicode character sets, the xxx_general_mysql500_ci collations preserve the pre-5.1.24 ordering of the original xxx_general_ci collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start mysqld. You can use --character-set-server for the character set. Along with it, you can add --collation-server for the collation. If you don't specify a character set, that is the same as saying --character-set-server=utf8mb4. If you specify only a character set (for example, utf8mb4) but not a collation, that is the same as saying --character-set-server=utf8mb4 --collation-server=utf8mb4_0900_ai_ci because utf8mb4_0900_ai_ci is the default collation for utf8mb4. Therefore, the following three commands all have the same effect:

```
mysqld
mysqld --character-set-server=utf8mb4
mysqld --character-set-server=utf8mb4 \
  --collation-server=utf8mb4_0900_ai_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the DEFAULT_CHARSET and DEFAULT_COLLATION options for CMake. For example:

```
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```
cmake . -DDEFAULT_CHARSET=latin1 \
  -DDEFAULT_COLLATION=latin1_german1_ci
```

Both mysqld and CMake verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in CREATE DATABASE statements. They have no other purpose.
The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

### 10.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

```
ALTER DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Database options are stored in the data dictionary and can be examined by checking the `INFORMATION_SCHEMA.SCHEMATA` table.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
SELECT @@character_set_database, @@collation_database;
```
Alternatively, to display the values without changing the default database:

```sql
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.

- For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.

- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or a `COLLATE` attribute. To override this, provide `CHARACTER SET` and `COLLATE` explicitly.

### 10.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```sql
CREATE TABLE tbl_name (column_list)
    [[DEFAULT] CHARACTER SET charset_name]
    [COLLATE collation_name]]

ALTER TABLE tbl_name
    [[DEFAULT] CHARACTER SET charset_name]
    [COLLATE collation_name]]
```

Example:

```sql
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.
10.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type CHAR, VARCHAR, a TEXT type, or any synonym) has a column character set and a column collation. Column definition syntax for CREATE TABLE and ALTER TABLE has optional clauses for specifying the column character set and collation:

```
col_name (CHAR | VARCHAR | TEXT) (col_length)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

These clauses can also be used for ENUM and SET columns:

```
col_name (ENUM | SET) (val_list)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
  col1 VARCHAR(5) CHARACTER SET latin1
  COLLATE latin1_german1_ci
);
ALTER TABLE t1 MODIFY
  col1 VARCHAR(5) CHARACTER SET latin1
  COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both CHARACTER SET charset_name and COLLATE collation_name are specified, character set charset_name and collation collation_name are used.

```
CREATE TABLE t1
(
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set utf8 and collation utf8_unicode_ci.

- If CHARACTER SET charset_name is specified without COLLATE, character set charset_name and its default collation are used.

```
CREATE TABLE t1
(
  col1 CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set utf8 and the default collation for utf8, which is utf8_general_ci. To see the default collation for each character set, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA CHARACTER_SETS table.

- If COLLATE collation_name is specified without CHARACTER SET, the character set associated with collation_name and collation collation_name are used.
CREATE TABLE t1
(
  col1 CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;

The collation is specified for the column, but the character set is not. The column has collation utf8_polish_ci and the character set is the one associated with the collation, which is utf8.

- Otherwise (neither CHARACTER SET nor COLLATE is specified), the table character set and collation are used.

CREATE TABLE t1
(
  col1 CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set latin1 and collation latin1_bin.

The CHARACTER SET and COLLATE clauses are standard SQL.

If you use ALTER TABLE to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

### 10.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `_charset_name`.” An introducer does not change the string to the introducer character set like CONVERT() would do. It does not change the string value, although padding may occur. The introducer is just a signal. See Section 10.3.8, “Character Set Introducers”.

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;
```

Character set introducers and the COLLATE clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both `_charset_name` and COLLATE `collation_name` are specified, character set `_charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `_charset_name`.
• If \_charset\_name is specified but COLLATE is not specified, character set \ charset\_name and its default collation are used. To see the default collation for each character set, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA CHARACTER_SETS table.

• If \_charset\_name is not specified but COLLATE collation\_name is specified, the connection default character set given by the character_set_connection system variable and collation collation\_name are used. collation\_name must be a permitted collation for the connection default character set.

• Otherwise (neither \_charset\_name nor COLLATE collation\_name is specified), the connection default character set and collation given by the character_set_connection and collation_connection system variables are used.

Examples:

• A nonbinary string with latin1 character set and latin1\_german1\_ci collation:

```sql
SELECT \_latin1'Müller' COLLATE latin1\_german1\_ci;
```

• A nonbinary string with utf8mb4 character set and its default collation (that is, utf8mb4\_general\_ci):

```sql
SELECT \_utf8mb4'Müller';
```

• A binary string with binary character set and its default collation (that is, binary):

```sql
SELECT \_binary'Müller';
```

• A nonbinary string with the connection default character set and utf8mb4\_general\_ci collation (fails if the connection character set is not utf8mb4):

```sql
SELECT 'Müller' COLLATE utf8mb4\_general\_ci;
```

• A string with the connection default character set and collation:

```sql
SELECT 'Müller';
```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by character_set_connection.

The following examples show that escape processing occurs using character_set_connection even in the presence of an introducer. The examples use SET NAMES (which changes character_set_connection, as discussed in Section 10.4, “Connection Character Sets and Collations”), and display the resulting strings using the HEX() function so that the exact string contents can be seen.

Example 1:

```sql
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+------------+-----------------+
| HEX('à\n')  | HEX(_sjis'à\n')  |
+------------+-----------------+
| E00A       | E00A            |
+------------+-----------------+
```
Here, à (hexadecimal value \x0E) is followed by \n, the escape sequence for newline. The escape sequence is interpreted using the character_set_connection value of latin1 to produce a literal newline (hexadecimal value \x0A). This happens even for the second string. That is, the _sjis introducer does not affect the parser’s escape processing.

Example 2:

```sql
mysql> SET NAMES sjis;
mysql> SELECT HEX('à
'), HEX(_latin1'à
');
```

| HEX('à
')  | HEX(_latin1'à
')  |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>E05C6E</td>
<td>E05C6E</td>
</tr>
</tbody>
</table>

Here, character_set_connection is sjis, a character set in which the sequence of à followed by \ (hexadecimal values \x05 and \x5C) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single sjis character, and the \ is not interpreted as an escape character. The following n (hexadecimal value \x06) is not interpreted as part of an escape sequence. This is true even for the second string; the _latin1 introducer does not affect escape processing.

### 10.3.7 The National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

- `CHAR(10) CHARACTER SET utf8`
- `NATIONAL CHARACTER(10)`
- `NCHAR(10)`

As are these:

- `VARCHAR(10) CHARACTER SET utf8`
- `NATIONAL VARCHAR(10)`
- `NVARCHAR(10)`
- `NCHAR VARCHAR(10)`
- `NATIONAL CHARACTER VARYING(10)`
- `NATIONAL CHAR VARYING(10)`

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

- `SELECT N'some text';`
- `SELECT n'some text';`
- `SELECT _utf8'some text';`

### 10.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_[charset_name]] literal [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set _charset_name.” An introducer does not change the string to the introducer character
Character Set Introducers

set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

Examples:

```sql
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;
SELECT _latin1 X'4D7953514C';
SELECT _utf8mb4 0x4D7953514C COLLATE utf8mb4_danish_ci;
SELECT _latin1 b'1000001';
SELECT _utf8mb4 0b1000001 COLLATE utf8mb4_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but normally unnecessary. `_binary` may be useful to preserve a hexadecimal or bit literal as a binary string in contexts for which the literal is otherwise treated as a number. For example, bit operations permit numeric or binary string arguments in MySQL 8.0 and higher, but treat hexadecimal and bit literals as numbers by default. To explicitly specify binary string context for such literals, use a `_binary` introducer for at least one of the arguments:

```sql
mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
```

<table>
<thead>
<tr>
<th>HEX(@v1)</th>
<th>HEX(@v2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BCD</td>
<td>0BCD</td>
</tr>
</tbody>
</table>

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both `_charset_name` and `COLLATE` `collation_name` are specified, character set `_charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `_charset_name`.

- If `_charset_name` is specified but `COLLATE` is not specified, character set `_charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If `_charset_name` is not specified but `COLLATE` `collation_name` is specified:

  - For a character string literal, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
Examples of Character Set and Collation Assignment

• For a hexadecimal literal or bit-value literal, the only permitted collation is `binary` because these types of literals are binary strings by default.

• Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified):

  • For a character string literal, the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

  • For a hexadecimal literal or bit-value literal, the character set and collation are `binary`.

Examples:

• Nonbinary strings with `latin1` character set and `latin1_german1_ci` collation:

  ```sql
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;
  SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
  ```

• Nonbinary strings with `utf8mb4` character set and its default collation (that is, `utf8mb4_0900_ai_ci`):

  ```sql
  SELECT _utf8mb4'Müller';
  SELECT _utf8mb4 X'0A0D';
  SELECT _utf8mb4 b'0110';
  ```

• Binary strings with `binary` character set and its default collation (that is, `binary`):

  ```sql
  SELECT _binary'Müller';
  SELECT X'0A0D';
  SELECT b'0110';
  ```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

• A nonbinary string with the connection default character set and `utf8mb4_general_ci` collation (fails if the connection character set is not `utf8mb4`):

  ```sql
  SELECT 'Müller' COLLATE utf8mb4_general_ci;
  ```

This construction (`COLLATE` only) does not work for hexadecimal literals or bit literals because their character set is `binary` no matter the connection character set, and `binary` is not compatible with the `utf8mb4_general_ci` collation. The only permitted `COLLATE` clause in the absence of an introducer is `COLLATE binary`.

• A string with the connection default character set and collation:

  ```sql
  SELECT 'Müller';
  ```

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`. For additional discussion and examples, see Section 10.3.6, “Character String Literal Character Set and Collation”.

10.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.
Example 1: Table and Column Definition

```sql
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

Example 2: Table and Column Definition

```sql
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table and Column Definition

```sql
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```sql
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We’re also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

### 10.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```sql
CREATE TABLE t1 (f1 CHAR(0) UNICODE);
CREATE TABLE t1 (f1 CHAR(0) CHARACTER SET ucs2);
```

### 10.4 Connection Character Sets and Collations
A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- Connection Character Set and Collation System Variables
- Impermissible Client Character Sets
- Client Program Connection Character Set Configuration
- SQL Statements for Connection Character Set Configuration
- Connection Character Set Error Handling

### Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See Section 10.3.2, “Server Character Set and Collation”.

- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See Section 10.3.3, “Database Character Set and Collation”.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- What character set are statements in when they leave the client?

  The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

  **Note**
  
  Some character sets cannot be used as the client character set. See Impermissible Client Character Sets.

- What character set should the server translate statements to after receiving them?

  To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

  - The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See Section 10.3.8, “Character Set Introducers”.

  - `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, “Collation Coercibility in Expressions”).
What character set should the server translate query results to before shipping them back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
SET character_set_results = binary;
```

For more information about character sets and error messages, see Section 10.6, “Error Message Character Set”.

To see the values of the character set and collation system variables that apply to the current session, use this statement:

```
SELECT * FROM performance_schema.session_variables
WHERE VARIABLE_NAME IN ('character_set_client', 'character_set_connection', 'character_set_results', 'collation_connection') ORDER BY VARIABLE_NAME;
```

The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see all character set and collation system variables:

```
SHOW SESSION VARIABLES LIKE 'character\_set\_%';
SHOW SESSION VARIABLES LIKE 'collation\_%';
```

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings for each connection to the server.

### Impermissible Client Character Sets

The `character_set_client` system variable cannot be set to certain character sets:

```
ucs2
utf16
utf16le
utf32
```

Attempting to use any of those character sets as the client character set produces an error:

```
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
Client Program Connection Character Set Configuration

The SET CHARACTER SET 'charset_name' statement.

Client Program Connection Character Set Configuration

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from which the server can determine the character set.) The server uses this information to set the character_set_client, character_set_results, character_set_connection system variables to the character set, and collation_connection to the character set default collation. In effect, the server performs the equivalent of a SET NAMES operation.

If the server does not support the requested character set or collation, it falls back to using the server character set and collation to configure the connection. For additional detail about this fallback behavior, see Connection Character Set Error Handling.

The mysql, mysqladmin, mysqlcheck, mysqlimport, and mysqlshow client programs determine the default character set to use as follows:

- In the absence of other information, each client uses the compiled-in default character set, usually utf8mb4.

- Each client can autodetect which character set to use based on the operating system setting, such as the value of the LANG or LC_ALL locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting LANG to ru_RU.KOI8-R causes the koi8r character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

  The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, utf8 and utf-8 map to utf8mb4, and ucs2 is not supported as a connection character set, so it maps to the compiled-in default.

  C applications can use character set autodetection based on the OS setting by invoking mysql_options() as follows before connecting to the server:

  ```
  mysql_options(mysql, MYSQL_SET_CHARSET_NAME, MYSQL_AUTODETECT_CHARSET_NAME);
  ```

- Each client supports a --default-character-set option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

  **Note**

  Some character sets cannot be used as the client character set. Attempting to use them with --default-character-set produces an error. See Impermissible Client Character Sets.

With the mysql client, to use a character set different from the default, you could explicitly execute a SET NAMES statement every time you connect to the server (see Client Program Connection Character Set Configuration). To accomplish the same result more easily, specify the character set in your option file. For example, the following option file setting changes the three connection-related character set system variables set to koi8r each time you invoke mysql:

```
[mysql]
```
default-character-set=koi8r

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset koi8r
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

When configuration client programs, you must also consider the environment within which they execute. See Section 10.5, “Configuring Application Character Set and Collation”.

### SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using `SET` statements, but two more convenient statements affect the connection-related character set system variables as a group:

- **SET NAMES 'charset_name' [COLLATE 'collation_name']**

  `SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set cp1251.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement that produces a result set.)

  A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

  ```
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET character_set_connection = charset_name;
  ```

  Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation to use for `collation_connection`, add a `COLLATE` clause:

  ```
  SET NAMES 'charset_name' COLLATE 'collation_name'
  ```

- **SET CHARACTER SET 'charset_name'**

  `SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database` (which, as mentioned previously, indicate the character set and collation of the default database).

  A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

  ```
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET collation_connection = @@collation_database;
  ```

  Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.
Connection Character Set Error Handling

Note
Some character sets cannot be used as the client character set. Attempting to use them with \texttt{SET NAMES} or \texttt{SET CHARACTER SET} produces an error. See \textit{Impermissible Client Character Sets}.

Example: Suppose that \texttt{column1} is defined as \texttt{CHAR(5) CHARACTER SET latin2}. If you do not say \texttt{SET NAMES} or \texttt{SET CHARACTER SET}, then for \texttt{SELECT column1 FROM t}, the server sends back all the values for \texttt{column1} using the character set that the client specified when it connected. On the other hand, if you say \texttt{SET NAMES 'latin1'} or \texttt{SET CHARACTER SET 'latin1'} before issuing the \texttt{SELECT} statement, the server converts the \texttt{latin2} values to \texttt{latin1} just before sending results back. Conversion may be lossy for characters that are not in both character sets.

Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- Connect-Time Error Handling
- Runtime Error Handling

Connect-Time Error Handling

Some character sets cannot be used as the client character set; see \textit{Impermissible Client Character Sets}. If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
shell> mysql --default-character-set=ucs2
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If you specify a character set that the client does not recognize, it produces an error:

```
shell> mysql --default-character-set=bogus
mysql: Character set 'bogus' is not a compiled character set and is not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
ERROR 2019 (HY000): Can't initialize character set bogus (path: /usr/local/mysql/share/charsets/)
```

If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use \texttt{latin1} and \texttt{latin1_swedish_ci} as its defaults, and that it does not recognize \texttt{gb18030} as a valid character set. A client that specifies \texttt{--default-character-set=gb18030} is able to connect to the server, but the resulting character set is not what the client wants:

```
mysql> SHOW SESSION VARIABLES LIKE 'character_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
|--------------------------+--------+
| character_set_client     | latin1 |
| character_set_connection | latin1 |
| character_set_results    | latin1 |
| ...                      |        |
```

1658
Connection Character Set Error Handling

You can see that the connection system variables have been set to reflect a character set and collation of `latin1` and `latin1_swedish_ci`. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs in a more subtle context: When the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side. This occurs, for example, when a MySQL 8.0 client wants to connect to a MySQL 5.7 server using `utf8mb4` as the client character set. A client that specifies `--default-character-set=utf8mb4` is able to connect to the server. However, as in the previous example, the server falls back to its default character set and collation, not what the client requested:

```
mysql> SHOW SESSION VARIABLES LIKE 'character_set_\_%';
+--------------------------+--------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_set_client</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_connection</td>
<td>latin1</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>character_set_results</td>
<td>latin1</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

```
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+----------------------+-------------------+
| Variable_name        | Value             |
|----------------------+-------------------+
| collation_connection | latin1_swedish_ci |
```

Why does this occur? After all, `utf8mb4` is known to the 8.0 client and the 5.7 server, so both of them recognize it. To understand this behavior, it is necessary to understand that when the client tells the server which character set it wants to use, it really tells the server the default collation for that character set. Therefore, the aforementioned behavior occurs due to a combination of factors:

- The default collation for `utf8mb4` differs between MySQL 5.7 and 8.0 (`utf8mb4_general_ci` for 5.7, `utf8mb4_0900_ai_ci` for 8.0).
- When the 8.0 client requests a character set of `utf8mb4`, what it sends to the server is the default 8.0 `utf8mb4` collation; that is, the `utf8mb4_0900_ai_ci`.
- `utf8mb4_0900_ai_ci` is implemented only as of MySQL 8.0, so the 5.7 server does not recognize it.
- Because the 5.7 server does not recognize `utf8mb4_0900_ai_ci`, it cannot satisfy the client character set request, and falls back to its default character set and collation (`latin1` and `latin1_swedish_ci`).

In this case, the client can still use `utf8mb4` by issuing a `SET NAMES 'utf8mb4'` statement after connecting. The resulting collation is the 5.7 default `utf8mb4` collation; that is, `utf8mb4_general_ci`. 
If the client additionally wants a collation of `utf8mb4_0900_ai_ci`, it cannot achieve that because the server does not recognize that collation. The client must either be willing to use a different `utf8mb4` collation, or connect to a server from MySQL 8.0 or higher.

### Runtime Error Handling

Within an established connection, the client can request a change of connection character set and collation with `SET NAMES` or `SET CHARACTER SET`.

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```sql
mysql> SET NAMES 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```sql
mysql> SET NAMES 'bogus';
ERROR 1115 (42000): Unknown character set: 'bogus'

mysql> SET NAMES 'utf8mb4' COLLATE 'bogus';
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

**Tip**

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```sql
SELECT @@character_set_client;
```

### 10.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation (`utf8mb4`, `utf8mb4_0900_ai_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of `utf8mb4`, whereas applications that use another database might use `sjis`.

- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.

- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.
Configuring Application Character Set and Collation

The examples shown here assume use of the `latin1` character set and `latin1_swedish_ci` collation in particular contexts as an alternative to the defaults of `utf8mb4` and `utf8mb4_0900_ai_ci`.

- **Specify character settings per database.** To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```sql
CREATE DATABASE mydb
    CHARACTER SET latin1
    COLLATE latin1_swedish_ci;
```

Tables created in the database will use `latin1` and `latin1_swedish_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'latin1'` statement after connecting. The statement can be used regardless of connection method (the `mysql` client, PHP scripts, and so forth).

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using `mysql`, you can specify the `--default-character-set=latin1` command-line option to achieve the same effect as `SET NAMES 'latin1'`.

For more information about configuring client connections, see Section 10.4, “Connection Character Sets and Collations”.

**Note**

If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.)

- **Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```ini
[mysqld]
character-set-server=latin1
collation-server=latin1_swedish_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'latin1'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this may yield inconsistent results because the `init_connect` value is not executed for users who have the `CONNECTION_ADMIN` or `SUPER` privilege.

- **Specify character settings at MySQL configuration time.** To select a character set and collation if you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` CMake options:

```sh
cmake . -DDEFAULT_CHARSET=latin1
    -DDEFAULT_COLLATION=latin1_swedish_ci
```
The resulting server uses `latin1` and `latin1_swedish_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. For example, if you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

### 10.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see Section 10.11, "Setting the Error Message Language". For general information about configuring error logging, see Section 5.4.2, "The Error Log".

- Character Set for Error Message Construction
- Character Set for Error Message Disposition

#### Character Set for Error Message Construction

The server constructs error messages as follows:

- The message template uses UTF-8 (`utf8mb3`).
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
  - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
  - Character (nonbinary) string values are converted from their character set to UTF-8.
  - Binary string values are copied as is for bytes in the range `0x20` to `0x7E`, and using `\x` hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert `0x41CF9F` into a `VARBINARY` unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

```
Duplicate entry 'A\xC3\x9F' for key 1
```

#### Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

- If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.
If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the `character_set_results` system variable. If `character_set_results` has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8mb3` or `utf8mb4`, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (0x0000 to 0xFFFF) are written using `\\nnnn` notation.
- Characters outside the BMP range (0x10000 to 0x10FFFF) are written using `\\+nnnnnn` notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see Section 10.4, “Connection Character Sets and Collations”.

### 10.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.

- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```
UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);
```

Suppose that table `t` has a nonbinary column named `col1` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.
A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored \texttt{sjis} values in a column, even though MySQL's default character set was different. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was \texttt{latin1} and \texttt{col1} is defined as \texttt{CHAR(50)} but its contents are \texttt{sjis} values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY col1 BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as \texttt{INSERT} or \texttt{UPDATE} after an upgrade to MySQL 4.1 or later. In that case, MySQL would store new values in the column using \texttt{latin1}, and the column will contain a mix of \texttt{sjis} and \texttt{latin1} values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with \texttt{ALTER TABLE}. For example, if you specified \texttt{NOT NULL} and an explicit \texttt{DEFAULT} value, you should also provide them in the \texttt{ALTER TABLE} statement. Otherwise, the resulting column definition will not include those attributes.

To convert all character columns in a table, the \texttt{ALTER TABLE ... CONVERT TO CHARACTER SET charset} statement may be useful. See Section 13.1.9, “ALTER TABLE Syntax”.

### 10.8 Collation Issues

The following sections discuss various aspects of character set collations.

#### 10.8.1 Using COLLATE in SQL Statements

With the \texttt{COLLATE} clause, you can override whatever the default collation is for a comparison. \texttt{COLLATE} may be used in various parts of SQL statements. Here are some examples:

- With \texttt{ORDER BY}:

  ```
  SELECT k 
  FROM t1 
  ORDER BY k COLLATE latin1_german2_ci;
  ```

- With \texttt{AS}:

  ```
  SELECT k COLLATE latin1_german2_ci AS k1 
  FROM t1 
  ORDER BY k1;
  ```

- With \texttt{GROUP BY}:

  ```
  SELECT k 
  FROM t1 
  GROUP BY k COLLATE latin1_german2_ci;
  ```
• With aggregate functions:

```sql
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

• With `DISTINCT`:

```sql
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

• With `WHERE`:

```sql
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```sql
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

• With `HAVING`:

```sql
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

### 10.8.2 COLLATE Clause Precedence

The `COLLATE` clause has high precedence (higher than `||`), so the following two expressions are equivalent:

```sql
x || y COLLATE z
x || (y COLLATE z)
```

### 10.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```sql
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid for CHARACTER SET 'latin1'
```

### 10.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```sql
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```
However, with multiple operands, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should the comparison use the collation of the column \( x \), or of the string literal \( 'Y' \)? Both \( x \) and \( 'Y' \) have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as \( \text{CONCAT}(x, 'Y') \) combines its arguments to produce a single string. What collation should the result have?

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- An explicit \text{COLLATE} clause has a coercibility of 0 (not coercible at all).
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as \text{USER()} or \text{VERSION()}) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- The collation of a numeric or temporal value has a coercibility of 5.
- \text{NULL} or an expression that is derived from \text{NULL} has a coercibility of 6.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:
    ```
    SELECT CONCAT(utf8_column, latin1_column) FROM t1;
    ```
    It returns a result that has a character set of utf8 and the same collation as utf8_column. Values of latin1_column are automatically converted to utf8 before concatenating.
  - For an operation with operands from the same character set but that mix a \text{_bin} collation and a \text{_ci} or \text{_cs} collation, the \text{_bin} collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

The following table illustrates some applications of the preceding rules.
The binary Collation Compared to _bin Collations

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Collation Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>column1 = 'A'</td>
<td>Use collation of column1</td>
</tr>
<tr>
<td>column1 = 'A' COLLATE x</td>
<td>Use collation of 'A' COLLATE x</td>
</tr>
<tr>
<td>column1 COLLATE x = 'A' COLLATE y</td>
<td>Error</td>
</tr>
</tbody>
</table>

To determine the coercibility of a string expression, use the COERCIBILITY() function (see Section 12.15, “Information Functions”):

```sql
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
mysql> SELECT COERCIBILITY(1000);  
-> 5
```

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument 1 in the expression CONCAT(1, 'abc'), the result is a character (nonbinary) string that has a character set and collation determined by the character_set_connection and collation_connection system variables. See Section 12.2, “Type Conversion in Expression Evaluation”.

### 10.8.5 The binary Collation Compared to _bin Collations

This section describes how the binary collation for binary strings compares to the _bin collations for nonbinary strings.

Binary strings (as stored using the BINARY, VARBINARY, and BLOB data types) have a character set and collation named binary. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order.

Nonbinary strings (as stored using the CHAR, VARCHAR, and TEXT data types) have a character set and collation other than binary. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. One of these is the binary collation for the character set, indicated by a _bin suffix in the collation name. For example, the binary collations for latin1 and utf8 are named latin1_bin and utf8_bin, respectively.

The binary collation differs from the _bin collations in several respects.

**The unit for comparison and sorting.** Binary strings are sequences of bytes. For the binary collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For the _bin collation, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

**Character set conversion.** A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a _bin collation:

- When assigning column values from another column that has a different character set:

  ```sql
  UPDATE t1 SET utf8_bin_column=latin1_column;
  INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
  ```

- When assigning column values for INSERT or UPDATE using a string literal:
The binary Collation Compared to _bin Collations

SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');

• When sending results from the server to a client:

SET NAMES latin1;
SELECT utf8_bin_column FROM t2;

For binary string columns, no conversion occurs. For the preceding cases, the string value is copied byte-wise.

**Lettercase conversion.** Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for _bin collations that ignore lettercase for ordering:

```sql
mysql> SET NAMES latin1 COLLATE latin1_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-------------+-------------+
| LOWER('aA') | UPPER('zZ') |
| aa          | ZZ          |
+-------------+-------------+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must be converted to a nonbinary string:

```sql
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING latin1));
+-------------+-----------------------------------+
| LOWER('aA') | LOWER(CONVERT('aA' USING latin1)) |
| aA          | aa                                |
+-------------+-----------------------------------+
```

**Trailing space handling in comparisons.**
Most MySQL collations have a pad attribute of PAD SPACE. The exceptions are Unicode collations based on UCA 9.0.0 and higher, which have a pad attribute of NO PAD. (see Section 10.10.1, “Unicode Character Sets”).

To determine the pad attribute for a collation, use the INFORMATION_SCHEMA COLLATIONS table, which has a PAD_ATTRIBUTE column.

The pad attribute determines how trailing spaces are treated for comparison of nonbinary strings (CHAR, VARCHAR, and TEXT values). NO PAD collations treat spaces at the end of strings like any other character. For PAD SPACE collations, trailing spaces are insignificant in comparisons; strings are compared without regard to any trailing spaces:

```sql
mysql> SET NAMES utf8 COLLATE utf8_bin;
mysql> SELECT 'a' = 'a';
+----------------+
| 'a' = 'a'      |
| 1              |
+----------------+
```

For binary strings, all characters are significant in comparisons, including trailing spaces:
Examples of the Effect of Collation

Trailing space handling for inserts and retrievals. \texttt{CHAR(N)} columns store nonbinary strings. Values shorter than \( N \) characters are extended with spaces on insertion. For retrieval, trailing spaces are removed.

\texttt{BINARY(N)} columns store binary strings. Values shorter than \( N \) bytes are extended with \( 0x00 \) bytes on insertion. For retrieval, nothing is removed; a value of the declared length is always returned.

10.8.6 Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column \( X \) in table \( T \) has these \texttt{latin1} column values:

Muffler
Müller
MX Systems
MySQL

Suppose also that the column values are retrieved using the following statement:

\begin{verbatim}
SELECT X FROM T ORDER BY X COLLATE \texttt{collation_name};
\end{verbatim}

The following table shows the resulting order of the values if we use \texttt{ORDER BY} with different collations.

<table>
<thead>
<tr>
<th>\texttt{latin1_swedish_ci}</th>
<th>\texttt{latin1_german1_ci}</th>
<th>\texttt{latin1_german2_ci}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muffler</td>
<td>Muffler</td>
<td>Müller</td>
</tr>
<tr>
<td>MX Systems</td>
<td>Müller</td>
<td>Muffler</td>
</tr>
<tr>
<td>Müller</td>
<td>MX Systems</td>
<td>MX Systems</td>
</tr>
<tr>
<td>MySQL</td>
<td>MySQL</td>
<td>MySQL</td>
</tr>
</tbody>
</table>

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the \texttt{SELECT} using the Swedish/Finnish collating rule, which says that U-umlaut sorts with \( Y \).
• The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.

• The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

**Example 2: Searching for German Umlauts**

Suppose that you have three tables that differ only by the character set and collation used:

```sql
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (c CHAR(10)) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```sql
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```sql
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+------+
| c    |
| Bar  |
| Bär  |
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+------+
| c    |
| Bär  |
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+------+
| c    |
| Bar  |
| Bär  |
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

### 10.8.7 Using Collation in INFORMATION_SCHEMA Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8_general_ci`, which is case insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in `INFORMATION_SCHEMA` string columns can be case-sensitive or insensitive, depending on the characteristics of the underlying file system and the
lower_case_table_names system variable setting. For example, searches may be case-sensitive if the file system is case-sensitive. This section describes this behavior and how to modify it if necessary.

Suppose that a query searches the SCHEMATA.SCHEMA_NAME column for the test database. On Linux, file systems are case-sensitive, so comparisons of SCHEMATA.SCHEMA_NAME with 'test' match, but comparisons with 'TEST' do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'test';
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+
mysql>
```

These results occur if the lower_case_table_names system variable set to 0. A setting of 1 or 2 causes the second query to return the same (nonempty) result as the first query.

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

The value of lower_case_table_names makes no difference in this context.

The preceding behavior occurs because the utf8_general_ci collation is not used for INFORMATION_SCHEMA queries when searching for values that correspond to objects represented in the file system.

If the result of a string operation on an INFORMATION_SCHEMA column differs from expectations, a workaround is to use an explicit COLLATE clause to force a suitable collation (see Section 10.8.1, “Using COLLATE in SQL Statements”). For example, to perform a case-insensitive search, use COLLATE with the INFORMATION_SCHEMA column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEST</td>
</tr>
</tbody>
</table>
+-------------+
```
WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';

<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';

<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>

You can also use the `UPPER()` or `LOWER()` function:

WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8_bin`) is case sensitive; the others are not:

WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a "virtual" database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match 'information_schema' or 'INFORMATION_SCHEMA' regardless of platform:

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'information_schema';

<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>information_schema</td>
</tr>
</tbody>
</table>

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';

<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>information_schema</td>
</tr>
</tbody>
</table>

10.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the Unicode Consortium website.

BMP characters have these characteristics:
• Their code point values are between 0 and 65535 (or $U+0000$ and $U+FFFF$).
• They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
• They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
• They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

• Their code point values are between $U+10000$ and $U+10FFFF$).

• Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

• Basic Latin letters, digits, and punctuation signs use one byte.

• Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tildes, macrons, accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.

• Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:

• `utf8mb4`: A UTF-8 encoding of the Unicode character set using one to four bytes per character.

• `utf8mb3`: A UTF-8 encoding of the Unicode character set using one to three bytes per character.

• `utf8`: An alias for `utf8mb3`.

• `ucs2`: The UCS-2 encoding of the Unicode character set using two bytes per character.

• `utf16`: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.

• `utf16le`: The UTF-16LE encoding for the Unicode character set. Like `utf16` but little-endian rather than big-endian.

• `utf32`: The UTF-32 encoding for the Unicode character set using four bytes per character.

---

Note

The `utf8mb3` character set is deprecated and will be removed in a future MySQL release. Please use `utf8mb4` instead. Although `utf8` is currently an alias for `utf8mb3`, at that point `utf8` will become a reference to `utf8mb4`. To avoid ambiguity about the meaning of `utf8`, consider specifying `utf8mb4` explicitly for character set references instead of `utf8`.

Table 10.2, “Unicode Character Set General Characteristics”, summarizes the general characteristics of Unicode character sets supported by MySQL.

**Table 10.2 Unicode Character Set General Characteristics**

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Supported Characters</th>
<th>Required Storage Per Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb4, utf8</td>
<td>BMP only</td>
<td>1, 2, or 3 bytes</td>
</tr>
</tbody>
</table>
The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Supported Characters</th>
<th>Required Storage Per Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>ucs2</td>
<td>BMP only</td>
<td>2 bytes</td>
</tr>
<tr>
<td>utf8mb4</td>
<td>BMP and supplementary</td>
<td>1, 2, 3, or 4 bytes</td>
</tr>
<tr>
<td>utf16</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf16le</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf32</td>
<td>BMP and supplementary</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>

Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to '?'. When converted to a Unicode character set that supports only BMP characters (utf8mb3 or ucs2).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only utf8mb3 and ucs2 character sets, there are potential incompatibility issues for your applications; see Section 10.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”. That section also describes how to convert tables from the (3-byte) utf8mb3 to the (4-byte) utf8mb4, and what constraints may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are utf8mb4_danish_ci, utf8mb3_danish_ci, utf8_danish_ci, ucs2_danish_ci, utf16_danish_ci, and utf32_danish_ci. The exception is utf16le, which has only two collations. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 10.10.1, “Unicode Character Sets”.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly; for example, by issuing a `SET NAMES 'utf8mb4'` statement. Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See Impermissible Client Character Sets.

The following sections provide additional detail on the Unicode character sets in MySQL.

### 10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The utf8mb4 character set has these characteristics:

- Supports BMP and supplementary characters.
- Requires a maximum of four bytes per multibyte character.

utf8mb4 contrasts with the utf8mb3 character set, which supports only BMP characters and uses a maximum of three bytes per character:

- For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there will be none.
utf8mb4 is a superset of utf8mb3, so for an operation such as the following concatenation, the result has character set utf8mb4 and the collation of utf8mb4_col:

```sql
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the WHERE clause works according to the collation of utf8mb4_col:

```sql
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;
```

For information about data type storage as it relates to multibyte character sets, see String Type Storage Requirements.

## 10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

The utf8mb3 character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Requires a maximum of three bytes per multibyte character.

Applications that use UTF-8 data but require supplementary character support should use utf8mb4 rather than utf8mb3 (see Section 10.9.1, "The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)").

Exactly the same set of characters is available in utf8mb3 and ucs2. That is, they have the same repertoire.

utf8 is an alias for utf8mb3; the character limit is implicit, rather than explicit in the name.

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of utf8mb3 in statements to utf8, so in statements such as SHOW CREATE TABLE or SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS or SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS, users will see the name utf8 or utf8_collation_substring.

utf8mb3 is also valid in contexts other than CHARACTER_SET clauses. For example:

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```
10.9.3 The utf8 Character Set (Alias for utf8mb3)

utf8 is an alias for the utf8mb3 character set. For more information, see Section 10.9.2, “The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)”.

Note
The utf8mb3 character set is deprecated and will be removed in a future MySQL release. Please use utf8mb4 instead. Although utf8 is currently an alias for utf8mb3, at that point utf8 will become a reference to utf8mb4. To avoid ambiguity about the meaning of utf8, consider specifying utf8mb4 explicitly for character set references instead of utf8.

10.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example, LATIN CAPITAL LETTER A has the code 0x0041 and it is stored as a 2-byte sequence: 0x00 0x41. CYRILLIC SMALL LETTER YERU (Unicode 0x044B) is stored as a 2-byte sequence: 0x04 0x4B.

For Unicode characters and their codes, please refer to the Unicode Consortium website.

The ucs2 character set has these characteristics:

• Supports BMP characters only (no support for supplementary characters)
• Uses a fixed-length 16-bit encoding and requires two bytes per character.

10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The utf16 character set is the ucs2 character set with an extension that enables encoding of supplementary characters:

• For a BMP character, utf16 and ucs2 have identical storage characteristics: same code values, same encoding, same length.

• For a supplementary character, utf16 has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than 0xffff, take 10 bits and add them to 0xd800 and put them in the first 16-bit word, take 10 more bits and add them to 0xdc00 and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between 0xd800 and 0xdbff, and the last 16 bits are a number between 0xdc00 and 0xdfff. Examples are in Section 15.5 Surrogates Area of the Unicode 4.0 document.

Because utf16 supports surrogates and ucs2 does not, there is a validity check that applies only in utf16: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:
There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like 0xffff). For example, since U+F8FF is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column) VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a utf16 column or index is only half of the maximum length for a ucs2 column or index. For example, the maximum length of a MEMORY table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for ucs2 and utf16 columns:

```
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

10.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as utf16 but is little-endian rather than big-endian.

10.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The utf32 character set is fixed length (like ucs2 and unlike utf16). utf32 uses 32 bits for every character, unlike ucs2 (which uses 16 bits for every character), and unlike utf16 (which uses 16 bits for some characters and 32 bits for others).

utf32 takes twice as much space as ucs2 and more space than utf16, but utf32 has the same advantage as ucs2 that it is predictable for storage: The required number of bytes for utf32 equals the number of characters times 4. Also, unlike utf16, there are no tricks for encoding in utf32, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a utf8mb4 value given the utf32 code value:

```
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32, utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for utf32: No code value may be greater than 0x10ffff. For example, this is illegal:

```
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

10.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the utf8mb3 and utf8mb4 character sets.
Converting Between 3-Byte and 4-Byte Unicode Character Sets

This discussion focuses primarily on converting between utf8mb3 and utf8mb4, but similar principles apply to converting between the ucs2 character set and character sets such as utf16 or utf32.

The utf8mb3 and utf8mb4 character sets differ as follows:

- utf8mb3 supports only characters in the Basic Multilingual Plane (BMP). utf8mb4 additionally supports supplementary characters that lie outside the BMP.
- utf8mb3 uses a maximum of three bytes per character. utf8mb4 uses a maximum of four bytes per character.

One advantage of converting from utf8mb3 to utf8mb4 is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from utf8mb3 to utf8mb4 presents no problems:

- For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there will be none.

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (VARCHAR and the TEXT types), the maximum permitted length in characters is less for utf8mb4 columns than for utf8mb3 columns.
- For all character data types (CHAR, VARCHAR, and the TEXT types), the maximum number of characters that can be indexed is less for utf8mb4 columns than for utf8mb3 columns.

Consequently, to convert tables from utf8mb3 to utf8mb4, it may be necessary to change some column or index definitions.

Tables can be converted from utf8mb3 to utf8mb4 by using ALTER TABLE. Suppose that a table has this definition:

```sql
CREATE TABLE t1 (  
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,  
  col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL  
) CHARACTER SET utf8;
```

The following statement converts t1 to use utf8mb4:

```sql
ALTER TABLE t1  
DEFAULT CHARACTER SET utf8mb4,  
MODIFY col1 CHAR(10)  
    CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
```
The catch when converting from utf8mb3 to utf8mb4 is that the maximum length of a column or index key is unchanged in terms of bytes. Therefore, it is smaller in terms of characters because the maximum length of a character is four bytes instead of three. For the CHAR, VARCHAR, and TEXT data types, watch for these issues when converting your MySQL tables:

- Check all definitions of utf8mb3 columns and make sure they will not exceed the maximum length for the storage engine.
- Check all indexes on utf8mb3 columns and make sure they will not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use utf8mb3 rather than utf8mb4.

Here are some examples where structural changes may be needed:

- A TINYTEXT column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a TINYTEXT column that uses utf8mb3 but must be able to contain more than 63 characters. You cannot convert it to utf8mb4 unless you also change the data type to a longer type such as TEXT.

Similarly, a very long VARCHAR column may need to be changed to one of the longer TEXT types if you want to convert it from utf8mb3 to utf8mb4.

- **InnoDB** has a maximum index length of 767 bytes for tables that use COMPACT or REDUNDANT row format, so for utf8mb3 or utf8mb4 columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have utf8mb3 columns with indexes longer than 191 characters, you must index a smaller number of characters.

In an InnoDB table that uses COMPACT or REDUNDANT row format, these column and index definitions are legal:

```sql
col1 VARCHAR(500) CHARACTER SET utf8, INDEX (col1(255))
```

To use utf8mb4 instead, the index must be smaller:

```sql
col1 VARCHAR(500) CHARACTER SET utf8mb4, INDEX (col1(191))
```

**Note**

For InnoDB tables that use COMPRESSED or DYNAMIC row format, index key prefixes longer than 767 bytes (up to 3072 bytes) are permitted. Tables created with these row formats enable you to index a maximum of 1024 or 768 characters for utf8mb3 or utf8mb4 columns, respectively. For related information, see Section 15.6.1.6, “Limits on InnoDB Tables”, and DYNAMIC Row Format.

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from utf8mb3 to utf8mb4 without problems, using ALTER TABLE as described previously.

The following items summarize other potential incompatibilities:

- **SET NAMES 'utf8mb4'** causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications
that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.

- For replication, if character sets that support supplementary characters are to be used on the master, all slaves must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the master and slave, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use utf8mb3 on the master and utf8mb4 on the slave.

If you have converted to utf8mb4, utf16, utf16le, or utf32, and then decide to convert back to utf8mb3 or ucs2 (for example, to downgrade to an older version of MySQL), these considerations apply:

- utf8mb3 and ucs2 data should present no problems.
- The server must be recent enough to recognize definitions referring to the character set from which you are converting.
- For object definitions that refer to the utf8mb4 character set, you can dump them with mysqldump prior to downgrading, edit the dump file to change instances of utf8mb4 to utf8, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server will see utf8 in the dump file object definitions and create new objects that use the (3-byte) utf8 character set.

10.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA CHARACTER_SETS table. For example:

```
mysql> SHOW CHARACTER SET;
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
+----------+---------------------------------+---------------------+--------+
| armscii8 | ARMSCII-8 Armenian              | armscii8_general_ci | 1      |
| ascii    | US ASCII                        | ascii_general_ci    | 1      |
| big5     | Big5 Traditional Chinese        | big5_chinese_ci     | 2      |
| binary   | Binary pseudo charset           | binary              | 1      |
| cp1250   | Windows Central European        | cp1250_general_ci   | 1      |
| cp1251   | Windows Cyrillic                | cp1251_general_ci   | 1      |
| cp1256   | Windows Arabic                  | cp1256_general_ci   | 1      |
| cp1257   | Windows Baltic                  | cp1257_general_ci   | 1      |
| cp850    | DOS West European               | cp850_general_ci    | 1      |
| cp852    | DOS Central European            | cp852_general_ci    | 1      |
| cp866    | DOS Russian                     | cp866_general_ci    | 1      |
| cp932    | SJIS for Windows Japanese       | cp932_japanese_ci   | 2      |
| dec8     | DEC West European               | dec8_swedish_ci     | 1      |
| ecpjms   | UJIS for Windows Japanese       | ecpjms_japanese_ci  | 3      |
| euckr    | EUC-KR Korean                   | euckr_korean_ci     | 2      |
| gb18030  | China National Standard GB18030| gb18030_chinese_ci  | 4      |
| gb2312   | GB2312 Simplified Chinese       | gb2312_chinese_ci   | 2      |
| gbk      | GBK Simplified Chinese          | gbk_chinese_ci      | 2      |
| geostd8  | GEOSTD8 Georgian                | geostd8_general_ci  | 1      |
| greek    | ISO 8859-7 Greek                | greek_general_ci    | 1      |
| hebrew   | ISO 8859-8 Hebrew               | hebrew_general_ci   | 1      |
| hp3      | HP West European                | hp3_english_ci      | 1      |
| keybcs2  | DOS Kamenicky Czech-Slovak      | keybcs2_general_ci  | 1      |
| koi8r    | KOI8-R Relcom Russian           | koi8r_general_ci    | 1      |
| koi8u    | KOI8U Ukrainian                 | koi8u_general_ci    | 1      |
| latin1   | cp1252 West European            | latin1_swedish_ci   | 1      |
```
In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 10.10.1 Unicode Character Sets

MySQL supports multiple Unicode character sets:

- **utf8mb4**: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- **utf8mb3**: A UTF-8 encoding of the Unicode character set using one to three bytes per character. **Note**: The utf8mb3 character set is deprecated and will be removed in a future MySQL release. Please use utf8mb4 instead. Although utf8 is currently an alias for utf8mb3, at that point utf8 will become a reference to utf8mb4. To avoid ambiguity about the meaning of utf8, consider specifying utf8mb4 explicitly for character set references instead of utf8.
- **utf8**: An alias for utf8mb3.
- **ucs2**: The UCS-2 encoding of the Unicode character set using two bytes per character.
- **utf16**: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like ucs2 but with an extension for supplementary characters.
- **utf16le**: The UTF-16LE encoding for the Unicode character set. Like utf16 but little-endian rather than big-endian.
- **utf32**: The UTF-32 encoding for the Unicode character set using four bytes per character.

**Note**

utf8 and ucs2 support Basic Multilingual Plane (BMP) characters. utf8mb4, utf16, utf16le, and utf32 support BMP and supplementary characters.

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see Section 10.9, “Unicode Support”.

Most Unicode character sets have a general collation (indicated by _general in the name or by the absence of a language specifier), a binary collation (indicated by _bin in the name), and several language-specific collations (indicated by language specifiers). For example, for utf8, utf8_general_ci and utf8_bin are its general and binary collations, and utf8_danish_ci is one of its language-specific collations.
Collation support for utf16le is limited. The only collations available are utf16le_general_ci and utf16le_bin. These are similar to utf16_general_ci and utf16_bin.

A locale code or language name shown in the following table indicates a language-specific collation. Unicode character sets may include collations for one or more of these languages.

Table 10.3 Unicode Collation Language Specifiers

<table>
<thead>
<tr>
<th>Language</th>
<th>Language Specifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chinese</td>
<td>zh</td>
</tr>
<tr>
<td>Classical Latin</td>
<td>la or roman</td>
</tr>
<tr>
<td>Croatian</td>
<td>hr or croatian</td>
</tr>
<tr>
<td>Czech</td>
<td>cs or czech</td>
</tr>
<tr>
<td>Danish</td>
<td>da or danish</td>
</tr>

<tr>
<td>Swedish</td>
<td>sv or swedish</td>
</tr>
<tr>
<td>Turkish</td>
<td>tr or turkish</td>
</tr>
<tr>
<td>Vietnamese</td>
<td>vi or vietnamese</td>
</tr>
</tbody>
</table>

Croatian collations are tailored for these Croatian letters: Č, Ć, DŽ, Đ, Lj, Nj, Š, Ž.

Danish collations may also be used for Norwegian.

For Japanese, the utf8mb4 character set includes utf8mb4_ja_0900_as_cs and utf8mb4_ja_0900_as_cs_ks collations. Both collations are accent sensitive and case-sensitive. utf8mb4_ja_0900_as_cs_ks is also kana sensitive and distinguishes Katakana characters from Hiragana characters, whereas utf8mb4_ja_0900_as_cs treats Katakana and Hiragana characters as equal for sorting. Applications that require a Japanese collation but not kana sensitivity may use utf8mb4_ja_0900_as_cs for better sort performance. utf8mb4_ja_0900_as_cs_ks uses three weight levels for sorting; utf8mb4_ja_0900_as_cs_ks uses four.
For Classical Latin collations that are accent insensitive, \( I \) and \( J \) compare as equal, and \( U \) and \( V \) compare as equal. \( I \) and \( J \), and \( U \) and \( V \) compare as equal on the base letter level. In other words, \( J \) is regarded as an accented \( I \), and \( U \) is regarded as an accented \( V \).

Spanish collations are available for modern and traditional Spanish. For both, \( \tilde{n} \) (n-tilde) is a separate letter between \( n \) and \( o \). In addition, for traditional Spanish, \( ch \) is a separate letter between \( c \) and \( d \), and \( ll \) is a separate letter between \( l \) and \( m \).

Traditional Spanish collations may also be used for Asturian and Galician.

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

\[
\text{Ü} = \text{Y} < \text{Ö}
\]

For questions about particular language orderings, unicode.org provides Common Locale Data Repository (CLDR) collaboration charts at [http://www.unicode.org/cldr/charts/30/collation/index.html](http://www.unicode.org/cldr/charts/30/collation/index.html).

The xxx_general_mysql500_ci collations preserve the pre-5.1.24 ordering of the original xxx_general_ci collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

MySQL implements the xxx_unicode_ci collations according to the Unicode Collation Algorithm (UCA) described at [http://www.unicode.org/reports/tr10/](http://www.unicode.org/reports/tr10/). The collation uses the version-4.0.0 UCA weight keys: [http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt](http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt). The xxx_unicode_ci collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the `CHAR_LENGTH()` function or in result set metadata).

Unicode collations based on UCA versions later than 4.0.0 include the version in the collation name. Thus, `utf8mb4_unicode_520_ci` is based on UCA 5.2.0 weight keys ([http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt](http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt)), whereas `utf8mb4_0900_ai_ci` is based on UCA 9.0.0 weight keys ([http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt](http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt)).

Collations based on UCA 9.0.0 and higher are faster than collations based on UCA versions below 9.0.0. They also have a pad attribute of NO PAD, in contrast to PAD SPACE as used in collations based on UCA versions below 9.0.0. NO PAD collations treat spaces at the end of strings like any other character.

To determine the pad attribute for a collation, use the `INFORMATION_SCHEMA` `COLLATIONS` table, which has a `PAD_ATTRIBUTE` column.

Comparisons of `VARCHAR` columns that have a NO PAD collation differ from other collations with respect to trailing spaces. For example, `'a'` and `'a '` compare as different strings, not the same string.

MySQL implements language-specific Unicode collations if the ordering based only on UCA does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules.

For example, the nonlanguage-specific `utf8mb4_0900_ai_ci` and language-specific `utf8mb4_LOCALE_0900_ai_ci` Unicode collations each have these characteristics:

- The collation is based on Unicode Collation Algorithm (UCA) 9.0.0 and Common Locale Data Repository (CLDR) v30, is accent insensitive, and case insensitive. These characteristics are indicated by `_0900`, `_ai`, and `_ci` in the collation name. Exception: `utf8mb4_la_0900_ai_ci` is not based on CLDR because Classical Latin is not defined in CLDR.

- The collation works for all characters in the range [U+0, U+10FFFF].
• If the collation is not language specific, it sorts all characters, including supplementary characters, in default order (described following). If the collation is language specific, it sorts characters of the language correctly according to language-specific rules, and characters not in the language in default order.

• By default, the collation sorts characters having a code point listed in the DUCET table (Default Unicode Collation Element Table) according to the weight value assigned in the table. The collation sorts characters not having a code point listed in the DUCET table using their implicit weight value, which is constructed according to the UCA.

• For non-language-specific collations, characters in contraction sequences are treated as separate characters. For language-specific collations, contractions might change character sorting order.

`LOWER()` and `UPPER()` perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version more recent than 4.0.0 is converted by these functions only if the argument has a collation that uses a recent enough UCA version.

For any Unicode character set, operations performed using the `xxx_general_ci` collation are faster than those for the `xxx_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason for this is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages `ß` is equal to `ss`. `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect of this in comparisons or searches, see Section 10.8.6, “Examples of the Effect of Collation”):

- Ä = A
- Ö = O
- Ü = U

A difference between the collations is that this is true for `utf8_general_ci`:

- ß = s

Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

- ß = ss

MySQL implements `utf8` language-specific collations if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that `ß` is equal to `s`, and not to `ss`. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the `utf8_german2_ci` collation, which compares the following sets of characters equal:

- Ä = Å = AE
- Ö = ÖE = OE
UTF8_GERMAN2_CI is similar to LATIN1_GERMAN2_CI, but the latter does not compare Ä equal to AE or Ö equal to OE. There is no UTF8_GERMAN_CI corresponding to LATIN1_GERMAN_CI for German dictionary order because UTF8_GENERAL_CI suffices.

For all Unicode collations except the binary (_BIN) collations, MySQL performs a table lookup to find a character’s collating weight. This weight can be displayed using the WEIGHT_STRING() function. (See Section 12.5, “String Functions”.) If a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (XXX_GENERAL_CI), weight = code point.
- For BMP characters in UCA collations (for example, XXX_UNICODE_CI and language-specific collations), the following algorithm applies:

```sql
if (code >= 0x3400 && code <= 0x4DB5)
    base = 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base = 0xFB40; /* CJK Ideograph */
else
    base = 0xFBC0; /* All other characters */

aaaa = base + (code >> 15);
bbbb = (code & 0x7FFF) | 0x8000;
```

The result is a sequence of two collating elements, aaaa followed by bbbb. For example:

```sql
mysql> SELECT HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci));
+----------------------------------------------------------+
| HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci)) |
+----------------------------------------------------------+
| FBFC084CF                                                 |
+----------------------------------------------------------+
```

Thus, U+04cf CYRILLIC SMALL LETTER PALOCHKA is, with all UCA 4.0.0 collations, greater than U+04c0 CYRILLIC LETTER PALOCHKA. With UCA 5.2.0 collations, all palochkas sort together.

- For supplementary characters in general collations, the weight is the weight for 0xffff REPLACEMENT CHARACTER. For supplementary characters in UCA 4.0.0 collations, their collating weight is 0xffff. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and COUNT(DISTINCT):

```sql
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xffff);   /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL XXX_UNICODE_CI collations, the replacement character has a weight of 0x0dc6, whereas Deseret Bee and Deseret Tee both have a weight of 0xffff. (Were the UTF32_GENERAL_CI collation used instead, the result is 1 because all three characters have a weight of 0xffff in that collation.)

An example with cuneiform characters and WEIGHT_STRING():

```sql
```
/*
The four characters in the INSERT string are
00000041  # LATIN CAPITAL LETTER A
0001218F  # CUNEIFORM SIGN KAB
000121A7  # CUNEIFORM SIGN KISH
00000042  # LATIN CAPITAL LETTER B
*/
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;

The result is:

0E33 FFFD FFFD 0E4A

0E33 and 0E4A are primary weights as in UCA 4.0.0. FFFD is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to
cause trouble. These characters are very rare, so it is very rare that a multi-character string consists
entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji
ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted
by the MySQL rule and secondarily by code point value, it is easy:

ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin

• For supplementary characters based on UCA versions higher than 4.0.0 (for example,
  xxx_unicode_520_ci), supplementary characters do not necessarily all have the same collation
  weight. Some have explicit weights from the UCA allkeys.txt file. Others have weights calculated
  from this algorithm:

    aaaa= base + (code >> 15);
    bbbb= (code & 0x7FFF) | 0x8000;

There is a difference between “ordering by the character's code value” and “ordering by the character's
binary representation,” a difference that appears only with utf16_bin, because of surrogates.

Suppose that utf16_bin (the binary collation for utf16) was a binary comparison “byte by byte” rather
than “character by character.” If that were so, the order of characters in utf16_bin would differ from
the order in utf8_bin. For example, the following chart shows two rare characters. The first character
is in the range E000-FFFF, so it is greater than a surrogate but less than a supplementary. The second
character is a supplementary.

<table>
<thead>
<tr>
<th>Code point</th>
<th>Character</th>
<th>utf8</th>
<th>utf16</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF9D</td>
<td>HALFWIDTH Katakana Letter N</td>
<td>EF BE 9D</td>
<td>FF 9D</td>
</tr>
<tr>
<td>10384</td>
<td>Ugaritic Letter Delta</td>
<td>F0 90 8E 84</td>
<td>D8 00 DF 84</td>
</tr>
</tbody>
</table>

The two characters in the chart are in order by code point value because 0xff9d < 0x10384. And they
are in order by utf8 value because 0xef < 0xf0. But they are not in order by utf16 value, if we use
byte-by-byte comparison, because 0xff > 0xd8.

So MySQL’s utf16_bin collation is not “byte by byte.” It is “by code point.” When MySQL sees a
supplementary-character encoding in utf16, it converts to the character's code-point value, and then
compares. Therefore, utf8_bin and utf16_bin are the same ordering. This is consistent with the
SQL:2008 standard requirement for a UCS_BASIC collation: “UCS_BASIC is a collation in which the
ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted.
It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer."

If the character set is ucs2, comparison is byte-by-byte, but ucs2 strings should not contain surrogates, anyway.

10.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- ascii (US ASCII) collations:
  - ascii_bin
  - ascii_general_ci (default)
- cp850 (DOS West European) collations:
  - cp850_bin
  - cp850_general_ci (default)
- dec8 (DEC Western European) collations:
  - dec8_bin
  - dec8_swedish_ci (default)
- hp8 (HP Western European) collations:
  - hp8_bin
  - hp8_english_ci (default)
- latin1 (cp1252 West European) collations:
  - latin1_bin
  - latin1_danish_ci
  - latin1_general_ci
  - latin1_general_cs
  - latin1_german1_ci
  - latin1_german2_ci
  - latin1_spanish_ci
  - latin1_swedish_ci (default)

MySQL's latin1 is the same as the Windows cp1252 character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) latin1, except that IANA latin1 treats the code points between 0x80 and 0x9f as “undefined,” whereas cp1252, and therefore MySQL's latin1, assign characters for those positions. For example, 0x80 is the Euro sign.
“undefined” entries in cp1252, MySQL translates 0x81 to Unicode 0x0081, 0x8d to 0x008d, 0x8f to 0x008f, 0x90 to 0x0090, and 0x9d to 0x009d.

The latin1_swedish_ci collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The latin1_german1_ci and latin1_german2_ci collations are based on the DIN-1 and DIN-2 standards, where DIN stands for Deutsches Institut für Normung (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see Section 10.8.6, “Examples of the Effect of Collation”.

• latin1_german1_ci (dictionary) rules:
  
  | Ä | A |
  | Ö | O |
  | Ü | U |
  | Ñ | s |

• latin1_german2_ci (phone-book) rules:
  
  | Ä | AE |
  | Ö | OE |
  | Ü | UE |
  | ß | ss |

In the latin1_spanish_ci collation, ñ (n-tilde) is a separate letter between n and o.

• macroman (Mac West European) collations:
  
  | macroman_bin |
  | macroman_general_ci (default) |

• swe7 (7bit Swedish) collations:
  
  | swe7_bin |
  | swe7_swedish_ci (default) |

**10.10.3 Central European Character Sets**

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

• cp1250 (Windows Central European) collations:
  
  | cp1250_bin |
  | cp1250_croatian_ci |
  | cp1250_czech_cs |
  | cp1250_general_ci (default) |
  | cp1250_polish_ci |
South European and Middle East Character Sets

- **cp852** (DOS Central European) collations:
  - `cp852_bin`
  - `cp852_general_ci` (default)
- **keybcs2** (DOS Kamenicky Czech-Slovak) collations:
  - `keybcs2_bin`
  - `keybcs2_general_ci` (default)
- **latin2** (ISO 8859-2 Central European) collations:
  - `latin2_bin`
  - `latin2_croatian_ci`
  - `latin2_czech_cs`
  - `latin2_general_ci` (default)
  - `latin2_hungarian_ci`
- **macce** (Mac Central European) collations:
  - `macce_bin`
  - `macce_general_ci` (default)

10.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- **armscii8** (ARMSCEII-8 Armenian) collations:
  - `armscii8_bin`
  - `armscii8_general_ci` (default)
- **cp1256** (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)
- **geostd8** (GEOSTD8 Georgian) collations:
  - `geostd8_bin`
  - `geostd8_general_ci` (default)
- **greek** (ISO 8859-7 Greek) collations:
  - `greek_bin`
  - `greek_general_ci` (default)
- **hebrew** (ISO 8859-8 Hebrew) collations:
10.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- cp1257 (Windows Baltic) collations:
  - cp1257_bin
  - cp1257_general_ci (default)
  - cp1257_lithuanian_ci
- latin7 (ISO 8859-13 Baltic) collations:
  - latin7_bin
  - latin7_estonian_cs
  - latin7_general_ci (default)
  - latin7_general_cs

10.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- cp1251 (Windows Cyrillic) collations:
  - cp1251_bin
  - cp1251_bulgarian_ci
  - cp1251_general_ci (default)
  - cp1251_general_cs
  - cp1251_ukrainian_ci
- cp866 (DOS Russian) collations:
  - cp866_bin
  - cp866_general_ci (default)
- koi8r (KOI8-R Relcom Russian) collations:
  - koi8r_bin
Asian Character Sets

- koi8r_general_ci (default)
- koi8u (KOI8-U Ukrainian) collations:
  - koi8u_bin
  - koi8u_general_ci (default)

10.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See Section 10.10.7.1, “The cp932 Character Set”, for additional information about the cp932 and sjis character sets. See Section 10.10.7.2, “The gb18030 Character Set”, for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see Section A.11, “MySQL 8.0 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”.

- big5 (Big5 Traditional Chinese) collations:
  - big5_bin
  - big5_chinese_ci (default)
- cp932 (SJIS for Windows Japanese) collations:
  - cp932_bin
  - cp932_japanese_ci (default)
- eucjpms (UJIS for Windows Japanese) collations:
  - eucjpms_bin
  - eucjpms_japanese_ci (default)
- euckr (EUC-KR Korean) collations:
  - euckr_bin
  - euckr_korean_ci (default)
- gb2312 (GB2312 Simplified Chinese) collations:
  - gb2312_bin
  - gb2312_chinese_ci (default)
- gbk (GBK Simplified Chinese) collations:
  - gbk_bin
  - gbk_chinese_ci (default)
- gb18030 (China National Standard GB18030) collations:
  - gb18030_bin
Asian Character Sets

- `gb18030_chinese_ci` (default)
- `gb18030_unicode_520_ci`
- `sjis` (Shift-JIS Japanese) collations:
  - `sjis_bin`
  - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

10.10.7.1 The `cp932` Character Set

**Why is `cp932` needed?**

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See [http://www.iana.org/assignments/character-sets](http://www.iana.org/assignments/character-sets).)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

**How does `cp932` differ from `sjis`?**
The \texttt{cp932} character set differs from \texttt{sjis} in the following ways:

- \texttt{cp932} supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some \texttt{cp932} characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to \texttt{cp932}, one of the code points must be selected. For this "round trip conversion," the rule recommended by Microsoft is used. (See \url{http://support.microsoft.com/kb/170559/EN-US/}.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at \url{https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx} provides information about the Unicode values of \texttt{cp932} characters. For \texttt{cp932} table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (\texttt{ucs2}) encoding. For table entries with an underlined two-digit value appears, there is a range of \texttt{cp932} character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the \texttt{cp932} characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte \texttt{0x87}):
  \url{https://msdn.microsoft.com/en-us/goglobal/gg674964}
- NEC selected—IBM extended characters (lead byte \texttt{0xED} and \texttt{0xEE}):
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671837}
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671838}
- IBM selected characters (lead byte \texttt{0xFA}, \texttt{0xFB}, \texttt{0xFC}):
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671839}
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671840}
  \url{https://msdn.microsoft.com/en-us/goglobal/gg671841}
- \texttt{cp932} supports conversion of user-defined characters in combination with \texttt{eucjpms}, and solves the problems with \texttt{sjis/ujis} conversion. For details, please refer to \url{http://www.sljfaq.org/afaq/encodings.html}.

For some characters, conversion to and from \texttt{ucs2} is different for \texttt{sjis} and \texttt{cp932}. The following tables illustrate these differences.

<table>
<thead>
<tr>
<th>\texttt{sjis/cp932} Value</th>
<th>\texttt{sjis -&gt; ucs2} Conversion</th>
<th>\texttt{cp932 -&gt; ucs2} Conversion</th>

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See Section 5.1.7, “Server Command Options”.

#### 10.10.7.2 The gb18030 Character Set

In MySQL, the gb18030 character set corresponds to the “Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set”, which is the official character set of the People’s Republic of China (PRC).

**Characteristics of the MySQL gb18030 Character Set**

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as `?` (0x3F). Conversion of unassigned code points return `?`.
The Binary Character Set

- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on CaseFolding-6.3.0.txt).

- Supports Conversion of data to and from other character sets.

- Supports SQL statements such as SET NAMES.

- Supports comparison between gb18030 strings, and between gb18030 strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.

- The private use area (U+E000, U+F8FF) in Unicode is mapped to gb18030.

- There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '?'.

- If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in CONVERT(), an error is returned. Otherwise, a warning is returned.

- For consistency with utf8 and utf8mb4, UPPER is not supported for ligatures.

- Searches for ligatures also match uppercase ligatures when using the gb18030_unicode_520_ci collation.

- If a character has more than one uppercase character, the chosen uppercase character is the one whose lowercase is the character itself.

- The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a sequence using the first 1 or 2 bytes.

**Supported Collations**

- gb18030_bin: A binary collation.

- gb18030_chinese_ci: The default collation, which supports Pinyin. Sorting of non-Chinese characters is based on the order of the original sort key. The original sort key is GB(UPPER(ch)) if UPPER(ch) exists. Otherwise, the original sort key is GB(ch). Chinese characters are sorted according to the Pinyin collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters are sorted before Chinese characters with the exception of GB+FE39FE39, which is the code point maximum.

- gb18030_unicode_520_ci: A Unicode collation. Use this collation if you need to ensure that ligatures are sorted correctly.

### 10.10.8 The Binary Character Set

The binary character set is the character set of binary strings, which are sequences of bytes. The binary character set has one collation, also named binary. Comparison and sorting are based on numeric byte values. The effect is that lettercase and accent differences are significant in comparisons. That is, the binary collation is case-sensitive and accent sensitive.

```sql
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+----------------+------------------+
| CHARSET('abc') | COLLATION('abc') |
|----------------+------------------|
| binary         | binary           |
```
Setting the Error Message Language

For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

To convert a string expression to a binary string, any of these constructs are equivalent:

- `BINARY expr`
- `CAST(expr AS BINARY)`
- `CONVERT(expr USING BINARY)`

If `expr` is a character string literal, the `_binary` introducer may be used to designate it as a binary string. For example:

- `_binary 'a'`

The `_binary` introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see Section 10.3.8, “Character Set Introducers”.

10.11 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see Section 10.6, “Error Message Character Set”. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

The server searches for the error message file using these rules:

- It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

  `mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR`

  In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

  By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.
• If the server cannot find the configured message file, it writes a message to the error log to indicate the problem and defaults to built-in English messages.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```
SET lc_messages = 'en_US';
```

### 10.12 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```
<charset name="latin1">
  <family>Western</family>
  <description>cp1252 West European</description>
  ...  
  <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
    <flag>primary</flag>
    <flag>compiled</flag>
  </collation>
  <collation name="latin1_danish_ci" id="15" order="Danish"/>
  ...  
  <collation name="latin1_bin" id="47" order="Binary">
    <flag>binary</flag>
    <flag>compiled</flag>
  </collation>
  ...  
</charset>
```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of `general_ci` (general, case insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:
2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See Section 10.12.1, “Character Definition Arrays”.
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 10.12.1, “Character Definition Arrays”.
- For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
- If the character set requires string collating functions, see Section 10.12.2, “String Collating Support for Complex Character Sets”.
- If the character set requires multibyte character support, see Section 10.12.3, “Multi-Byte Character Support for Complex Character Sets”.

3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```c
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```c
#ifdef HAVE_CHARSET_MYSET
add_compiled_collation(&my_charset_MYSET_general_ci);
add_compiled_collation(&my_charset_MYSET_bin);
#endif
```
b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.

c. Edit `cmake/character_sets.cmake`:
   
i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.
   
   ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or `CMake` will not recognize `-DDEFAULT_CHARSET=MYSET`.

4. Reconfigure, recompile, and test.

### 10.12.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling `EOF`.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```c
#define _MY_U   01      /* Upper case */
#define _MY_L   02      /* Lower case */
#define _MY_NMR 04      /* Numeral (digit) */
#define _MY_SPC 010     /* Spacing character */
#define _MY_PNT 020     /* Punctuation */
#define _MY_CTR 040     /* Control character */
#define _MY_B   0100    /* Blank */
#define _MY_X   0200    /* heXadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, `'A'` is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
cctype['A'+1] = _MY_U | _MY_X = 01 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.
The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```plaintext
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in Section 10.12.2, “String Collating Support for Complex Character Sets”.

### 10.12.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.12.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.13 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The `WEIGHT_STRING()` function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use `HEX(WEIGHT_STRING(str))` to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in 'AaBb' if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```sql
mysql> SELECT HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci));
```
MySQL supports several collation implementations, as discussed in Section 10.13.1, “Collation Implementation Types”. Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (xxx_bin) collations.

The following sections describe how to add collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the collation is present.

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in Section 10.12, “Adding a Character Set”. However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

**Note**

If you modify an existing collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. See Section 2.11.13, “Rebuilding or Repairing Tables or Indexes”.

### Additional Resources

- The Unicode Collation Algorithm (UCA) specification: [http://www.unicode.org/reports/tr10/](http://www.unicode.org/reports/tr10/)
- The Locale Data Markup Language (LDML) specification: [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/)

#### 10.13.1 Collation Implementation Types

MySQL implements several types of collations:
Collation Implementation Types

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```sql
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-------------------------+-------------------------+
<table>
<thead>
<tr>
<th>HEX(WEIGHT_STRING('a'))</th>
<th>HEX(WEIGHT_STRING('A'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>41</td>
</tr>
</tbody>
</table>
+-------------------------+-------------------------+
1 row in set (0.01 sec)
```

For implementation instructions, see Section 10.13.3, “Adding a Simple Collation to an 8-Bit Character Set”.

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in Section 10.12, “Adding a Character Set”.

Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multibyte character ‘ぢ’ has a character code of 0x82C0, and the weight is also 0x82C0.

```sql
mysql> CREATE TABLE t1
    -> (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x82C0);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+------+---------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>41</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>41</td>
</tr>
<tr>
<td>ぢ</td>
<td>82C0</td>
<td>82C0</td>
</tr>
</tbody>
</table>
+------+---------+------------------------+
3 rows in set (0.00 sec)
```
Collation Implementation Types

• Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multibyte character '膰' has a character code of 0x81B0 but a weight of 0xC286.

```sql
mysql> CREATE TABLE t1
    
    (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x81B0);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+------+---------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>41</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>41</td>
</tr>
<tr>
<td>膰</td>
<td>81B0</td>
<td>C286</td>
</tr>
</tbody>
</table>
+------+---------+------------------------+
3 rows in set (0.00 sec)
```

For implementation instructions, see Section 10.12, "Adding a Character Set".

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case insensitive and accent insensitive. `utf8_general_ci` is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.

```sql
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1
    
    (c1 CHAR(1) CHARACTER SET UTF8 COLLATE utf8_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('À'),('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+------+---------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>0041</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>0041</td>
</tr>
<tr>
<td>À</td>
<td>C380</td>
<td>0041</td>
</tr>
<tr>
<td>á</td>
<td>C3A1</td>
<td>0041</td>
</tr>
</tbody>
</table>
+------+---------+------------------------+
4 rows in set (0.00 sec)
```

UCA-based collations in MySQL have these properties:

• If a character has weights, each weight uses 2 bytes (16 bits).

• A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.

• A character may have one weight. Example: 'a' has a weight of 0x0E33.
Choosing a Collation ID

A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.

Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see Section 10.12, “Adding a Character Set”. For a UCA collation, see Section 10.13.4, “Adding a UCA Collation to a Unicode Character Set”.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.13.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations. The collation ID that you choose will appear in these contexts:

- The ID column of the INFORMATION_SCHEMA.COLLATIONS table.
- The Id column of SHOW COLLATION output.
Adding a Simple Collation to an 8-Bit Character Set

- The `charsetnr` member of the `MYSQL_FIELD` C API data structure.
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function.

To determine the largest currently used ID, issue the following statement:

```sql
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

+---------+
| MAX(ID) |
+---------+
| 210     |
+---------+

To display a list of all currently used IDs, issue this statement:

```sql
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
```

+-----+
| ID   |
+-----+
| 1    |
| 2    |
| ...  |
| 52   |
| 53   |
| 57   |
| 58   |
| ...  |
| 98   |
| 99   |
| 128  |
| 129  |
| ...  |
| 210  |
+-----+

**Warning**

Before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

### 10.13.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in Section 10.13.2, “Choosing a Collation ID”. The following steps use an ID of 1024.

2. Modify the `Index.xml` and `latin1.xml` configuration files. These files are located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```sql
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
```

+---------------------+-----------------------------------------+
| Variable_name        | Value                                   |
+---------------------+-----------------------------------------+
3. Choose a name for the collation and list it in the Index.xml file. Find the <charset> element for the character set to which the collation is being added, and add a <collation> element that indicates the collation name and ID, to associate the name with the ID. For example:

```
<charset name="latin1">
  ...
  <collation name="latin1_test_ci" id="1024"/>
  ...
</charset>
```

4. In the latin1.xml configuration file, add a <collation> element that names the collation and that contains a <map> element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the <map> element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
  <map>
    00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
    10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
    20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
    30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
    40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
    50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
    60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
    70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
    80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
    90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
    AA AB AC AD AE AF
    BB BC BD BE BF
    41 41 41 41 4D 4D 4D 4D 4D 4D 4D 4D 4D 4D 4D 4D
    44 4E 4F 4F 4F 4F 4F 4F 4F 4F 4F 4F 4F 4F 4F 4F
    44 44 44 44 44 44 44 44 44 44 44 44 44 44 44 44
    44 44 44 44 44 44 44 44 44 44 44 44 44 44 44 44
  </map>
</collation>
```

5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'latin1_test_ci';
+----------------+---------+------+---------+----------+---------+
| Collation      | Charset | Id   | Default | Compiled | Sortlen |
+----------------+---------+------+---------+----------+---------+
| latin1_test_ci | latin1  | 1024 |       |          |       1 |
+----------------+---------+------+---------+----------+---------+
```

10.13.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the <collation> element within a <charset> character set description in the MySQL Index.xml file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at http://www.unicode.org/reports/tr35/. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for utf16le; there is no utf16le_unicode_ci collation that would serve as the basis for such collations.
### Adding a UCA Collation to a Unicode Character Set

Table 10.4 MySQL Character Sets Available for User-Defined UCA Collations

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Base Collation</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8</td>
<td>utf8_unicode_ci</td>
</tr>
<tr>
<td>ucs2</td>
<td>ucs2_unicode_ci</td>
</tr>
<tr>
<td>utf16</td>
<td>utf16_unicode_ci</td>
</tr>
<tr>
<td>utf32</td>
<td>utf32_unicode_ci</td>
</tr>
</tbody>
</table>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

#### 10.13.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see [Section 10.13.4.2, “LDML Syntax Supported in MySQL”](#).

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

- +7-12345-67
- +7-12-345-67
- +7 12 345 67
- +7 (12) 345 67
- +71234567

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 10.13.2, “Choosing a Collation ID”](#). The following steps use an ID of 1029.

2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

   ```
   mysql> SHOW VARIABLES LIKE 'character_sets_dir';
   +----------------+-----------------------------------------+
   | Variable_name  | Value                                   |
   +----------------+-----------------------------------------+
   | character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
   +----------------+-----------------------------------------+
   ```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

   ```xml
   <charset name="utf8">
     ...
     <collation name="utf8_phone_ci" id="1029">
       <rules>
         <reset> </reset>
       </rules>
   ```

   ```xml
   ```

   ```xml
   ```

1707
4. If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.

5. Restart the server and use this statement to verify that the collation is present:

```sql
mysql> SHOW COLLATION WHERE Collation = 'utf8_phone_ci';
+---------------+---------+------+---------+----------+---------+
| Collation     | Charset | Id   | Default | Compiled | Sortlen |
+---------------+---------+------+---------+----------+---------+
| utf8_phone_ci | utf8    | 1029 |         |          |       8 |
+---------------+---------+------+---------+----------+---------+
```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```sql
mysql> CREATE TABLE phonebook (
    name VARCHAR(64),
    phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci
);
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```sql
mysql> SELECT * FROM phonebook ORDER BY phone;
+---------+--------------------+
| name    | phone              |
+---------+--------------------+
| Sanja   | +380 (912) 8008005 |
| Bar     | +7-912-800-80-01   |
| Svoj    | +7 912 800 80 02   |
| Ramil   | (7912) 800 80 03   |
| Hf      | +7 (912) 800 80 04 |
+---------+--------------------+
5 rows in set (0.00 sec)
```
10.13.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at http://www.unicode.org/reports/tr35/, which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL Index.xml file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the Index.xml file. See Section 10.13.4.3, “Diagnostics During Index.xml Parsing”.

Character Representation

Characters named in LDML rules can be written literally or in \u\nnnn format, where nnnn is the hexadecimal Unicode code point value. For example, A and á can be written literally or as \u0041 and \u00E1. Within hexadecimal values, the digits A through F are not case-sensitive; \u00E1 and \u00e1 are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of 0000 to FFFF. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.

The Index.xml file itself should be written using UTF-8 encoding.

Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

• A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter 'A':

mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+------+------------------+
| name | phone            |
+------+------------------+
| Bar  | +7-912-800-80-01 |
+------+------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+------+------------------+
| name | phone            |
+------+------------------+

The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:

- Use primary differences to distinguish separate letters.
- Use secondary differences to distinguish accent variations.
- Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the 'G' character:

The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause 'b' to sort the same as 'a':

Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

**Table 10.5 Abbreviated Shift Syntax**

<table>
<thead>
<tr>
<th>Abbreviated Syntax</th>
<th>Nonabbreviated Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;pc&gt;xyz&lt;/pc&gt;</code></td>
<td><code>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</code></td>
</tr>
<tr>
<td><code>&lt;sc&gt;xyz&lt;/sc&gt;</code></td>
<td><code>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</code></td>
</tr>
<tr>
<td><code>&lt;tc&gt;xyz&lt;/tc&gt;</code></td>
<td><code>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</code></td>
</tr>
<tr>
<td><code>&lt;ic&gt;xyz&lt;/ic&gt;</code></td>
<td><code>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</code></td>
</tr>
</tbody>
</table>

An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```xml
<reset>abc</reset>
<reset>\u0041</reset>
```
- Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```xml
<reset>cc</reset>
<x>c<k>s</x><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```xml
<reset>cs</reset>
<x>c<tt>ccs</tt><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

- Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```xml
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

- Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```xml
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

- Reset rules permit a `<before>` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `<before>` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```xml
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `<before>` attribute values specify the sort level by name or the equivalent numeric value:

```xml
<reset before="primary"/>
<reset before="1"/>
<reset before="secondary"/>
<reset before="2"/>
<reset before="tertiary"/>
<reset before="3"/>
```

- A reset rule can name a logical reset position rather than a literal character:

```xml
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
<first_primary_ignorable/>
```
These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

```
<reset><last_non_ignorable/></reset>
<p>z</p>
```

Logical positions have the code points shown in the following table.

**Table 10.6 Logical Reset Position Code Points**

<table>
<thead>
<tr>

</tbody>
</table>

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
  - **simple**: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
  - **expand**: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of **0E29** and **0E2A** and we want to put all basic Latin letters between '0' and '1':

```
<reset>0</reset>
<p>aabcdefghjklmnopqrstuvwxyz</p>
```

For simple shift mode, weights are calculated as follows:

'\text{a}' has weight \text{0E29+1}
'\text{b}' has weight \text{0E29+2}
'\text{c}' has weight \text{0E29+3}

...
However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

```
'a' has weight [0E29][233D+1]
'b' has weight [0E29][233D+2]
'c' has weight [0E29][233D+3]
...
```

233D is the UCA 4.0.0 weight for character 0xA48C, which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses 3ACA, for character 0x1342E.

MySQL-Specific LDML Extensions

An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```
<collation id="nnn" name="utf8_xxx_ci" version="5.2.0">
...
</collation>
```

10.13.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

  ![Warning] Buffered warning: Unknown LDML tag: 'charsets/charset/collation/rules/aaa'

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.

- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

  ![reset]abcdefghi</reset>

  ![i]x</i>

An attempt to use the collation produces warnings:

```
mysql> SELECT _utf8'test' COLLATE utf8_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8_test_ci'
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
|---------+------|----------------------------------------|
| Error   | 1273 | Unknown collation: 'utf8_test_ci'      |
```
10.14 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See Section 5.1.7, "Server Command Options". The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the [client] group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```plaintext
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets
```

```plaintext
[client]
character-sets-dir="C:\Program Files\MySQL\MySQL Server 8.0\share\charsets"
```

- If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

  For Unicode character sets, you can define collations without recompiling by using LDML notation. See Section 10.13.4, "Adding a UCA Collation to a Unicode Character Set".

- If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.

- If your character set index file (`Index.xml`) does not contain the name for the character set, your program displays an error message:

  Character set 'charset_name' is not a compiled character set and is not specified in the '/usr/share/mysql/charsets/Index.xml' file

  To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```plaintext
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set`—that is, setting the client character set to match the system character set—should fix the problem.

1714
10.15 MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (http://www.iana.org/assignments/language-subtag-registry) such as `ja_JP` or `pt_BR`. The default value is `en_US` regardless of your system's locale setting, but you can set the value at server startup, or set the `GLOBAL` value at runtime if you have privileges sufficient to set global system variables; see Section 5.1.9.1, “System Variable Privileges”. Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| en_US           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----------------------+-------------------------+
| Friday                | January                 |
+-----------------------+-------------------------+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----------------------------------------+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----------------------------------------+
| Friday Fri January Jan                  |
+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| es_MX           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----------------------+-------------------------+
```

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----------------------+-------------------------+
```
### MySQL Server Locale Support

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

11.9 Choosing the Right Type for a Column .................................. 1798
11.10 Using Data Types from Other Database Engines ..................... 1798

MySQL supports a number of SQL data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the JSON data type. This chapter provides an overview of these data types, a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more
detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- $M$ indicates the maximum display width for integer types. For floating-point and fixed-point types, $M$ is the total number of digits that can be stored (the precision). For string types, $M$ is the maximum length. The maximum permissible value of $M$ depends on the data type.

- $D$ applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than $M-2$.

- $fsp$ applies to the `TIME`, `DATETIME`, and `TIMESTAMP` types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The $fsp$ value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Square brackets ([ and ]) indicate optional parts of type definitions.

### 11.1 Data Type Overview

#### 11.1.1 Numeric Type Overview

A summary of the numeric data types follows. For additional information about properties and storage requirements of the numeric types, see Section 11.2, “Numeric Types”, and Section 11.8, “Data Type Storage Requirements”.

$M$ indicates the maximum display width for integer types. The maximum display width is 255. Display width is unrelated to the range of values a type can contain, as described in Section 11.2, “Numeric Types”. For floating-point and fixed-point types, $M$ is the total number of digits that can be stored.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

**Warning**

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See Section 12.10, “Cast Functions and Operators”.

- **BIT[$M$]**

  A bit-value type. $M$ indicates the number of bits per value, from 1 to 64. The default is 1 if $M$ is omitted.

- **TINYINT[$M$] [UNSIGNED] [ZEROFILL]**

  A very small integer. The signed range is $-128$ to $127$. The unsigned range is $0$ to $255$.

- **BOOL, BOOLEAN**
These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+------------------------+
| IF(0, 'true', 'false') |
| false                  |
+------------------------+
mysql> SELECT IF(1, 'true', 'false');
+------------------------+
| IF(1, 'true', 'false') |
| true                   |
+------------------------+
mysql> SELECT IF(2, 'true', 'false');
+------------------------+
| IF(2, 'true', 'false') |
| true                   |
+------------------------+
```

However, the values `TRUE` and `FALSE` are merely aliases for 1 and 0, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+--------------------------------+
| IF(0 = FALSE, 'true', 'false') |
| true                           |
+--------------------------------+
mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-------------------------------+
| IF(1 = TRUE, 'true', 'false') |
| true                          |
+-------------------------------+
mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-------------------------------+
| IF(2 = TRUE, 'true', 'false') |
| false                         |
+-------------------------------+
mysql> SELECT IF(2 = FALSE, 'true', 'false');
+--------------------------------+
| IF(2 = FALSE, 'true', 'false') |
| false                          |
+--------------------------------+
```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- **SMALLINT[(M)] [UNSIGNED] [ZEROFILL]**

  A small integer. The signed range is **-32768** to **32767**. The unsigned range is **0** to **65535**.

- **MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]**
Numeric Type Overview

A medium-sized integer. The signed range is \( -8388608 \) to \( 8388607 \). The unsigned range is \( 0 \) to \( 16777215 \).

- \texttt{INT[(\( M \))] [UNSIGNED] [ZEROFILL]}

A normal-size integer. The signed range is \( -2147483648 \) to \( 2147483647 \). The unsigned range is \( 0 \) to \( 4294967295 \).

- \texttt{INTEGER[(\( M \))] [UNSIGNED] [ZEROFILL]}

This type is a synonym for \texttt{INT}.

- \texttt{BIGINT[(\( M \))] [UNSIGNED] [ZEROFILL]}

A large integer. The signed range is \( -9223372036854775808 \) to \( 9223372036854775807 \). The unsigned range is \( 0 \) to \( 18446744073709551615 \).

\texttt{SERIAL} is an alias for \texttt{BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE}.

Some things you should be aware of with respect to \texttt{BIGINT} columns:

- All arithmetic is done using signed \texttt{BIGINT} or \texttt{DOUBLE} values, so you should not use unsigned big integers larger than \( 9223372036854775807 \) (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a \texttt{BIGINT} value to a \texttt{DOUBLE}.

MySQL can handle \texttt{BIGINT} in the following cases:

- When using integers to store large unsigned values in a \texttt{BIGINT} column.
- In \texttt{MIN(col_name)} or \texttt{MAX(col_name)}, where \texttt{col_name} refers to a \texttt{BIGINT} column.
- When using operators (\(+, -, *, \) and so on) where both operands are integers.
- You can always store an exact integer value in a \texttt{BIGINT} column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The \(-, +, \) and \(*\) operators use \texttt{BIGINT} arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than \( 9223372036854775807 \).

- \texttt{DECIMAL[(\( M,[D] \))] [UNSIGNED] [ZEROFILL]}

A packed “exact” fixed-point number. \( M \) is the total number of digits (the precision) and \( D \) is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the \(-\) sign are not counted in \( M \). If \( D \) is 0, values have no decimal point or fractional part. The maximum number of digits (\( M \)) for \texttt{DECIMAL} is 65. The maximum number of supported decimals (\( D \)) is 30. If \( D \) is omitted, the default is 0. If \( M \) is omitted, the default is 10.

\texttt{UNSIGNED}, if specified, disallows negative values.

All basic calculations (\(+, -, *, /\)) with \texttt{DECIMAL} columns are done with a precision of 65 digits.

- \texttt{DEC[(\( M,[D] \))] [UNSIGNED] [ZEROFILL], NUMERIC[(\( M,[D] \))] [UNSIGNED] [ZEROFILL], FIXED[(\( M,[D] \))] [UNSIGNED] [ZEROFILL]
These types are synonyms for DECIMAL. The FIXED synonym is available for compatibility with other database systems.

- \texttt{FLOAT[(M, D)] [UNSIGNED] [ZEROFILL]}

A small (single-precision) floating-point number. Permissible values are $-3.402823466E+38$ to $-1.175494351E-38$, $0$, and $1.175494351E-38$ to $3.402823466E+38$. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

- $M$ is the total number of digits and $D$ is the number of digits following the decimal point. If $M$ and $D$ are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

- \texttt{UNSIGNED}, if specified, disallows negative values.

Using \texttt{FLOAT} might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section B.6.4.7, "Solving Problems with No Matching Rows".

- \texttt{FLOAT(p) [UNSIGNED] [ZEROFILL]}

A floating-point number. $p$ represents the precision in bits, but MySQL uses this value only to determine whether to use \texttt{FLOAT} or \texttt{DOUBLE} for the resulting data type. If $p$ is from 0 to 24, the data type becomes \texttt{FLOAT} with no $M$ or $D$ values. If $p$ is from 25 to 53, the data type becomes \texttt{DOUBLE} with no $M$ or $D$ values. The range of the resulting column is the same as for the single-precision \texttt{FLOAT} or double-precision \texttt{DOUBLE} data types described earlier in this section.

- \texttt{FLOAT(p)} syntax is provided for ODBC compatibility.

- \texttt{DOUBLE[(M, D)] [UNSIGNED] [ZEROFILL]}

A normal-size (double-precision) floating-point number. Permissible values are $-1.7976931348623157E+308$ to $-2.2250738585072014E-308$, $0$, and $2.2250738585072014E-308$ to $1.7976931348623157E+308$. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

- $M$ is the total number of digits and $D$ is the number of digits following the decimal point. If $M$ and $D$ are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

- \texttt{UNSIGNED}, if specified, disallows negative values.

- \texttt{DOUBLE PRECISION[(M, D)] [UNSIGNED] [ZEROFILL], REAL[(M, D)] [UNSIGNED] [ZEROFILL]}

These types are synonyms for \texttt{DOUBLE}. Exception: If the REAL\_AS\_FLOAT SQL mode is enabled, \texttt{REAL} is a synonym for \texttt{FLOAT} rather than \texttt{DOUBLE}.

11.1.2 Date and Time Type Overview

A summary of the temporal data types follows. For additional information about properties and storage requirements of the temporal types, see Section 11.3, "Date and Time Types", and Section 11.8, "Data Type Storage Requirements". For descriptions of functions that operate on temporal values, see Section 12.7, "Date and Time Functions".
For the **DATE** and **DATETIME** range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for **TIME**, **DATETIME**, and **TIMESTAMP** values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is **TIME**, **DATETIME**, or **TIMESTAMP**, and `fsp` is the fractional seconds precision. For example:

```sql
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any **TIMESTAMP** or **DATETIME** column in a table can have automatic initialization and updating properties.

- **DATE**
  
  A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays **DATE** values in 'YYYY-MM-DD' format, but permits assignment of values to **DATE** columns using either strings or numbers.

- **DATETIME**(fsp)
  
  A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. MySQL displays **DATETIME** values in 'YYYY-MM-DD HH:MM:SS[.fraction]' format, but permits assignment of values to **DATETIME** columns using either strings or numbers.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

  Automatic initialization and updating to the current date and time for **DATETIME** columns can be specified using **DEFAULT** and **ON UPDATE** column definition clauses, as described in Section 11.3.4, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

- **TIMESTAMP**(fsp)
  
  A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC. **TIMESTAMP** values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A **TIMESTAMP** cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” **TIMESTAMP** value.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

  The way the server handles **TIMESTAMP** definitions depends on the value of the `explicit_defaults_for_timestamp` system variable (see Section 5.1.8, “Server System Variables”).

  If `explicit_defaults_for_timestamp` is enabled, there is no automatic assignment of the **DEFAULT CURRENT_TIMESTAMP** or **ON UPDATE CURRENT_TIMESTAMP** attributes to any **TIMESTAMP** column. They must be included explicitly in the column definition. Also, any **TIMESTAMP** not explicitly declared as **NOT NULL** permits **NULL** values.

  If `explicit_defaults_for_timestamp` is disabled, the server handles **TIMESTAMP** as follows:
Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default, the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

- **TIME**(fsp)

  A time. The range is `-838:59:59.000000` to `838:59:59.000000`. MySQL displays `TIME` values in `'HH:MM:SS[.fraction]'` format, but permits assignment of values to `TIME` columns using either strings or numbers.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- **YEAR[(4)]**

  A year in four-digit format. MySQL displays `YEAR` values in `'YYYY'` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as `1901` to `2155`, and `0000`.

  For additional information about `YEAR` display format and interpretation of input values, see Section 11.3.3, "The YEAR Type".

**Note**

MySQL 8.0 does not support the `YEAR(2)` data type permitted in older versions of MySQL. For instructions on converting to `YEAR(4)`, see YEAR(2) Limitations and Migrating to YEAR(4) in MySQL 5.7 Reference Manual.

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

### 11.1.3 String Type Overview

A summary of the string data types follows. For additional information about properties and storage requirements of the string types, see Section 11.4, “String Types”, and Section 11.8, “Data Type Storage Requirements”.

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See Section 13.1.20.8, “Silent Column Specification Changes”.

MySQL interprets length specifications in character column definitions in character units. This applies to `CHAR`, `VARCHAR`, and the `TEXT` types.

Column definitions for character string types `CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can specify the column character set and collation:
• **CHARACTER SET** specifies the character set. If desired, a collation for the character set can be specified with the **COLLATE** attribute, along with any other attributes. For example:

```sql
CREATE TABLE t
(
    c1 VARCHAR(20) CHARACTER SET utf8,
    c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive collation.

The rules for assigning the character set and collation when either or both of **CHARACTER SET** and the **COLLATE** attribute are missing are described in Section 10.3.5, “Column Character Set and Collation”. **CHARSET** is a synonym for **CHARACTER SET**.

• Specifying the **CHARACTER SET binary** attribute for a character string data type causes the column to be created as the corresponding binary string data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
(
    c1 VARCHAR(10) CHARACTER SET binary,
    c2 TEXT CHARACTER SET binary,
    c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```sql
CREATE TABLE t
(
    c1 VARBINARY(10),
    c2 BLOB,
    c3 ENUM('a','b','c') CHARACTER SET binary
);
```

• The **BINARY** attribute is shorthand for specifying the table default character set and the binary (_bin) collation of that character set. In this case, comparison and sorting are based on numeric character code values.

• The **ASCII** attribute is shorthand for **CHARACTER SET latin1**.

• The **UNICODE** attribute is shorthand for **CHARACTER SET ucs2**.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary (_bin) collation or the **BINARY** attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see Chapter 10, **Character Sets, Collations, Unicode**.

• ```sql
[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]```
A fixed-length string that is always right-padded with spaces to the specified length when stored. \( M \) represents the column length in characters. The range of \( M \) is 0 to 255. If \( M \) is omitted, the length is 1.

**Note**

Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

`CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. See Section 10.3.7, “The National Character Set”.

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `' '` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. \( M \) represents the maximum column length in characters. The range of \( M \) is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See Section C.10.4, “Limits on Table Column Count and Row Size”.

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

**Note**

MySQL follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. See Section 10.3.7, “The National Character Set”. `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY[(M)]`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. An optional length \( M \) represents the column length in bytes. If omitted, \( M \) defaults to 1.

- `VARBINARY(M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. \( M \) represents the maximum column length in bytes.

- `TINYBLOB`
String Type Overview

A **BLOB** column with a maximum length of 255 \(2^8 - 1\) bytes. Each **TINYBLOB** value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **TINYTEXT** [CHARACTER SET charset_name] [COLLATE collation_name]
  A **TEXT** column with a maximum length of 255 \(2^8 - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each **TINYTEXT** value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **BLOB\((M)\)**
  A **BLOB** column with a maximum length of 65,535 \(2^{16} - 1\) bytes. Each **BLOB** value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length \(M\) can be given for this type. If this is done, MySQL creates the column as the smallest **BLOB** type large enough to hold values \(M\) bytes long.

- **TEXT\((M)\)** [CHARACTER SET charset_name] [COLLATE collation_name]
  A **TEXT** column with a maximum length of 65,535 \(2^{16} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each **TEXT** value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length \(M\) can be given for this type. If this is done, MySQL creates the column as the smallest **TEXT** type large enough to hold values \(M\) characters long.

- **MEDIUMBLOB**
  A **BLOB** column with a maximum length of 16,777,215 \(2^{24} - 1\) bytes. Each **MEDIUMBLOB** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **MEDIUMTEXT** [CHARACTER SET charset_name] [COLLATE collation_name]
  A **TEXT** column with a maximum length of 16,777,215 \(2^{24} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each **MEDIUMTEXT** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **LONGBLOB**
  A **BLOB** column with a maximum length of 4,294,967,295 or 4GB \(2^{32} - 1\) bytes. The effective maximum length of **LONGBLOB** columns depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGBLOB** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **LONGTEXT** [CHARACTER SET charset_name] [COLLATE collation_name]
  A **TEXT** column with a maximum length of 4,294,967,295 or 4GB \(2^{32} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of **LONGTEXT** columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGTEXT** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **ENUM('value1','value2',...)** [CHARACTER SET charset_name] [COLLATE collation_name]
  An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special '' error value. **ENUM** values are represented internally as integers.
An `ENUM` column can have a maximum of 65,535 distinct elements.

The maximum supported length of an individual `ENUM` element is \( M \leq 255 \) and \( (M \times w) \leq 1020 \), where \( M \) is the element literal length and \( w \) is the number of bytes required for the maximum-length character in the character set.

- \( \text{SET}(\text{value1}'\text{, value2}',...) \) [\text{CHARACTER SET} charset\_name] [\text{COLLATE} collation\_name]

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... SET values are represented internally as integers.

A `SET` column can have a maximum of 64 distinct members.

The maximum supported length of an individual `SET` element is \( M \leq 255 \) and \( (M \times w) \leq 1020 \), where \( M \) is the element literal length and \( w \) is the number of bytes required for the maximum-length character in the character set.

## 11.2 Numeric Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and the keywords `DEC` and `FIXED` are synonyms for `DECIMAL`. MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a nonstandard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a nonstandard variation), unless the `REAL_AS_FLOAT` SQL mode is enabled.

The `BIT` data type stores bit values and is supported for `MyISAM`, `MEMORY`, `InnoDB`, and `NDB` tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see Section 11.2.6, “Out-of-Range and Overflow Handling”.

For information about numeric type storage requirements, see Section 11.8, “Data Type Storage Requirements”.

The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see Section 12.6.1, “Arithmetic Operators”.

### 11.2.1 Integer Types (Exact Value) - `INTEGER`, `INT`, `SMALLINT`, `TINYINT`, `MEDIUMINT`, `BIGINT`

MySQL supports the SQL standard integer types `INTEGER` (or `INT`) and `SMALLINT`. As an extension to the standard, MySQL also supports the integer types `TINYINT`, `MEDIUMINT`, and `BIGINT`. The following table shows the required storage and range for each integer type.

<table>
<thead>
<tr>
<th>Type</th>
<th>Storage (Bytes)</th>
<th>Minimum Value Signed</th>
<th>Minimum Value Unsigned</th>
<th>Maximum Value Signed</th>
<th>Maximum Value Unsigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1</td>
<td>-128</td>
<td>0</td>
<td>127</td>

### 11.2.2 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The DECIMAL and NUMERIC types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, NUMERIC is implemented as DECIMAL, so the following remarks about DECIMAL apply equally to NUMERIC.

MySQL stores DECIMAL values in binary format. See Section 12.25, “Precision Math”.

In a DECIMAL column declaration, the precision and scale can be (and usually is) specified; for example:

```sql
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that DECIMAL(5,2) be able to store any value with five digits and two decimals, so values that can be stored in the salary column range from $-999.99$ to $999.99$.

In standard SQL, the syntax DECIMAL\((M)\) is equivalent to DECIMAL\((M,0)\). Similarly, the syntax DECIMAL is equivalent to DECIMAL\((M,0)\), where the implementation is permitted to decide the value of \(M\). MySQL supports both of these variant forms of DECIMAL syntax. The default value of \(M\) is 10.

If the scale is 0, DECIMAL values contain no decimal point or fractional part.

The maximum number of digits for DECIMAL is 65, but the actual range for a given DECIMAL column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

### 11.2.3 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The FLOAT and DOUBLE types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For FLOAT, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword FLOAT in parentheses; that is, FLOAT\((p)\). MySQL also supports this optional precision specification, but the precision value in FLOAT\((p)\) is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision FLOAT column. A precision from 24 to 53 results in an 8-byte double-precision DOUBLE column.

MySQL permits a nonstandard syntax: FLOAT\((M,D)\) or REAL\((M,D)\) or DOUBLE PRECISION\((M,D)\). Here, \((M,D)\) means than values can be stored with up to \(M\) digits in total, of which \(D\) digits may be after the decimal point. For example, a column defined as FLOAT\((7,4)\) will look like $-999.9999$ when displayed.
MySQL performs rounding when storing values, so if you insert 999.00009 into a `FLOAT(7,4)` column, the approximate result is 999.0001.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see Section B.6.4.8, “Problems with Floating-Point Values”.

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

### 11.2.4 Bit-Value Type - BIT

The `BIT` data type is used to store bit values. A type of `BIT(M)` enables storage of $M$-bit values. $M$ can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. `value` is a binary value written using zeros and ones. For example, `b'111'` and `b'10000000'` represent 7 and 128, respectively. See Section 9.1.5, “Bit-Value Literals”.

If you assign a value to a `BIT(M)` column that is less than $M$ bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

**NDB Cluster.** The maximum combined size of all `BIT` columns used in a given NDB table must not exceed 4096 bits.

### 11.2.5 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used or not is up to the application.)

The display width does not constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of $-32768$ to $32767$, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) attribute `ZEROFILL`, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of 5 is retrieved as `0005`.

#### Note

The `ZEROFILL` attribute is ignored when a column is involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) attribute `UNSIGNED`. Unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the
Out-of-Range and Overflow Handling

column. For example, if an INT column is UNSIGNED, the size of the column’s range is the same but its endpoints shift from \(-2147483648\) and \(2147483647\) up to \(0\) and \(4294967295\).

Floating-point and fixed-point types also can be UNSIGNED. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify ZEROFILL for a numeric column, MySQL automatically adds the UNSIGNED attribute to the column.

Integer or floating-point data types can have the additional attribute AUTO_INCREMENT. When you insert a value of NULL into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is \(\text{value}+1\), where \(\text{value}\) is the largest value for the column currently in the table. (AUTO_INCREMENT sequences begin with 1.)

Storing 0 into an AUTO_INCREMENT column has the same effect as storing NULL, unless the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled.

Inserting NULL to generate AUTO_INCREMENT values requires that the column be declared NOT NULL. If the column is declared NULL, inserting NULL stores a NULL. When you insert any other value into an AUTO_INCREMENT column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

Negative values for AUTO_INCREMENT columns are not supported.

CHECK constraints cannot refer to columns that have the AUTO_INCREMENT attribute, nor can the AUTO_INCREMENT attribute be added to existing columns that are used in CHECK constraints.

11.2.6 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Suppose that a table \(t1\) has this definition:

```
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out of range error occurs:

```
mysql> SET sql_mode = 'TRADITIONAL';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
mysql> SELECT * FROM t1;
Empty set (0.00 sec)
```
With strict SQL mode not enabled, clipping with warnings occurs:

```sql
mysql> SET sql_mode = '';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1264</td>
<td>Out of range value for column 'i1' at row 1</td>
</tr>
<tr>
<td>Warning</td>
<td>1264</td>
<td>Out of range value for column 'i2' at row 1</td>
</tr>
</tbody>
</table>
+---------+------+---------------------------------------------+

mysql> SELECT * FROM t1;
+------+------+
| i1   | i2   |
+------+------+
| 127  | 255  |
+------+------+
```

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for `ALTER TABLE`, `LOAD DATA`, `UPDATE`, and multiple-row `INSERT` statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending on whether the table is a transactional table and other factors. For details, see Section 5.1.11, “Server SQL Modes”.

Overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression produces an error:

```sql
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned:

```sql
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-------------------------------------------+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-------------------------------------------+
|                       9223372036854775808 |
+-------------------------------------------+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```sql
mysql> SELECT 9223372036854775807.0 + 1;
+---------------------------+
| 9223372036854775807.0 + 1 |
+---------------------------+
|     9223372036854775808.0 |
+---------------------------+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```sql
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:
If the result of such an operation is used to update an UNSIGNED integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if NO_UNSIGNED_SUBTRACTION is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

11.3 Date and Time Types

The date and time types for representing temporal values are DATE, TIME, DATETIME, TIMESTAMP, and YEAR. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The TIMESTAMP type has special automatic updating behavior, described later. For temporal type storage requirements, see Section 11.8, “Data Type Storage Requirements”.

Keep in mind these general considerations when working with date and time types:

• MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see Section 9.1.3, “Date and Time Literals”. It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.

• Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, '98-09-04'), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, '09-04-98', '04-09-98').

• Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  • Year values in the range 70–99 are converted to 1970–1999.
  • Year values in the range 00–69 are converted to 2000–2069.

See also Section 11.3.7, “Two-Digit Years in Dates”.

• Conversion of values from one temporal type to another occurs according to the rules in Section 11.3.6, “Conversion Between Date and Time Types”.

• MySQL automatically converts a date or time value to a number if the value is used in a numeric context and vice versa.

• By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range TIME values are clipped to the appropriate endpoint of the TIME range.

• By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See Section 5.1.11, “Server SQL Modes”.) You can get MySQL to accept certain dates, such as '2009-11-31', by enabling the ALLOW_INVALID_DATES SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
The DATE, DATETIME, and TIMESTAMP Types

- MySQL permits you to store dates where the day or month and day are zero in a DATE or DATETIME column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. If you store dates such as these, you should not expect to get correct results for functions such as DATE_SUB() or DATE_ADD() that require complete dates. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE mode.

- MySQL permits you to store a "zero" value of '0000-00-00' as a "dummy date." This is in some cases more convenient than using NULL values, and uses less data and index space. To disallow '0000-00-00', enable the NO_ZERO_DATE mode.

- "Zero" date or time values used through Connector/ODBC are converted automatically to NULL because ODBC cannot handle such values.

The following table shows the format of the "zero" value for each type. The "zero" values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write. For temporal types that include a date part (DATE, DATETIME, and TIMESTAMP), use of these values produces warnings if the NO_ZERO_DATE SQL mode is enabled.

11.3.1 The DATE, DATETIME, and TIMESTAMP Types

The DATE, DATETIME, and TIMESTAMP types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes DATE, DATETIME, and TIMESTAMP values in several formats, described in Section 9.1.3, "Date and Time Literals". For the DATE and DATETIME range descriptions, "supported" means that although earlier values might work, there is no guarantee.

The DATE type is used for values with a date part but no time part. MySQL retrieves and displays DATE values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

The DATETIME type is used for values that contain both date and time parts. MySQL retrieves and displays DATETIME values in 'YYYY-MM-DD HH:MM:SS' format. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The TIMESTAMP data type is used for values that contain both date and time parts. TIMESTAMP has a range of '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC.

A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, any fractional part in a value inserted into a DATETIME or TIMESTAMP column is stored rather than discarded. With the fractional part included, the format for these values is 'YYYY-MM-DD HH:MM:SS[.fraction]', the range for DATETIME values is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999', and the range for TIMESTAMP values is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999'. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.3.5, "Fractional Seconds in Time Values".
The **TIMESTAMP** and **DATETIME** data types offer automatic initialization and updating to the current date and time. For more information, see Section 11.3.4, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

MySQL converts **TIMESTAMP** values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as **DATETIME**.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a **TIMESTAMP** value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable. For more information, see Section 5.1.13, “MySQL Server Time Zone Support”.

Invalid **DATE**, **DATETIME**, or **TIMESTAMP** values are converted to the “zero” value of the appropriate type (`'0000-00-00'` or `'0000-00-00 00:00:00'`).

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a "relaxed" format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the `:`; but is interpreted as the year `'2010-11-12'` if used in a date context. The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a valid month.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`. See Section 5.1.11, “Server SQL Modes”, for more information.

- MySQL does not accept **TIMESTAMP** values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value `'0000-00-00 00:00:00'`.

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range `00–69` are converted to `2000-2069`.
  - Year values in the range `70–99` are converted to `1970–1999`.

See also Section 11.3.7, “Two-Digit Years in Dates”.

### 11.3.2 The **TIME** Type

MySQL retrieves and displays **TIME** values in `'HH:MM:SS'` format (or `'HHH:MM:SS'` format for large hours values). **TIME** values may range from `'−838:59:59'` to `'838:59:59'`. The hours part may be so large because the **TIME** type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes **TIME** values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See Section 9.1.3, “Date and Time Literals”. For
information about fractional seconds support in MySQL, see Section 11.3.5, “Fractional Seconds in Time Values”. In particular, any fractional part in a value inserted into a `TIME` column is stored rather than discarded. With the fractional part included, the range for `TIME` values is `'-838:59:59.000000'` to `'838:59:59.000000'`.

Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, `'11:12'` means `'11:12:00'`, not `'00:11:12'`. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o’clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`.

The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, `'−850:00:00'` and `'850:00:00'` are converted to `'−838:59:59'` and `'838:59:59'`. Invalid `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a valid `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See Section 5.1.11, “Server SQL Modes”.

11.3.3 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` or `YEAR(4)` and has a display width of four characters.

MySQL 8.0 does not support the `YEAR(2)` data type permitted in older versions of MySQL. For instructions on converting to `YEAR(4)`, see YEAR(2) Limitations and Migrating to YEAR(4) in MySQL 5.7 Reference Manual.

MySQL displays `YEAR` values in `YYYY` format, with a range of `1901` to `2155`, or `0000`.

You can specify input `YEAR` values in a variety of formats:

- As a 4-digit number in the range `1901` to `2155`.
- As a 4-digit string in the range `'1901'` to `'2155'`.
- As a 1- or 2-digit number in the range `1` to `99`. MySQL converts values in the ranges `1` to `69` and `70` to `99` to `YEAR` values in the ranges `2001` to `2069` and `1970` to `1999`.
- As a 1- or 2-digit string in the range `'0'` to `'99'`. MySQL converts values in the ranges `'0'` to `'69'` and `'70'` to `'99'` to `YEAR` values in the ranges `2000` to `2069` and `1970` to `1999`.
- The result of inserting a numeric `0` has a display value of `0000` and an internal value of `0000`. To insert zero and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.
- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()`.

MySQL converts invalid `YEAR` values to `0000`.

See also Section 11.3.7, “Two-Digit Years in Dates”.

11.3.4 Automatic Initialization and Updating for TIMESTAMP and DATETIME
**TIMESTAMP** and **DATETIME** columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any **TIMESTAMP** or **DATETIME** column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to **CURRENT_TIMESTAMP**).

In addition, if the **explicit_defaults_for_timestamp** system variable is disabled, you can initialize or update any **TIMESTAMP** (but not **DATETIME**) column to the current date and time by assigning it a **NULL** value, unless it has been defined with the **NULL** attribute to permit **NULL** values.

To specify automatic properties, use the **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for **CURRENT_TIMESTAMP** have the same meaning as **CURRENT_TIMESTAMP**. These are **CURRENT_TIMESTAMP()**, **NOW()**, **LOCALTIME**, **LOCALTIME()**, **LOCALTIMESTAMP**, and **LOCALTIMESTAMP()**.

Use of **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** is specific to **TIMESTAMP** and **DATETIME**. The **DEFAULT** clause also can be used to specify a constant (nonautomatic) default value; for example, **DEFAULT 0** or **DEFAULT '2000-01-01 00:00:00'**.

**Note**

The following examples use **DEFAULT 0**, a default that can produce warnings or errors depending on whether strict SQL mode or the **NO_ZERO_DATE** SQL mode is enabled. Be aware that the **TRADITIONAL** SQL mode includes strict mode and **NO_ZERO_DATE**. See Section 5.1.11, “Server SQL Modes”.

**TIMESTAMP** or **DATETIME** column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- With both **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP**, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

  ```sql
  CREATE TABLE t1 (  
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
    dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
  );
  ```

- With a **DEFAULT** clause but no **ON UPDATE CURRENT_TIMESTAMP** clause, the column has the given default value and is not automatically updated to the current timestamp.

  The default depends on whether the **DEFAULT** clause specifies **CURRENT_TIMESTAMP** or a constant value. With **CURRENT_TIMESTAMP**, the default is the current timestamp.

  ```sql
  CREATE TABLE t1 (  
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  ```
dt DATETIME DEFAULT CURRENT_TIMESTAMP
);

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

CREATE TABLE t1 ( 
  ts TIMESTAMP DEFAULT 0, 
  dt DATETIME DEFAULT 0 
);

• With an ON UPDATE CURRENT_TIMESTAMP clause and a constant DEFAULT clause, the column is automatically updated to the current timestamp and has the given constant default value.

CREATE TABLE t1 ( 
  ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP, 
  dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP 
);

• With an ON UPDATE CURRENT_TIMESTAMP clause but no DEFAULT clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

The default in this case is type dependent. TIMESTAMP has a default of 0 unless defined with the NULL attribute, in which case the default is NULL.

CREATE TABLE t1 ( 
  ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,     -- default 0 
  ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);

DATETIME has a default of NULL unless defined with the NOT NULL attribute, in which case the default is 0.

CREATE TABLE t1 ( 
  dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP,         -- default NULL 
  dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
);

TIMESTAMP and DATETIME columns have no automatic properties unless they are specified explicitly, with this exception: If the explicit_defaults_for_timestamp system variable is disabled, the first TIMESTAMP column has both DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP if neither is specified explicitly. To suppress automatic properties for the first TIMESTAMP column, use one of these strategies:

• Enable the explicit_defaults_for_timestamp system variable. In this case, the DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses that specify automatic initialization and updating are available, but are not assigned to any TIMESTAMP column unless explicitly included in the column definition.

• Alternatively, if explicit_defaults_for_timestamp is disabled, do either of the following:
  • Define the column with a DEFAULT clause that specifies a constant default value.
  • Specify the NULL attribute. This also causes the column to permit NULL values, which means that you cannot assign the current timestamp by setting the column to NULL. Assigning NULL sets the column to NULL, not the current timestamp. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().
Consider these table definitions:

```sql
CREATE TABLE t1 {
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 {
  ts1 TIMESTAMP NULL,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 {
  ts1 TIMESTAMP NULL DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first `TIMESTAMP` column has no automatic initialization or updating.
- The tables differ in how the `ts1` column handles `NULL` values. For `t1`, `ts1` is `NOT NULL` and assigning it a value of `NULL` sets it to the current timestamp. For `t2` and `t3`, `ts1` permits `NULL` and assigning it a value of `NULL` sets it to `NULL`.
- `t2` and `t3` differ in the default value for `ts1`. For `t2`, `ts1` is defined to permit `NULL`, so the default is also `NULL` in the absence of an explicit `DEFAULT` clause. For `t3`, `ts1` permits `NULL` but has an explicit default of 0.

If a `TIMESTAMP` or `DATETIME` column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```sql
CREATE TABLE t1 {
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
};
```

This is not permitted:

```sql
CREATE TABLE t1 {
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP(3)
};
```

### TIMESTAMP Initialization and the NULL Attribute

If the `explicit_defaults_for_timestamp` system variable is disabled, `TIMESTAMP` columns by default are `NOT NULL`, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. To permit a `TIMESTAMP` column to contain `NULL`, explicitly declare it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is invalid.) If a `TIMESTAMP` column permits `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that permit `NULL` values:

```sql
CREATE TABLE t {
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
};
```
A `TIMESTAMP` column that permits `NULL` values does not take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```sql
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```sql
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```sql
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
INSERT INTO t1 VALUES (NOW());
```

If the `explicit_defaults_for_timestamp` system variable is enabled, `TIMESTAMP` columns permit `NULL` values only if declared with the `NULL` attribute. Also, `TIMESTAMP` columns do not permit assigning `NULL` to assign the current timestamp, whether declared with the `NULL` or `NOT NULL` attribute. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.

### 11.3.5 Fractional Seconds in Time Values

MySQL 8.0 has fractional seconds support for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

  ```sql
  CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
  ```

  The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a `TIME`, `DATE`, or `TIMESTAMP` value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding. Consider a table created and populated as follows:

  ```sql
  CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2) );
  INSERT INTO fractest VALUES
  ```
Conversion Between Date and Time Types

The temporal values are inserted into the table with rounding:

```
mysql> SELECT * FROM fractest;
+-------------+------------------------+------------------------+
| c1          | c2                     | c3                     |
| 17:51:04.78 | 2018-09-08 17:51:04.78 | 2018-09-08 17:51:04.78 |
+-------------+------------------------+------------------------+
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard.

To insert the values with truncation instead, enable the `TIME_TRUNCATE_FRACTIONAL` SQL mode:

```
SET @@sql_mode = sys.list_add(@@sql_mode, 'TIME_TRUNCATE_FRACTIONAL');
```

With that SQL mode enabled, the temporal values are inserted with truncation:

```
mysql> SELECT * FROM fractest;
+-------------+------------------------+------------------------+
| c1          | c2                     | c3                     |
| 17:51:04.77 | 2018-09-08 17:51:04.77 | 2018-09-08 17:51:04.77 |
+-------------+------------------------+------------------------+
```

• Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, `NOW()` with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.

• Syntax for temporal literals produces temporal values: `DATE 'str'`, `TIME 'str'`, and `TIMESTAMP 'str'`, and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See Standard SQL and ODBC Date and Time Literals

### 11.3.6 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than 1970 UTC or later than `2038-01-19 03:14:07` UTC. This means that a date such as `'1968-01-01'`, while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

• Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of `'00:00:00'` because the `DATE` value contains no time information.

• Conversion to a `TIME` value is not useful; the result is `'00:00:00'`.

Conversion of `DATETIME` and `TIMESTAMP` values:

• Conversion to a `DATE` value takes fractional seconds into account and rounds the time part. For example, `'1999-12-31 23:59:59.499'` becomes `'1999-12-31'`, whereas `'1999-12-31 23:59:59.500'` becomes `'2000-01-01'`. 

For conversion of \texttt{TIME} values to other temporal types, the value of \texttt{CURRENT\_DATE()} is used for the date part. The \texttt{TIME} is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01', \texttt{TIME} values of '12:00:00', '24:00:00', and '-12:00:00', when converted to \texttt{DATETIME} or \texttt{TIMESTAMP} values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

Conversion of \texttt{TIME} to \texttt{DATE} is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.

Explicit conversion can be used to override implicit conversion. For example, in comparison of \texttt{DATE} and \texttt{DATETIME} values, the \texttt{DATE} value is coerced to the \texttt{DATETIME} type by adding a time part of '00:00:00'. To perform the comparison by ignoring the time part of the \texttt{DATETIME} value instead, use the \texttt{CAST()} function in the following way:

\[
\text{date\_col} = \text{CAST(datetime\_col AS DATE)}
\]

Conversion of \texttt{TIME} and \texttt{DATETIME} values to numeric form (for example, by adding \texttt{+0}) depends on whether the value contains a fractional seconds part. \texttt{TIME(N)} or \texttt{DATETIME(N)} is converted to integer when \textit{N} is 0 (or omitted) and to a \texttt{DECIMAL} value with \textit{N} decimal digits when \textit{N} is greater than 0:

mysql> \text{SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;}

+-----------+-------------+--------------+
<table>
<thead>
<tr>
<th>CURTIME()</th>
<th>CURTIME()+0</th>
<th>CURTIME(3)+0</th>
</tr>
</thead>
<tbody>
<tr>
<td>09:28:00</td>
<td>92800</td>
<td>92800.887</td>
</tr>
</tbody>
</table>
+-----------+-------------+--------------+

mysql> \text{SELECT NOW(), NOW()+0, NOW(3)+0;}

+---------------------+----------------+--------------------+
<table>
<thead>
<tr>
<th>NOW()</th>
<th>NOW()+0</th>
<th>NOW(3)+0</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-08-15 09:28:00</td>
<td>20120815092800</td>
<td>20120815092800.889</td>
</tr>
</tbody>
</table>
+---------------------+----------------+--------------------+

\section*{11.3.7 Two-Digit Years in Dates}

Date values with two-digit years are ambiguous because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For \texttt{DATETIME}, \texttt{DATE}, and \texttt{TIMESTAMP} types, MySQL interprets dates specified with ambiguous year values using these rules:

\begin{itemize}
  \item Year values in the range 00–69 are converted to 2000–2069.
  \item Year values in the range 70–99 are converted to 1970–1999.
\end{itemize}

For \texttt{YEAR}, the rules are the same, with this exception: A numeric 00 inserted into \texttt{YEAR(4)} results in 0000 rather than 2000. To specify zero for \texttt{YEAR(4)} and have it be interpreted as 2000, specify it as a string '0' or '00'.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing four-digit year values.
ORDER BY properly sorts YEAR values that have two-digit years.

Some functions like MIN() and MAX() convert a YEAR to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the YEAR to four-digit year format.

11.4 String Types

The string types are CHAR, VARCHAR, BINARY, VARBINARY, BLOB, TEXT, ENUM, and SET. This section describes how these types work and how to use them in your queries. For string type storage requirements, see Section 11.8, “Data Type Storage Requirements”.

11.4.1 The CHAR and VARCHAR Types

The CHAR and VARCHAR types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The CHAR and VARCHAR types are declared with a length that indicates the maximum number of characters you want to store. For example, CHAR(30) can hold up to 30 characters.

The length of a CHAR column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When CHAR values are stored, they are right-padded with spaces to the specified length. When CHAR values are retrieved, trailing spaces are removed unless the PAD_CHAR_TO_FULL_LENGTH SQL mode is enabled.

Values in VARCHAR columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a VARCHAR is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See Section C.10.4, “Limits on Table Column Count and Row Size”.

In contrast to CHAR, VARCHAR values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a CHAR or VARCHAR column that exceeds the column’s maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.11, “Server SQL Modes”.

For VARCHAR columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For CHAR columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

VARCHAR values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between CHAR and VARCHAR by showing the result of storing various string values into CHAR(4) and VARCHAR(4) columns (assuming that the column uses a single-byte character set such as latin1).

<table>
<thead>
<tr>
<th>Value</th>
<th>CHAR(4)</th>
<th>Storage Required</th>
<th>VARCHAR(4)</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>''</td>
<td>''</td>
<td>4 bytes</td>
<td>''</td>
<td>1 byte</td>
</tr>
<tr>
<td>'ab'</td>
<td>'ab '</td>
<td>4 bytes</td>
<td>'ab'</td>
<td>3 bytes</td>
</tr>
<tr>
<td>'abcd'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
</tbody>
</table>
The CHAR and VARCHAR Types

<table>
<thead>
<tr>
<th>Value</th>
<th>CHAR(4)</th>
<th>Storage Required</th>
<th>VARCHAR(4)</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>'abcdefgh'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
</tbody>
</table>

The values shown as stored in the last row of the table apply only when not using strict mode; if MySQL is running in strict mode, values that exceed the column length are not stored, and an error results.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

If a given value is stored into the CHAR(4) and VARCHAR(4) columns, the values retrieved from the columns are not always the same because trailing spaces are removed from CHAR columns upon retrieval. The following example illustrates this difference:

```sql
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab  ', 'ab  ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+---------------------+---------------------+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
+---------------------+---------------------+
| (ab  )              | (ab)                |
+---------------------+---------------------+
1 row in set (0.06 sec)
```

Values in CHAR and VARCHAR columns are sorted and compared according to the character set collation assigned to the column.

Most MySQL collations have a pad attribute of PAD SPACE. The exceptions are Unicode collations based on UCA 9.0.0 and higher, which have a pad attribute of NO PAD. (see Section 10.10.1, “Unicode Character Sets”).

To determine the pad attribute for a collation, use the INFORMATION_SCHEMA COLLATIONS table, which has a PAD_ATTRIBUTE column.

The pad attribute determines how trailing spaces are treated for comparison of nonbinary strings (CHAR, VARCHAR, and TEXT values). NO PAD collations treat spaces at the end of strings like any other character. For PAD SPACE collations, trailing spaces are insignificant in comparisons; strings are compared without regard to any trailing spaces. “Comparison” in this context does not include the LIKE pattern-matching operator, for which trailing spaces are significant. For example:

```sql
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO names VALUES ('Monty');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT myname = 'Monty', myname = 'Monty  ' FROM names;
+------------------+--------------------+
| myname = 'Monty' | myname = 'Monty  ' |
+------------------+--------------------+
|                1 |                  1 |
+------------------+--------------------+
1 row in set (0.00 sec)

mysql> SELECT myname LIKE 'Monty', myname LIKE 'Monty  ' FROM names;
```
This is true for all MySQL versions, and is not affected by the server SQL mode.

For more information about MySQL character sets and collations, see Chapter 10, *Character Sets, Collations, Unicode*. For additional information about storage requirements, see Section 11.8, “Data Type Storage Requirements”.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

### 11.4.2 The BINARY and VARBINARY Types

The **BINARY** and **VARBINARY** types are similar to **CHAR** and **VARCHAR**, except that they contain binary strings rather than nonbinary strings. That is, they contain byte strings rather than character strings. This means they have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for **BINARY** and **VARBINARY** as it is for **CHAR** and **VARCHAR**, except that the length for **BINARY** and **VARBINARY** is a length in bytes rather than in characters.

The **BINARY** and **VARBINARY** data types are distinct from the **CHAR BINARY** and **VARCHAR BINARY** data types. For the latter types, the **BINARY** attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary (\_bin) collation for the column character set to be used, and the column itself contains nonbinary character strings rather than binary byte strings. For example, **CHAR(5) BINARY** is treated as **CHAR(5) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin**, assuming that the default character set is **utf8mb4**. This differs from **BINARY(5)**, which stores 5-bytes binary strings that have the binary character set and collation. For information about differences between binary strings and binary collations for nonbinary strings, see Section 10.8.5, “The binary Collation Compared to \_bin Collations”.

If strict SQL mode is not enabled and you assign a value to a **BINARY** or **VARBINARY** column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.11, “Server SQL Modes”.

When **BINARY** values are stored, they are right-padded with the pad value to the specified length. The pad value is 0x00 (the zero byte). Values are right-padded with 0x00 on insert, and no trailing bytes are removed on select. All bytes are significant in comparisons, including **ORDER BY** and **DISTINCT** operations. 0x00 bytes and spaces are different in comparisons, with 0x00 < space.

Example: For a **BINARY(3)** column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a\0\0' when inserted. Both inserted values remain unchanged when selected.

For **VARBINARY**, there is no padding on insert and no bytes are stripped on select. All bytes are significant in comparisons, including **ORDER BY** and **DISTINCT** operations. 0x00 bytes and spaces are different in comparisons, with 0x00 < space.
For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a\0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the BINARY data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how 0x00-padding of BINARY values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)
mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)
mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+--------+---------+-------------+
<table>
<thead>
<tr>
<th>HEX(c)</th>
<th>c = 'a'</th>
<th>c = 'a\0\0'</th>
</tr>
</thead>
<tbody>
<tr>
<td>610000</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
+--------+---------+-------------+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use VARBINARY or one of the BLOB data types instead.

### 11.4.3 The BLOB and TEXT Types

A BLOB is a binary large object that can hold a variable amount of data. The four BLOB types are TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB. These differ only in the maximum length of the values they can hold. The four TEXT types are TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT. These correspond to the four BLOB types and have the same maximum lengths and storage requirements. See Section 11.8, “Data Type Storage Requirements”.

BLOB values are treated as binary strings (byte strings). They have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. TEXT values are treated as nonbinary strings (character strings). They have a character set other than binary, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a BLOB or TEXT column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.11, “Server SQL Modes”.

Truncation of excess trailing spaces from values to be inserted into TEXT columns always generates a warning, regardless of the SQL mode.

For TEXT and BLOB columns, there is no padding on insert and no bytes are stripped on select.

If a TEXT column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for BLOB columns.

In most respects, you can regard a BLOB column as a VARBINARY column that can be as large as you like. Similarly, you can regard a TEXT column as a VARCHAR column. BLOB and TEXT differ from VARBINARY and VARCHAR in the following ways:
The ENUM Type

- For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See Section 8.3.5, “Column Indexes”.

- BLOB and TEXT columns cannot have DEFAULT values.

If you use the BINARY attribute with a TEXT data type, the column is assigned the binary (_bin) collation of the column character set.

LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because BLOB and TEXT values can be extremely long, you might encounter some constraints in using them:

- Only the first max_sort_length bytes of the column are used when sorting. The default value of max_sort_length is 1024. You can make more bytes significant in sorting or grouping by increasing the value of max_sort_length at server startup or runtime. Any client can change the value of its session max_sort_length variable:

```sql
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
-> ORDER BY comment;
```

- Instances of BLOB or TEXT columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the MEMORY storage engine does not support those data types (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Use of disk incurs a performance penalty, so include BLOB or TEXT columns in the query result only if they are really needed. For example, avoid using SELECT *.

- The maximum size of a BLOB or TEXT object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the max_allowed_packet variable, but you must do so for both the server and your client program. For example, both mysql and mysqldump enable you to change the client-side max_allowed_packet value. See Section 5.1.1, “Configuring the Server”, Section 4.5.1, “mysql — The MySQL Command-Line Client”, and Section 4.5.4, “mysqldump — A Database Backup Program”. You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see Section 11.8, “Data Type Storage Requirements”.

Each BLOB or TEXT value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in BLOB or TEXT columns. You may find MySQL's string handling functions useful for working with such data. See Section 12.5, “String Functions”. For security and other reasons, it is usually preferable to do so using application code rather than giving application users the FILE privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (http://forums.mysql.com/).

11.4.4 The ENUM Type

An ENUM is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time. It has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See Section 11.8, “Data Type Storage Requirements” for the storage requirements for ENUM types.
The ENUM Type

• Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

• If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in Enumeration Limitations.

• Using ENUM columns in ORDER BY clauses requires extra care, as explained in Enumeration Sorting.

Creating and Using ENUM Columns

Index Values for Enumeration Literals

Empty or NULL Enumeration Values

Enumeration Sorting

Enumeration Limitations

Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an ENUM column like this:

```sql
CREATE TABLE shirts (
    name VARCHAR(40),
    size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'), ('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+---------+--------+
| name    | size   |
+---------+--------+
| t-shirt | medium |
+---------+--------+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of 'medium' would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string 'medium' in a VARCHAR column.

Index Values for Enumeration Literals

Each enumeration value has an index:

• The elements listed in the column specification are assigned index numbers, beginning with 1.

• The index value of the empty string error value is 0. This means that you can use the following SELECT statement to find rows into which invalid ENUM values were assigned:

  ```sql
  mysql> SELECT * FROM tbl_name WHERE enum_col=0;
  ```

• The index of the NULL value is NULL.

• The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.
The ENUM Type

For example, a column specified as `ENUM('Mercury', 'Venus', 'Earth')` can have any of the values shown here. The index of each value is also shown.

<table>
<thead>
<tr>
<th>Value</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>''</td>
<td>0</td>
</tr>
<tr>
<td>'Mercury'</td>
<td>1</td>
</tr>
<tr>
<td>'Venus'</td>
<td>2</td>
</tr>
<tr>
<td>'Earth'</td>
<td>3</td>
</tr>
</tbody>
</table>

An `ENUM` column can have a maximum of 65,535 distinct elements.

If you retrieve an `ENUM` value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an `ENUM` column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `ENUM` values, the index number is used in the calculation.

Handling of Enumeration Literals

Trailing spaces are automatically deleted from `ENUM` member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an `ENUM` column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does not work with `LOAD DATA`, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).
To determine all possible values for an **ENUM** column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the **ENUM** definition in the **Type** column of the output.

In the C API, **ENUM** values are returned as strings. For information about using result set metadata to distinguish them from other strings, see Section 28.7.5, "C API Data Structures".

**Empty or NULL Enumeration Values**

An enumeration value can also be the empty string (`' '`) or **NULL** under certain circumstances:

- If you insert an invalid value into an **ENUM** (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a "normal" empty string by the fact that this string has the numeric value 0. See Index Values for Enumeration Literals for details about the numeric indexes for the enumeration values.

  If strict SQL mode is enabled, attempts to insert invalid **ENUM** values result in an error.

- If an **ENUM** column is declared to permit **NULL**, the **NULL** value is a valid value for the column, and the default value is **NULL**. If an **ENUM** column is declared **NOT NULL**, its default value is the first element of the list of permitted values.

**Enumeration Sorting**

**ENUM** values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, `'b'` sorts before `'a'` for `ENUM( 'b' , 'a' )`. The empty string sorts before nonempty strings, and **NULL** values sort before all other enumeration values.

To prevent unexpected results when using the **ORDER BY** clause on an **ENUM** column, use one of these techniques:

- Specify the **ENUM** list in alphabetic order.

- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST( col AS CHAR )` or `ORDER BY CONCAT( col )`.

**Enumeration Limitations**

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does **not** work because the **CONCAT** function cannot be used to construct an enumeration value:

```sql
CREATE TABLE sizes (
    size ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do **not** work:

```sql
SET @mysize = 'medium';
CREATE TABLE sizes (
    size ENUM('small', @mysize, 'large')
);
```

We strongly recommend that you do **not** use numbers as enumeration values, because it does not save on storage over the appropriate **TINYINT** or **SMALLINT** type, and it is easy to mix up the strings and the
underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See `Handling of Enumeration Literals` to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

11.4.5 The SET Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
'',
'one'
'two'
'one,two'
```

A `SET` column can have a maximum of 64 distinct members.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from `SET` member values in the table definition when a table is created.

When retrieved, values stored in a `SET` column are displayed using the lettercase that was used in the column definition. Note that `SET` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores `SET` values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a `SET` value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a `SET` column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a `SET` column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as `SET('a','b','c','d')`, the members have the following decimal and binary values.

<table>
<thead>
<tr>
<th><code>SET</code> Member</th>
<th>Decimal Value</th>
<th>Binary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
<td>0001</td>
</tr>
<tr>
<td>'b'</td>
<td>2</td>
<td>0010</td>
</tr>
<tr>
<td>'c'</td>
<td>4</td>
<td>0100</td>
</tr>
<tr>
<td>'d'</td>
<td>8</td>
<td>1000</td>
</tr>
</tbody>
</table>

If you assign a value of `9` to this column, that is `1001` in binary, so the first and fourth `SET` value members `'a'` and `'d'` are selected and the resulting value is `'a,d'`.

For a value containing more than one `SET` element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value.
The SET Type

When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as `SET('a', 'b', 'c', 'd')`:

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values `'a,d'`, `'d,a'`, `'a,d,d'`, `'a,d,a'`, and `'d,a,d'`:

```
mysql> INSERT INTO myset (col) VALUES
> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5  Duplicates: 0  Warnings: 0
```

Then all these values appear as `'a,d'` when retrieved:

```
mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
5 rows in set (0.04 sec)
```

If you set a `SET` column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)
```

```
mysql> SHOW WARNINGS;
+---------+------+------------------------------------------+
| Level   | Code | Message                                  |
+---------+------+------------------------------------------+
| Warning | 1265 | Data truncated for column 'col' at row 1  |
+---------+------+------------------------------------------+
1 row in set (0.04 sec)
```

```
mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid `SET` values result in an error.

`SET` values are sorted numerically. `NULL` values sort before non-`NULL` `SET` values.

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` values, the cast operation causes the numeric value to be used.

Normally, you search for `SET` values using the `FIND_IN_SET()` function or the `LIKE` operator:
The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to `'val1,val2'` returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a `SET` column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the `SET` definition in the `Type` column of the output.

In the C API, `SET` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see Section 28.7.5, “C API Data Structures”.

### 11.5 Spatial Data Types

The [Open Geospatial Consortium](http://www.opengeospatial.org) (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the [OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option](http://www.opengeospatial.org/standards/sfs), a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at [http://www.opengeospatial.org/standards/sfs](http://www.opengeospatial.org/standards/sfs).

Following the OGC specification, MySQL implements spatial extensions as a subset of the [SQL with Geometry Types](http://www.opengeospatial.org/standards/sfs) environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. For indexing spatial columns, `MyISAM` and `InnoDB` support both `SPATIAL` and non-`SPATIAL` indexes. The other storage engines support non-`SPATIAL` indexes, as described in Section 13.1.15, “CREATE INDEX Syntax”.

A [geographic feature](http://www.opengeospatial.org/standards/sfs) is anything in the world that has a location. A feature can be:
• An entity. For example, a mountain, a pond, a city.
• A space. For example, town district, the tropics.
• A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

**Geometry** is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used is **geometry**, defined as a point or an aggregate of points representing anything in the world that has a location.

The following material covers these topics:

• The spatial data types implemented in MySQL model
• The basis of the spatial extensions in the OpenGIS geometry model
• Data formats for representing spatial data
• How to use spatial data in MySQL
• Use of indexing for spatial data
• MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see Section 12.16, "Spatial Analysis Functions”.

### Additional Resources

These standards are important for the MySQL implementation of spatial operations:

• SQL/MM Part 3: Spatial.

• The grammar for spatial reference system (SRS) definitions is based on the grammar defined in *OpenGIS Implementation Specification: Coordinate Transformation Services*, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at [http://www.opengeospatial.org/standards/ct](http://www.opengeospatial.org/standards/ct). For differences from that specification in SRS definitions as implemented in MySQL, see Section 13.1.19, “CREATE SPATIAL REFERENCE SYSTEM Syntax”.

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: [https://forums.mysql.com/list.php?23](https://forums.mysql.com/list.php?23).

### 11.5.1 Spatial Data Types
MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in Section 11.5.2, “The OpenGIS Geometry Model”.

Some spatial data types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINESTRING`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINESTRING`, and `POLYGON`) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

- `MULTIPOINT`
- `MULTILINESTRING`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINESTRING`, and `MULTIPOLYGON`) restrict collection members to those having a particular geometry type.

Example: To create a table named `geom` that has a column named `g` that can store values of any geometry type, use this statement:

```sql
CREATE TABLE geom (g GEOMETRY);
```

Columns with a spatial data type can have an `SRID` attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For example:

```sql
CREATE TABLE geom (  
  p POINT SRID 0,  
  g GEOMETRY NOT NULL SRID 4326  
);
```

`SPATIAL` indexes can be created on spatial columns if they are `NOT NULL` and have a specific SRID, so if you plan to index the column, declare it with the `NOT NULL` and `SRID` attributes:

```sql
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
```

`InnoDB` tables permit `SRID` values for Cartesian and geographic SRSs. `MyISAM` tables permit `SRID` values for Cartesian SRSs.

The `SRID` attribute makes a spatial column SRID-restricted, which has these implications:

- The column can contain only values with the given SRID. Attempts to insert values with a different SRID produce an error.
- The optimizer can use `SPATIAL` indexes on the column. See Section 8.3.3, “SPATIAL Index Optimization”.

InnoDB tables permit `SRID` values for Cartesian and geographic SRSs. MyISAM tables permit `SRID` values for Cartesian SRSs.

The `SRID` attribute makes a spatial column SRID-restricted, which has these implications:

- The column can contain only values with the given SRID. Attempts to insert values with a different SRID produce an error.
- The optimizer can use `SPATIAL` indexes on the column. See Section 8.3.3, “SPATIAL Index Optimization”.

MyISAM tables permit `SRID` values for Cartesian and geographic SRSs.
Spatial columns with no `SRID` attribute are not SRID-restricted and accept values with any SRID. However, the optimizer cannot use `SPATIAL` indexes on them until the column definition is modified to include an `SRID` attribute, which may require that the column contents first be modified so that all values have the same SRID.

For other examples showing how to use spatial data types in MySQL, see Section 11.5.6, "Creating Spatial Columns". For information about spatial reference systems, see Section 11.5.5, “Spatial Reference System Support”.

11.5.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC’s SQL with Geometry Types environment is based on the OpenGIS Geometry Model. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

11.5.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- **Geometry** (noninstantiable)
  - **Point** (instantiable)
  - **Curve** (noninstantiable)
    - **LineString** (instantiable)
      - **Line**
      - **LinearRing**
  - **Surface** (noninstantiable)
    - **Polygon** (instantiable)
  - **GeometryCollection** (instantiable)
    - **MultiPoint** (instantiable)
    - **MultiCurve** (noninstantiable)
      - **MultiLineString** (instantiable)
    - **MultiSurface** (noninstantiable)
    - **MultiPolygon** (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

**Geometry** is the base class. It is an abstract class. The instantiable subclasses of **Geometry** are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate...
The base **Geometry** class has subclasses for **Point**, **Curve**, **Surface**, and **GeometryCollection**:

- **Point** represents zero-dimensional objects.
- **Curve** represents one-dimensional objects, and has subclass **LineString**, with sub-subclasses **Line** and **LinearRing**.
- **Surface** is designed for two-dimensional objects and has subclass **Polygon**.
- **GeometryCollection** has specialized zero-, one-, and two-dimensional collection classes named **MultiPoint**, **MultiLineString**, and **MultiPolygon** for modeling geometries corresponding to collections of **Points**, **LineStrings**, and **Polygons**, respectively. **MultiCurve** and **MultiSurface** are introduced as abstract superclasses that generalize the collection interfaces to handle **Curves** and **Surfaces**.

**Geometry**, **Curve**, **Surface**, **MultiCurve**, and **MultiSurface** are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

**Point**, **LineString**, **Polygon**, **GeometryCollection**, **MultiPoint**, **MultiLineString**, and **MultiPolygon** are instantiable classes.

### 11.5.2.2 Geometry Class

**Geometry** is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the **Geometry** subclasses. Particular subclasses have their own specific properties, described later.

#### Geometry Properties

A geometry value has the following properties:

- **Its type.** Each geometry belongs to one of the instantiable classes in the hierarchy.
- **Its SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

  In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

  SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

  For computations on multiple geometry values, all values must have the same SRID or an error occurs.

- **Its coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

  Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the planar coordinate system and the distance on the geodetic system (coordinates on the Earth's surface) are different things.

- **Its interior, boundary, and exterior.**
Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its MBR (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

  \[
  \{(MINX \ MINY, MAXX \ MINY, MAXX \ MAXY, MINX \ MAXY, MINX \ MINY)\}
  \]

- Whether the value is simple or nonsimple. Geometry values of types (LineString, MultiPoint, MultiLineString) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.

- Whether the value is closed or not closed. Geometry values of types (LineString, MultiString) are either closed or not closed. Each type determines its own assertions for being closed or not closed.

- Whether the value is empty or nonempty. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a NULL value). An empty geometry is defined to be always simple and has an area of 0.

- Its dimension. A geometry can have a dimension of −1, 0, 1, or 2:

  - −1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with nonzero length and zero area.
  - 2 for a geometry with nonzero area.

  Point objects have a dimension of zero. LineString objects have a dimension of 1. Polygon objects have a dimension of 2. The dimensions of MultiPoint, MultiLineString, and MultiPolygon objects are the same as the dimensions of the elements they consist of.

### 11.5.2.3 Point Class

A Point is a geometry that represents a single location in coordinate space.

**Point Examples**

- Imagine a large-scale map of the world with many cities. A Point object could represent each city.
- On a city map, a Point object could represent a bus stop.

**Point Properties**

- X-coordinate value.
- Y-coordinate value.
- Point is defined as a zero-dimensional geometry.
- The boundary of a Point is the empty set.

### 11.5.2.4 Curve Class

A Curve is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of Curve define the type of interpolation between points. Curve is a noninstantiable class.
**Curve** Properties

- A **Curve** has the coordinates of its points.
- A **Curve** is defined as a one-dimensional geometry.
- A **Curve** is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A **Curve** is closed if its start point is equal to its endpoint.
- The boundary of a closed **Curve** is empty.
- The boundary of a nonclosed **Curve** consists of its two endpoints.
- A **Curve** that is simple and closed is a **LinearRing**.

### 11.5.2.5 LineString Class

A **LineString** is a **Curve** with linear interpolation between points.

**LineString** Examples

- On a world map, **LineString** objects could represent rivers.
- In a city map, **LineString** objects could represent streets.

**LineString** Properties

- A **LineString** has coordinates of segments, defined by each consecutive pair of points.
- A **LineString** is a **Line** if it consists of exactly two points.
- A **LineString** is a **LinearRing** if it is both closed and simple.

### 11.5.2.6 Surface Class

A **Surface** is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is **Polygon**.

**Surface** Properties

- A **Surface** is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple **Surface** as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple **Surface** is the set of closed curves corresponding to its exterior and interior boundaries.

### 11.5.2.7 Polygon Class

A **Polygon** is a planar **Surface** representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the **Polygon**.

**Polygon** Examples

- On a region map, **Polygon** objects could represent forests, districts, and so on.
**Polygon Assertions**

- The boundary of a **Polygon** consists of a set of **LinearRing** objects (that is, **LineString** objects that are both simple and closed) that make up its exterior and interior boundaries.

- A **Polygon** has no rings that cross. The rings in the boundary of a **Polygon** may intersect at a **Point**, but only as a tangent.

- A **Polygon** has no lines, spikes, or punctures.

- A **Polygon** has an interior that is a connected point set.

- A **Polygon** may have holes. The exterior of a **Polygon** with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a **Polygon** a simple geometry.

### 11.5.2.8 GeometryCollection Class

A **GeomCollection** is a geometry that is a collection of zero or more geometries of any class.

**GeomCollection** and **GeometryCollection** are synonymous, with **GeomCollection** the preferred type name.

All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of **GeomCollection** described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a **MultiPoint** may contain only **Point** elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

### 11.5.2.9 MultiPoint Class

A **MultiPoint** is a geometry collection composed of **Point** elements. The points are not connected or ordered in any way.

**MultiPoint** Examples

- On a world map, a **MultiPoint** could represent a chain of small islands.
- On a city map, a **MultiPoint** could represent the outlets for a ticket office.

**MultiPoint** Properties

- A **MultiPoint** is a zero-dimensional geometry.
- A **MultiPoint** is simple if no two of its **Point** values are equal (have identical coordinate values).
- The boundary of a **MultiPoint** is the empty set.

### 11.5.2.10 MultiCurve Class

A **MultiCurve** is a geometry collection composed of **Curve** elements. **MultiCurve** is a noninstantiable class.
**MultiCurve Properties**

- A **MultiCurve** is a one-dimensional geometry.

- A **MultiCurve** is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.

- A **MultiCurve** boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a **MultiCurve** if it is in the boundaries of an odd number of **Curve** elements.

- A **MultiCurve** is closed if all of its elements are closed.

- The boundary of a closed **MultiCurve** is always empty.

11.5.2.11 **MultiLineString Class**

A **MultiLineString** is a **MultiCurve** geometry collection composed of **LineString** elements.

**MultiLineString Examples**

- On a region map, a **MultiLineString** could represent a river system or a highway system.

11.5.2.12 **MultiSurface Class**

A **MultiSurface** is a geometry collection composed of surface elements. **MultiSurface** is a noninstantiable class. Its only instantiable subclass is **MultiPolygon**.

**MultiSurface Assertions**

- Surfaces within a **MultiSurface** have no interiors that intersect.

- Surfaces within a **MultiSurface** have boundaries that intersect at most at a finite number of points.

11.5.2.13 **MultiPolygon Class**

A **MultiPolygon** is a **MultiSurface** object composed of **Polygon** elements.

**MultiPolygon Examples**

- On a region map, a **MultiPolygon** could represent a system of lakes.

**MultiPolygon Assertions**

- A **MultiPolygon** has no two **Polygon** elements with interiors that intersect.

- A **MultiPolygon** has no two **Polygon** elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.

- A **MultiPolygon** may not have cut lines, spikes, or punctures. A **MultiPolygon** is a regular, closed point set.

- A **MultiPolygon** that has more than one **Polygon** has an interior that is not connected. The number of connected components of the interior of a **MultiPolygon** is equal to the number of **Polygon** values in the **MultiPolygon**.

**MultiPolygon Properties**
11.5.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see Section 12.16.6, “Geometry Format Conversion Functions”.

The following sections describe the spatial data formats MySQL uses:

- Well-Known Text (WKT) Format
- Well-Known Binary (WKB) Format
- Internal Geometry Storage Format

**Well-Known Text (WKT) Format**

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see Section 11.5, “Spatial Data Types”).

Examples of WKT representations of geometry objects:

- A Point:

  POINT(15 20)

  The point coordinates are specified with no separating comma. This differs from the syntax for the SQL `Point()` function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use `ST_X()` to extract the X-coordinate from a Point object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a Point with `ST_GeomFromText()`.

  ```sql
  mysql> SELECT ST_X(Point(15, 20));
  +---------------------+
  | ST_X(POINT(15, 20)) |
  | 15                  |
  +---------------------+
  ```
Supported Spatial Data Formats

Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by BLOB values containing geometric WKB information. This format is defined by the OpenGIS specification (see Section 11.5, “Spatial Data Types”). It is also defined in the ISO SQL/MM Part 3: Spatial standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to POINT(1 -1) consists of this sequence of 21 bytes, each represented by two hexadecimal digits:
The sequence consists of the components shown in the following table.

Table 11.2 WKB Components Example

<table>
<thead>
<tr>
<th>Component</th>
<th>Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte order</td>
<td>1 byte</td>
<td>01</td>
</tr>
<tr>
<td>WKB type</td>
<td>4 bytes</td>
<td>01000000</td>
</tr>
<tr>
<td>X coordinate</td>
<td>8 bytes</td>
<td>000000000000F03F</td>
</tr>
<tr>
<td>Y coordinate</td>
<td>8 bytes</td>
<td>000000000000F0BF</td>
</tr>
</tbody>
</table>

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection.

- A Point value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

**Internal Geometry Storage Format**

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see [Well-Known Binary (WKB) Format](#).

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-ending values.

- MySQL supports geometry types of Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection. Other geometry types are not supported.

- Only GeometryCollection can be empty. Such a value is stored with 0 elements.

- Polygon rings can be specified both clockwise and counterclockwise. MySQL flips the rings automatically when reading data.

Cartesian coordinates are stored in the length unit of the spatial reference system, with X values in the X coordinates and Y values in the Y coordinates. Axis directions are those specified by the spatial reference system.

Geographic coordinates are stored in the angle unit of the spatial reference system, with longitudes in the X coordinates and latitudes in the Y coordinates. Axis directions and the meridian are those specified by the spatial reference system.

The `LENGTH()` function returns the space in bytes required for value storage. Example:
The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)
- 4 bytes for integer type information (1 = Point)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (-1)

### 11.5.4 Geometry Well-Formedness and Validity

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)
- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except GeometryCollection)

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
- Polygon interior rings are inside the exterior ring
- Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also
11.5.5 Spatial Reference System Support

A spatial reference system (SRS) for spatial data is a coordinate-based system for geographic locations. There are different types of spatial reference systems:

• A projected SRS is a projection of a globe onto a flat surface; that is, a flat map. For example, a light bulb inside a globe that shines on a paper cylinder surrounding the globe projects a map onto the paper. The result is georeferenced: Each point maps to a place on the globe. The coordinate system on that plane is Cartesian using a length unit (meters, feet, and so forth), rather than degrees of longitude and latitude.

The globes in this case are ellipsoids; that is, flattened spheres. Earth is a bit shorter in its North-South axis than its East-West axis, so a slightly flattened sphere is more correct, but perfect spheres permit faster calculations.

• A geographic SRS is a nonprojected SRS representing longitude-latitude (or latitude-longitude) coordinates on an ellipsoid, in any angular unit.

• The SRS denoted in MySQL by SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. Unlike projected SRSs, it is not georeferenced and it does not necessarily represent Earth. It is an abstract plane that can be used for anything. SRID 0 is the default SRID for spatial data in MySQL.

MySQL maintains information about available spatial reference systems for spatial data in the data dictionary mysql.st_spatial_reference_systems table, which can store entries for projected and geographic SRSs. This data dictionary table is invisible, but SRS entry contents are available through the INFORMATION_SCHEMA. ST_SPATIAL_REFERENCE_SYSTEMS table, implemented as a view on mysql.st_spatial_reference_systems (see Section 25.28, “The INFORMATION_SCHEMA ST_SPATIAL_REFERENCE_SYSTEMS Table”).

The following example shows what an SRS entry looks like:

```sql
mysql> SELECT *
FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS
WHERE SRS_ID = 4326
```

```
*************************** 1. row ***************************
SRS_NAME: WGS 84
SRS_ID: 4326
ORGANIZATION: EPSG
ORGANIZATION_COORDSYS_ID: 4326
DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984", SPHEROID["WGS 84",6378137,298.257223563, AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]], PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]], UNIT["degree",0.017453292519943278, AUTHORITY["EPSG","9122"]], AXIS["Lat",NORTH],AXIS["Long",EAST], AUTHORITY["EPSG","4326"]]
DESCRIPTION: This entry describes the SRS used for GPS systems. It has a name (SRS_NAME) of WGS 84 and an ID (SRS_ID) of 4326, which is the ID used by the European Petroleum Survey Group (EPSG).

SRS definitions in the DEFINITION column are WKT values, represented as specified in the Open Geospatial Consortium document OGC 12-063r5.
```
SRS_ID values represent the same kind of values passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

SRS definition parsing occurs on demand when definitions are needed by GIS functions. Parsed definitions are cached in the data dictionary cache so that parsing overhead is not incurred for every statement that needs SRS information.

To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

• **CREATE SPATIAL REFERENCE SYSTEM**: See Section 13.1.19, “CREATE SPATIAL REFERENCE SYSTEM Syntax”. The description for this statement includes additional information about SRS components.

• **DROP SPATIAL REFERENCE SYSTEM**: See Section 13.1.31, “DROP SPATIAL REFERENCE SYSTEM Syntax”.

### 11.5.6 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with CREATE TABLE or ALTER TABLE. Spatial columns are supported for MyISAM, InnoDB, NDB, and ARCHIVE tables. See also the notes about spatial indexes under Section 11.5.10, “Creating Spatial Indexes”.

Columns with a spatial data type can have an SRID attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For implications of an SRID-restricted column, see Section 11.5.1, “Spatial Data Types”.

• Use the CREATE TABLE statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

• Use the ALTER TABLE statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

### 11.5.7 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

• Perform the conversion directly in the INSERT statement:

```
INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

• Perform the conversion prior to the INSERT:
The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2,3 4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use \texttt{ST\_GeomFromText()} to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2,3 4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a \texttt{POINT(1 1)} value with hex literal syntax:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(X'01010000000000000000F03F0000000000000F03F'));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of \texttt{BLOB} type:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using \texttt{mysql\_real\_escape\_string\_quote()} and include the result in a query string that is sent to the server. See Section 28.7.7.56, "mysql\_real\_escape\_string\_quote()".

### 11.5.8 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:

  Fetching geometry values using internal format can be useful in table-to-table transfers:
11.5.9 Optimizing Spatial Analysis

For **MyISAM** and **InnoDB** tables, search operations in columns containing spatial data can be optimized using **SPATIAL** indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for **SPATIAL** indexes on spatial columns. A **SPATIAL** index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-**SPATIAL** index, you must declare a prefix for any spatial column except for **POINT** columns.

**MyISAM** and **InnoDB** support both **SPATIAL** and non-**SPATIAL** indexes. Other storage engines support non-**SPATIAL** indexes, as described in Section 13.1.15, “CREATE INDEX Syntax”.

11.5.10 Creating Spatial Indexes

For **InnoDB** and **MyISAM** tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the **SPATIAL** keyword. Columns in spatial indexes must be declared **NOT NULL**. The following examples demonstrate how to create spatial indexes:

- With **CREATE TABLE**:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326, SPATIAL INDEX(g));
```

- With **ALTER TABLE**:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With **CREATE INDEX**:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
```
CREATE SPATIAL INDEX g ON geom (g);

**SPATIAL INDEX** creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

The optimizer can use spatial indexes defined on columns that are SRID-restricted. For more information, see Section 11.5.1, “Spatial Data Types”, and Section 8.3.3, “SPATIAL Index Optimization”.

For more information on indexing spatial columns, see Section 13.1.15, “CREATE INDEX Syntax”.

To drop spatial indexes, use **ALTER TABLE** or **DROP INDEX**:

- With **ALTER TABLE**:

  ```
  ALTER TABLE geom DROP INDEX g;
  ```

- With **DROP INDEX**:

  ```
  DROP INDEX g ON geom;
  ```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-------+----------+------+-----+---------+----------------+
| Field | Type     | Null | Key | Default | Extra          |
|-------+----------+------+-----+---------+----------------|
| fid   | int(11)  |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                |
+-------+----------+------+-----+---------+----------------+
2 rows in set (0.00 sec)
```

```
mysql> SELECT COUNT(*) FROM geom;
+----------+
<table>
<thead>
<tr>
<th>count(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>32376</td>
</tr>
</tbody>
</table>
+----------+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376  Duplicates: 0  Warnings: 0
```

### 11.5.11 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the **WHERE** clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly = 
   -> 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';
```
Using Spatial Indexes

```sql
mysql> SELECT fid, ST_AsText(g) FROM geom WHERE MBRContains(ST_GeomFromText('Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))'), g);

+-----+---------------------------------------------------------------+
<table>

<td>LINESTRING(30269.8 15084, 30269.4 15093.4, 30258.6 15093, 30 ...</td>
</tr>
<tr>
<td>157</td>
<td>LINESTRING(30128.2 15011, 30113.2 15010.2, 30113.6 15000.4, 30 ...</td>
</tr>
</tbody>
</table>
+-----+---------------------------------------------------------------+
20 rows in set (0.00 sec)
```

Use `EXPLAIN` to check the way this query is executed:

```sql
mysql> SET @poly = 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';

mysql> EXPLAIN SELECT fid, ST_AsText(g) FROM geom WHERE MBRContains(ST_GeomFromText('Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))'), g)
```

```text
| id: 1
| select_type: SIMPLE
| table: geom
| type: range
| possible_keys: g
| key: g
| key_len: 32
| ref: NULL
| rows: 50
| Extra: Using where
|```

1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```sql
mysql> SET @poly = 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';

mysql> EXPLAIN SELECT fid, ST_AsText(g) FROM geom WHERE MBRContains(ST_GeomFromText('Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))'), g)
```

```text
| id: 1
```
Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```sql
mysql> SET @poly = 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';

mysql> SELECT fid, ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE MBRContains(ST_GeomFromText (@poly), g);
```

11.6 The JSON Data Type

- Creating JSON Values
- Normalization, Merging, and Autowrapping of JSON Values
- Searching and Modifying JSON Values
- JSON Path Syntax
- Comparison and Ordering of JSON Values
- Converting between JSON and non-JSON values
- Aggregation of JSON Values
MySQL supports a native JSON data type defined by RFC 7159 that enables efficient access to data in JSON (JavaScript Object Notation) documents. The JSON data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in JSON columns. Invalid documents produce an error.

- Optimized storage format. JSON documents stored in JSON columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

MySQL 8.0 also supports the JSON Merge Patch format defined in RFC 7396, using the JSON_MERGE_PATCH() function. See the description of this function, as well as Normalization, Merging, and Autowrapping of JSON Values, for examples and further information.

**Note**

This discussion uses JSON in monotype to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a JSON document is roughly the same as for LONGBLOB or LONGTEXT; see Section 11.8, “Data Type Storage Requirements”, for more information. It is important to keep in mind that the size of any JSON document stored in a JSON column is limited to the value of the max_allowed_packet system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.) You can obtain the amount of space required to store a JSON document using the JSON_STORAGE_SIZE() function; note that for a JSON column, the storage size—and thus the value returned by this function—is that used by the column prior to any partial updates that may have been performed on it (see the discussion of the JSON partial update optimization later in this section).

Prior to MySQL 8.0.13, a JSON column cannot have a non-NULL default value.

Along with the JSON data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see Section 12.17, “JSON Functions”.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.16.11, “Spatial GeoJSON Functions”.

JSON columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

MySQL NDB Cluster 8.0 supports JSON columns and MySQL JSON functions, including creation of an index on a column generated from a JSON column as a workaround for being unable to index a JSON column. A maximum of 3 JSON columns per NDB table is supported.

**Partial Updates of JSON Values**

In MySQL 8.0, the optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update that meets the following conditions:

- The column being updated was declared as JSON.
Creating JSON Values

- The UPDATE statement uses any of the three functions JSON_SET(), JSON_REPLACE(), or JSON_REMOVE() to update the column. A direct assignment of the column value (for example, UPDATE mytable SET jcol = '{"a": 10, "b": 25}') cannot be performed as a partial update.

Updates of multiple JSON columns in a single UPDATE statement can be optimized in this fashion; MySQL can perform partial updates of only those columns whose values are updated using the three functions just listed.

- The input column and the target column must be the same column; a statement such as UPDATE mytable SET jcol1 = JSON_SET(jcol2, '$.a', 100) cannot be performed as a partial update.

The update can use nested calls to any of the functions listed in the previous item, in any combination, as long as the input and target columns are the same.

- All changes replace existing array or object values with new ones, and do not add any new elements to the parent object or array.

- The value being replaced must be at least as large as the replacement value. In other words, the new value cannot be any larger than the old one.

A possible exception to this requirement occurs when a previous partial update has left sufficient space for the larger value. You can use the function JSON_STORAGE_FREE() to see how much space has been freed by any partial updates of a JSON column.

Such partial updates can be written to the binary log using a compact format that saves space; this can be enabled by setting the binlog_row_value_options system variable to PARTIAL_JSON. See the description of this variable for more information.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within [ and ] characters:

`["abc", 10, null, true, false]`

A JSON object contains a set of key-value pairs separated by commas and enclosed within { and } characters:

`{"k1": "value", "k2": 10}`

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

Nesting is permitted within JSON array elements and JSON object key values:

`[99, {"id": "HK500", "cost": 75.99}, ["hot", "cold"]]
{"k1": "value", "k2": [10, 20]}`

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see Section 12.17.2, “Functions That Create JSON Values”) as well as by casting values of other types to the
Creating JSON Values

JSON type using CAST(value AS JSON) (see Converting between JSON and non-JSON values). The
next several paragraphs describe how MySQL handles JSON values provided as input.
In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires
a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value
into a column that has the JSON data type and passing an argument to a function that expects a JSON
value (usually shown as json_doc or json_val in the documentation for MySQL JSON functions), as the
following examples demonstrate:
• Attempting to insert a value into a JSON column succeeds if the value is a valid JSON value, but fails if it
is not:
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)
mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
Query OK, 1 row affected (0.01 sec)
mysql> INSERT INTO t1 VALUES('[1, 2,');
ERROR 3140 (22032) at line 2: Invalid JSON text:
"Invalid value." at position 6 in value (or column) '[1, 2,'.

Positions for “at position N” in such error messages are 0-based, but should be considered rough
indications of where the problem in a value actually occurs.
• The JSON_TYPE() function expects a JSON argument and attempts to parse it into a JSON value. It
returns the value's JSON type if it is valid and produces an error otherwise:
mysql> SELECT JSON_TYPE('["a", "b", 1]');
+----------------------------+
| JSON_TYPE('["a", "b", 1]') |
+----------------------------+
| ARRAY
|
+----------------------------+
mysql> SELECT JSON_TYPE('"hello"');
+----------------------+
| JSON_TYPE('"hello"') |
+----------------------+
| STRING
|
+----------------------+
mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

MySQL handles strings used in JSON context using the utf8mb4 character set and utf8mb4_bin
collation. Strings in other character sets are converted to utf8mb4 as necessary. (For strings in the ascii
or utf8 character sets, no conversion is needed because ascii and utf8 are subsets of utf8mb4.)
As an alternative to writing JSON values using literal strings, functions exist for composing JSON values
from component elements. JSON_ARRAY() takes a (possibly empty) list of values and returns a JSON
array containing those values:
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+----------------------------------------+
| JSON_ARRAY('a', 1, NOW())
|
+----------------------------------------+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+----------------------------------------+

1776


**JSON_OBJECT()** takes a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+---------------------------------------+  
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
+---------------------------------------+  
| {"key1": 1, "key2": "abc"}          |
+---------------------------------------+  
```

**JSON_MERGE_PRESERVE()** takes two or more JSON documents and returns the combined result:

```
mysql> SELECT JSON_MERGE_PRESERVE('a', 1, '{"key": "value"}');
+-----------------------------------------------+  
| JSON_MERGE_PRESERVE('a', 1, '{"key": "value"}') |
+-----------------------------------------------+  
| ["a", 1, {"key": "value"}]                  |
+-----------------------------------------------+  
```

For information about the merging rules, see [Normalization, Merging, and Autowrapping of JSON Values](#).

(MySQL 8.0.3 and later also support **JSON_MERGE_PATCH()**, which has somewhat different behavior. See [JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE()](#), for information about the differences between these two functions.)

JSON values can be assigned to user-defined variables:

```
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+------------------+  
| @j               |
+------------------+  
| {"key": "value"}|
+------------------+  
```

However, user-defined variables cannot be of **JSON** data type, so although @j in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it does not have the **JSON** data type. Instead, the result from **JSON_OBJECT()** is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of **utf8mb4** and a collation of **utf8mb4_bin**:

```
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-------------+---------------+
| CHARSET(@j) | COLLATION(@j) |
+-------------+---------------+
| utf8mb4     | utf8mb4_bin   |
+-------------+---------------+
```

Because **utf8mb4_bin** is a binary collation, comparison of JSON values is case-sensitive.
Creating JSON Values

Case sensitivity also applies to the JSON null, true, and false literals, which always must be written in lowercase:

```sql
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+-------------------+-------------------+-------------------+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+-------------------+-------------------+-------------------+
|                  1 |                  0 |                  0 |
+-------------------+-------------------+-------------------+
```

Case sensitivity of the JSON literals differs from that of the SQL NULL, TRUE, and FALSE literals, which can be written in any lettercase:

```sql
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+--------------+--------------+--------------+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+--------------+--------------+--------------+
|            1 |            1 |            1 |
+--------------+--------------+--------------+
```

Sometimes it may be necessary or desirable to insert quote characters (" or ") into a JSON document. Assume for this example that you want to insert some JSON objects containing strings representing sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table created using the SQL statement shown here:

```sql
mysql> CREATE TABLE facts (sentence JSON);
```

Among these keyword-sentence pairs is this one:

mascot: The MySQL mascot is a dolphin named "Sakila".

One way to insert this as a JSON object into the facts table is to use the MySQL JSON_OBJECT() function. In this case, you must escape each quote character using a backslash, as shown here:

```sql
mysql> INSERT INTO facts VALUES
    
    (JSON_OBJECT("mascot", "Our mascot is a dolphin named \"Sakila\".");
```

This does not work in the same way if you insert the value as a JSON object literal, in which case, you must use the double backslash escape sequence, like this:

```sql
mysql> INSERT INTO facts VALUES
```
Normalization, Merging, and Autowrapping of JSON Values

>

('{"mascot": "Our mascot is a dolphin named \\"Sakila\\"."}');

Using the double backslash keeps MySQL from performing escape sequence processing, and instead
causes it to pass the string literal to the storage engine for processing. After inserting the JSON object in
either of the ways just shown, you can see that the backslashes are present in the JSON column value by
doing a simple SELECT, like this:
mysql> SELECT sentence FROM facts;
+---------------------------------------------------------+
| sentence
|
+---------------------------------------------------------+
| {"mascot": "Our mascot is a dolphin named \"Sakila\"."} |
+---------------------------------------------------------+

To look up this particular sentence employing mascot as the key, you can use the column-path operator >, as shown here:
mysql> SELECT col->"$.mascot" FROM qtest;
+---------------------------------------------+
| col->"$.mascot"
|
+---------------------------------------------+
| "Our mascot is a dolphin named \"Sakila\"." |
+---------------------------------------------+
1 row in set (0.00 sec)

This leaves the backslashes intact, along with the surrounding quote marks. To display the desired value
using mascot as the key, but without including the surrounding quote marks or any escapes, use the inline
path operator ->>, like this:
mysql> SELECT sentence->>"$.mascot" FROM facts;
+-----------------------------------------+
| sentence->>"$.mascot"
|
+-----------------------------------------+
| Our mascot is a dolphin named "Sakila". |
+-----------------------------------------+

Note
The previous example does not work as shown if the NO_BACKSLASH_ESCAPES
server SQL mode is enabled. If this mode is set, a single backslash instead
of double backslashes can be used to insert the JSON object literal, and the
backslashes are preserved. If you use the JSON_OBJECT() function when
performing the insert and this mode is set, you must alternate single and double
quotes, like this:
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));

See the description of the JSON_UNQUOTE() function for more information about
the effects of this mode on escaped characters in JSON values.

Normalization, Merging, and Autowrapping of JSON Values
When a string is parsed and found to be a valid JSON document, it is also normalized. This means
that members with keys that duplicate a key found later in the document, reading from left to right, are
discarded. The object value produced by the following JSON_OBJECT() call includes only the second
key1 element because that key name occurs earlier in the value, as shown here:

1779


Normalization is also performed when values are inserted into JSON columns, as shown here:

```sql
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES
    > ("{"x": 17, "x": "red"}"),
    > ("{"x": 17, "x": "red", "x": [3, 5, 7]}");

mysql> SELECT c1 FROM t1;
```

```
+------------------+
| c1               |
| +------------------+
| {"x": "red"}     |
| {"x": [3, 5, 7]} |
+------------------+
```

This “last duplicate key wins” behavior is suggested by RFC 7159 and is implemented by most JavaScript parsers. (Bug #86866, Bug #26369555)

In versions of MySQL prior to 8.0.3, members with keys that duplicated a key found earlier in the document were discarded. The object value produced by the following `JSON_OBJECT()` call does not include the second `key1` element because that key name occurs earlier in the value:

```sql
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
```

```
+------------------------------------------------------+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
| +------------------------------------------------------+
| {"key1": "def", "key2": "abc"}                      |
+------------------------------------------------------+
```

Prior to MySQL 8.0.3, this “first duplicate key wins” normalization was also performed when inserting values into JSON columns.

MySQL also discards extra whitespace between keys, values, or elements in the original JSON document. To make lookups more efficient, it also sorts the keys of a JSON object. You should be aware that the result of this ordering is subject to change and not guaranteed to be consistent across releases.

MySQL functions that produce JSON values (see Section 12.17.2, “Functions That Create JSON Values”) always return normalized values.
Normalization, Merging, and Autowrapping of JSON Values

Merging JSON Values
Two merging algorithms are supported in MySQL 8.0.3 (and later), implemented by the functions
JSON_MERGE_PRESERVE() and JSON_MERGE_PATCH(). These differ in how they handle duplicate keys:
JSON_MERGE_PRESERVE() retains values for duplicate keys, while JSON_MERGE_PATCH() discards all
but the last value. The next few paragraphs explain how each of these two functions handles the merging
of different combinations of JSON documents (that is, of objects and arrays).
Note
JSON_MERGE_PRESERVE() is the same as the JSON_MERGE() function found
in previous versions of MySQL (renamed in MySQL 8.0.3). JSON_MERGE() is
still supported as an alias for JSON_MERGE_PRESERVE() in MySQL 8.0, but is
deprecated and subject to removal in a future release.
Merging arrays.
In contexts that combine multiple arrays, the arrays are merged into a single array.
JSON_MERGE_PRESERVE() does this by concatenating arrays named later to the end of the first array.
JSON_MERGE_PATCH() considers each argument as an array consisting of a single element (thus having
0 as its index) and then applies “last duplicate key wins” logic to select only the last argument. You can
compare the results shown by this query:
mysql> SELECT
->
JSON_MERGE_PRESERVE('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Preserve,
->
JSON_MERGE_PATCH('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Patch\G
*************************** 1. row ***************************
Preserve: [1, 2, "a", "b", "c", true, false]
Patch: [true, false]

Multiple objects when merged produce a single object. JSON_MERGE_PRESERVE() handles multiple
objects having the same key by combining all unique values for that key in an array; this array is then used
as the value for that key in the result. JSON_MERGE_PATCH() discards values for which duplicate keys are
found, working from left to right, so that the result contains only the last value for that key. The following
query illustrates the difference in the results for the duplicate key a:
mysql> SELECT
->
JSON_MERGE_PRESERVE('{"a": 1, "b": 2}', '{"c": 3, "a": 4}', '{"c": 5, "d": 3}') AS Preserve,
->
JSON_MERGE_PATCH('{"a": 3, "b": 2}', '{"c": 3, "a": 4}', '{"c": 5, "d": 3}') AS Patch\G
*************************** 1. row ***************************
Preserve: {"a": [1, 4], "b": 2, "c": [3, 5], "d": 3}
Patch: {"a": 4, "b": 2, "c": 5, "d": 3}

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded
by [ and ] characters to convert it to an array. In the following statement, each argument is autowrapped
as an array ([1], [2]). These are then merged to produce a single result array; as in the previous two
cases, JSON_MERGE_PRESERVE() combines values having the same key while JSON_MERGE_PATCH()
discards values for all duplicate keys except the last, as shown here:
mysql> SELECT
->
JSON_MERGE_PRESERVE('1', '2') AS Preserve,
->
JSON_MERGE_PATCH('1', '2') AS Patch\G
*************************** 1. row ***************************
Preserve: [1, 2]
Patch: 2

Array and object values are merged by autowrapping the object as an array and merging the arrays
by combining values or by “last duplicate key wins” according to the choice of merging function
(JSON_MERGE_PRESERVE() or JSON_MERGE_PATCH(), respectively), as can be seen in this example:

1781


Searching and Modifying JSON Values

mysql> SELECT
->
JSON_MERGE_PRESERVE('[10, 20]', '{"a": "x", "b": "y"}') AS Preserve,
->
JSON_MERGE_PATCH('[10, 20]', '{"a": "x", "b": "y"}') AS Patch\G
*************************** 1. row ***************************
Preserve: [10, 20, {"a": "x", "b": "y"}]
Patch: {"a": "x", "b": "y"}

Searching and Modifying JSON Values
A JSON path expression selects a value within a JSON document.
Path expressions are useful with functions that extract parts of or modify a JSON document, to specify
where within that document to operate. For example, the following query extracts from a JSON document
the value of the member with the name key:
mysql> SELECT JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name');
+---------------------------------------------------------+
| JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name') |
+---------------------------------------------------------+
| "Aztalan"
|
+---------------------------------------------------------+

Path syntax uses a leading $ character to represent the JSON document under consideration, optionally
followed by selectors that indicate successively more specific parts of the document:
• A period followed by a key name names the member in an object with the given key. The key name
must be specified within double quotation marks if the name without quotes is not legal within path
expressions (for example, if it contains a space).
• [N] appended to a path that selects an array names the value at position N within the array. Array
positions are integers beginning with zero. If path does not select an array value, path[0] evaluates to
the same value as path:
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+------------------------------+
| JSON_SET('"x"', '$[0]', 'a') |
+------------------------------+
| "a"
|
+------------------------------+
1 row in set (0.00 sec)

• [M to N] specifies a subset or range of array values starting with the value at position M, and ending
with the value at position N.
last is supported as a synonym for the index of the rightmost array element. Relative addressing of
array elements is also supported. If path does not select an array value, path[last] evaluates to the
same value as path, as shown later in this section (see Rightmost array element).
• Paths can contain * or ** wildcards:
• .[*] evaluates to the values of all members in a JSON object.
• [*] evaluates to the values of all elements in a JSON array.
• prefix**suffix evaluates to all paths that begin with the named prefix and end with the named
suffix.
• A path that does not exist in the document (evaluates to nonexistent data) evaluates to NULL.

1782


Searching and Modifying JSON Values

Let $ refer to this JSON array with three elements:
[3, {"a": [5, 6], "b": 10}, [99, 100]]

Then:
• $[0] evaluates to 3.
• $[1] evaluates to {"a": [5, 6], "b": 10}.
• $[2] evaluates to [99, 100].
• $[3] evaluates to NULL (it refers to the fourth array element, which does not exist).
Because $[1] and $[2] evaluate to nonscalar values, they can be used as the basis for more-specific
path expressions that select nested values. Examples:
• $[1].a evaluates to [5, 6].
• $[1].b evaluates to 10.
• $[2][0] evaluates to 99.
As mentioned previously, path components that name keys must be quoted if the unquoted key name is
not legal in path expressions. Let $ refer to this value:
{"a fish": "shark", "a bird": "sparrow"}

The keys both contain a space and must be quoted:
• $."a fish" evaluates to shark.
• $."a bird" evaluates to sparrow.
Paths that use wildcards evaluate to an array that can contain multiple values:
mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*');
+---------------------------------------------------------+
| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*') |
+---------------------------------------------------------+
| [1, 2, [3, 4, 5]]
|
+---------------------------------------------------------+
mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]');
+------------------------------------------------------------+
| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]') |
+------------------------------------------------------------+
| [3, 4, 5]
|
+------------------------------------------------------------+

In the following example, the path $**.b evaluates to multiple paths ($.a.b and $.c.b) and produces an
array of the matching path values:
mysql> SELECT JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b');
+---------------------------------------------------------+
| JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b') |
+---------------------------------------------------------+

1783


Searching and Modifying JSON Values

Ranges from JSON arrays. You can use ranges with the `to` keyword to specify subsets of JSON arrays. For example, `$[1 to 3]` includes the second, third, and fourth elements of an array, as shown here:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]');
+----------------------------------------------+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]') |
+----------------------------------------------+
| [2, 3, 4]                                    |
+----------------------------------------------+
1 row in set (0.00 sec)
```

The syntax is $M$ to $N$, where $M$ and $N$ are, respectively, the first and last indexes of a range of elements from a JSON array. $N$ must be greater than $M$; $M$ must be greater than or equal to 0. Array elements are indexed beginning with 0.

You can use ranges in contexts where wildcards are supported.

Rightmost array element. The `last` keyword is supported as a synonym for the index of the last element in an array. Expressions of the form `last - N` can be used for relative addressing, and within range definitions, like this:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]');
+--------------------------------------------------------+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]') |
+--------------------------------------------------------+
| [2, 3, 4]                                              |
+--------------------------------------------------------+
1 row in set (0.01 sec)
```

If the path is evaluated against a value that is not an array, the result of the evaluation is the same as if the value had been wrapped in a single-element array:

```
mysql> SELECT JSON_REPLACE("Sakila", '$[last]', 10);
+-----------------------------------------+
| JSON_REPLACE("Sakila", '$[last]', 10) |
+-----------------------------------------+
| 10                                      |
+-----------------------------------------+
1 row in set (0.00 sec)
```

You can use `column->path` with a JSON column identifier and JSON path expression as a synonym for `JSON_EXTRACT(column, path)`. See Section 12.17.3, “Functions That Search JSON Values”, for more information. See also Indexing a Generated Column to Provide a JSON Column Index.

Some functions take an existing JSON document, modify it in some way, and return the resulting modified document. Path expressions indicate where in the document to make changes. For example, the `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions each take a JSON document, plus one or more path-value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexistent values within the document.

Consider this document:

```
mysql> SET @j = '"a", {"b": [true, false], [10, 20]}';
```
JSON Path Syntax

**JSON_SET()** replaces values for paths that exist and adds values for paths that do not exist:

```sql
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

In this case, the path `$[1].b[0]` selects an existing value (`true`), which is replaced with the value following the path argument (1). The path `$[2][2]` does not exist, so the corresponding value (2) is added to the value selected by `$[2]`.

**JSON_INSERT()** adds new values but does not replace existing values:

```sql
mysql> SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

**JSON_REPLACE()** replaces existing values and ignores new values:

```sql
mysql> SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

**JSON_REMOVE()** takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```sql
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]');
```

The paths have these effects:

- The first instance of `$[1].b[1]` matches `false` in the `b` element and removes it.
- The second instance of `$[1].b[1]` matches nothing: That element has already been removed, the path no longer exists, and has no effect.

**JSON Path Syntax**

Many of the JSON functions supported by MySQL and described elsewhere in this Manual (see Section 12.17, “JSON Functions”) require a path expression in order to identify a specific element in a
JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading $ character. Path legs are separated by period characters (.). Cells in arrays are represented by \([N]\), where \(N\) is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see http://www.ecma-international.org/ecma-262/5.1/#sec-7.6). Path expressions, like JSON text, should be encoded using the ascii, utf8, or utf8mb4 character set. Other character encodings are implicitly coerced to utf8mb4. The complete syntax is shown here:

\[
\text{pathExpression:} \\
\text{scope[({pathLeg})*]}
\]

\[
\text{pathLeg:} \\
\text{member | arrayLocation | doubleAsterisk}
\]

\[
\text{member:} \\
\text{period ( keyName | asterisk )}
\]

\[
\text{arrayLocation:} \\
\text{leftBracket ( nonNegativeInteger | asterisk ) rightBracket}
\]

\[
\text{keyName:} \\
\text{ESIdentifier | doubleQuotedString}
\]

\[
\text{doubleAsterisk:} \\
\text{'**'}
\]

\[
\text{period:} \\
\text{'.'}
\]

\[
\text{asterisk:} \\
\text{'*' }
\]

\[
\text{leftBracket:} \\
\text{['}
\]

\[
\text{rightBracket:} \\
\text{']}
\]

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as $\$. You can use '$$' as a synonym for the document in JSON path expressions.

**Note**

Some implementations support column references for scopes of JSON paths; currently, MySQL does not support these.

The wildcard * and ** tokens are used as follows:

- \(.*\) represents the values of all members in the object.
- \([*]\) represents the values of all cells in the array.
- \([prefix]**sufffix\) represents all paths beginning with prefix and ending with suffix. prefix is optional, while suffix is required; in other words, a path may not end in **.

In addition, a path may not contain the sequence ***.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as JSON_CONTAINS_PATH(), JSON_SET(), and JSON_REPLACE(). For examples which include the use of the * and ** wildcards, see the description of the JSON_SEARCH() function.
MySQL 8.0.2 and later also supports range notation for subsets of JSON arrays using the to keyword (such as $[2 to 10]$), as well as the last keyword as a synonym for the rightmost element of an array. See Searching and Modifying JSON Values, for more information and examples.

Comparison and Ordering of JSON Values

JSON values can be compared using the =, <, <=, >, >=, !=, and <=> operators.

The following comparison operators and functions are not yet supported with JSON values:

• BETWEEN
• IN()
• GREATEST()
• LEAST()

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the JSON_TYPE() function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOB</td>
</tr>
<tr>
<td>BIT</td>
</tr>
<tr>
<td>OPAQUE</td>
</tr>
<tr>
<td>DATETIME</td>
</tr>
<tr>
<td>TIME</td>
</tr>
<tr>
<td>DATE</td>
</tr>
<tr>
<td>BOOLEAN</td>
</tr>
<tr>
<td>ARRAY</td>
</tr>
<tr>
<td>OBJECT</td>
</tr>
<tr>
<td>STRING</td>
</tr>
<tr>
<td>INTEGER, DOUBLE</td>
</tr>
<tr>
<td>NULL</td>
</tr>
</tbody>
</table>

For JSON values of the same precedence, the comparison rules are type specific:

• BLOB

  The first $N$ bytes of the two values are compared, where $N$ is the number of bytes in the shorter value. If the first $N$ bytes of the two values are identical, the shorter value is ordered before the longer value.

• BIT

  Same rules as for BLOB.

• OPAQUE

  Same rules as for BLOB. OPAQUE values are values that are not classified as one of the other types.
Comparison and Ordering of JSON Values

- **DATETIME**
  A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL `DATETIME` and `TIMESTAMP` types, respectively, they are equal if they represent the same point in time.

- **TIME**
  The smaller of two time values is ordered before the larger one.

- **DATE**
  The earlier date is ordered before the more recent date.

- **ARRAY**
  Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

  If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

  Example:

  \[
  [] < ["a"] < ["ab"] < ["ab", "cd", "ef"] < ["ab", "ef"]
  \]

- **BOOLEAN**
  The JSON `false` literal is less than the JSON `true` literal.

- **OBJECT**
  Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

  Example:

  \{
  "a": 1, "b": 2
  \} = \{
  "b": 2, "a": 1
  \}

  The order of two objects that are not equal is unspecified but deterministic.

- **STRING**
  Strings are ordered lexically on the first \(N\) bytes of the `utf8mb4` representation of the two strings being compared, where \(N\) is the length of the shorter string. If the first \(N\) bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

  Example:

  \"a\" < \"ab\" < \"b\" < \"bc\"

  This ordering is equivalent to the ordering of SQL strings with collation `utf8mb4_bin`. Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case-sensitive:

  \"A\" < \"a\"
Converting between JSON and non-JSON values

• INTEGER, DOUBLE

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see Section 9.1.2, “Numeric Literals”.

The rules for comparing native MySQL numeric types are discussed in Section 12.2, “Type Conversion in Expression Evaluation”, but the rules for comparing numbers within JSON values differ somewhat:

• In a comparison between two columns that use the native MySQL INT and DOUBLE numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.

• On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers will be integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

<table>
<thead>
<tr>
<th>9.223372036854776e18</th>
<th>9223372036854775805</th>
<th>9223372036854775806</th>
<th>9223372036854775807</th>
</tr>
</thead>
<tbody>
<tr>
<td>9223372036854775805</td>
<td>9223372036854775806</td>
<td>9223372036854775807</td>
<td>9223372036854775807</td>
</tr>
<tr>
<td>9.223372036854776e18</td>
<td>9223372036854775805</td>
<td>9223372036854775806</td>
<td>9223372036854775807</td>
</tr>
</tbody>
</table>

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

• Integer comparison:

<table>
<thead>
<tr>
<th>9223372036854775805</th>
<th>9223372036854775806</th>
<th>9223372036854775807</th>
</tr>
</thead>
<tbody>
<tr>
<td>9223372036854775805</td>
<td>9223372036854775806</td>
<td>9223372036854775807</td>
</tr>
</tbody>
</table>
(not defined for 9.223372036854776e18)

• Double comparison:

<table>
<thead>
<tr>
<th>9223372036854775805</th>
<th>9223372036854775806</th>
<th>9223372036854775807</th>
<th>9.223372036854776e18</th>
</tr>
</thead>
<tbody>
<tr>
<td>9223372036854775805</td>
<td>9223372036854775806</td>
<td>9223372036854775807</td>
<td>9.223372036854776e18</td>
</tr>
</tbody>
</table>

For comparison of any JSON value to SQL NULL, the result is UNKNOWN.

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

Converting between JSON and non-JSON values

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

Table 11.3 JSON Conversion Rules

<table>
<thead>
<tr>
<th>other type</th>
<th>CAST(other type AS JSON)</th>
<th>CAST(JSON AS other type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>No change</td>
<td>No change</td>
</tr>
<tr>
<td>utf8 character type</td>
<td>The string is parsed into a JSON value.</td>
<td>The JSON value is serialized into a utf8mb4 string.</td>
</tr>
<tr>
<td>(utf8mb4, utf8, ascii)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Aggregation of JSON Values

<table>
<thead>
<tr>
<th>other type</th>
<th>CAST(other type AS JSON)</th>
<th>CAST(JSON AS other type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other character types</td>
<td>Other character encodings are implicitly converted to utf8mb4 and treated as described for utf8 character type.</td>
<td>The JSON value is serialized into a utf8mb4 string, then cast to the other character encoding. The result may not be meaningful.</td>
</tr>
<tr>
<td><strong>NULL</strong></td>
<td>Results in a NULL value of type JSON.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Geometry types</td>
<td>The geometry value is converted into a JSON document by calling ST_AsGeoJSON().</td>
<td>Illegal operation. Workaround: Pass the result of CAST(json_val AS CHAR) to ST_GeomFromGeoJSON().</td>
</tr>
<tr>
<td>All other types</td>
<td>Results in a JSON document consisting of a single scalar value.</td>
<td>Succeeds if the JSON document consists of a single scalar value of the target type and that scalar value can be cast to the target type. Otherwise, returns NULL and produces a warning.</td>
</tr>
</tbody>
</table>

**ORDER BY** and **GROUP BY** for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.
- For ascending sorts, SQL NULL orders before all JSON values, including the JSON null literal; for descending sorts, SQL NULL orders after all JSON values, including the JSON null literal.
- Sort keys for JSON values are bound by the value of the `max_sort_length` system variable, so keys that differ only after the first `max_sort_length` bytes compare as equal.
- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named `jdoc` contains JSON objects having a member consisting of an `id` key and a nonnegative value, use this expression to sort by `id` values:

```sql
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the ORDER BY, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See Section 8.3.11, “Optimizer Use of Generated Column Indexes”.

### Aggregation of JSON Values

For aggregation of JSON values, SQL NULL values are ignored as for other data types. Non-NULL values are converted to a numeric type and aggregated, except for `MIN()`, `MAX()`, and `GROUP_CONCAT()`.

The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

### 11.7 Data Type Default Values

Data type specifications can have explicit or implicit default values.

A **DEFAULT value** clause in a data type specification explicitly indicates a default value for a column. Examples:
CREATE TABLE t1 (  
i     INT DEFAULT -1,  
c  VARCHAR(10) DEFAULT '',  
price  DOUBLE(16,2) DEFAULT 0.00  
);

SERIAL DEFAULT VALUE is a special case. In the definition of an integer column, it is an alias for NOT NULL AUTO_INCREMENT UNIQUE.

Some aspects of explicit DEFAULT clause handling are version dependent, as described following.

• Handling of Explicit Defaults as of MySQL 8.0.13
• Handling of Explicit Defaults Prior to MySQL 8.0.13
• Handling of Implicit Defaults

Handling of Explicit Defaults as of MySQL 8.0.13

The default value specified in a DEFAULT clause can be a literal constant or an expression. With one exception, enclose expression default values within parentheses to distinguish them from literal constant default values. Examples:

CREATE TABLE t1 (  
    -- literal defaults  
    i INT DEFAULT 0,  
    c VARCHAR(10) DEFAULT '',  
    -- expression defaults  
    f FLOAT DEFAULT (RAND() * RAND()),  
    b BINARY(16) DEFAULT (UUID_TO_BIN(UUID())),  
    d DATE DEFAULT (CURRENT_DATE + INTERVAL 1 YEAR),  
    p POINT DEFAULT (Point(0,0)),  
    j JSON DEFAULT (JSON_ARRAY())  
);

The exception is that, for TIMESTAMP and DATETIME columns, you can specify the CURRENT_TIMESTAMP function as the default, without enclosing parentheses. See Section 11.3.4, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

The BLOB, TEXT, GEOMETRY, and JSON data types can be assigned a default value only if the value is written as an expression, even if the expression value is a literal:

• This is permitted (literal default specified as expression):

CREATE TABLE t2 (b BLOB DEFAULT ('abc'));

• This produces an error (literal default not specified as expression):

CREATE TABLE t2 (b BLOB DEFAULT 'abc');

Expression default values must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

• Literals, built-in functions (both deterministic and nondeterministic), and operators are permitted.
• Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
Handling of Explicit Defaults Prior to MySQL 8.0.13

- An expression default value cannot depend on a column that has the AUTO_INCREMENT attribute.

- An expression default value for one column can refer to other table columns, with the exception that references to generated columns or columns with expression default values must be to columns that occur earlier in the table definition. That is, expression default values cannot contain forward references to generated columns or columns with expression default values.

The ordering constraint also applies to the use of ALTER TABLE to reorder table columns. If the resulting table would have an expression default value that contains a forward reference to a generated column or column with an expression default value, the statement fails.

**Note**

If any component of an expression default value depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For CREATE TABLE ... LIKE and CREATE TABLE ... SELECT, the destination table preserves expression default values from the original table.

If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as INSERT, UPDATE, and ALTER TABLE. In this situation, if binary logging is disabled, the statement is executed as normal. If binary logging is enabled and binlog_format is set to STATEMENT, the statement is logged and executed but a warning message is written to the error log, because replication slaves might diverge. When binlog_format is set to MIXED or ROW, the statement is not executed and an error message is written to the error log.

When inserting a new row, the default value for a column with an expression default can be inserted either by omitting the column name or by specifying the column as DEFAULT (just as for columns with literal defaults):

```sql
mysql> CREATE TABLE t4 (uid BINARY(16) DEFAULT (UUID_TO_BIN(UUID())));
mysql> INSERT INTO t4 () VALUES();
mysql> INSERT INTO t4 () VALUES(DEFAULT);
mysql> SELECT BIN_TO_UUID(uid) AS uid FROM t4;
```

<table>
<thead>
<tr>
<th>uid</th>
</tr>
</thead>
<tbody>
<tr>
<td>f1109174-94c9-11e8-971d-3bf1095aa633</td>
</tr>
<tr>
<td>f110cf9a-94c9-11e8-971d-3bf1095aa633</td>
</tr>
</tbody>
</table>

However, the use of DEFAULT(col_name) to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

Not all storage engines permit expression default values. For those that do not, an ER_UNSUPPORTED_ACTION_ON_DEFAULT_VAL_GENERATED error occurs.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.2, “Type Conversion in Expression Evaluation”.

Handling of Explicit Defaults Prior to MySQL 8.0.13

With one exception, the default value specified in a DEFAULT clause must be a literal constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to
be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify `CURRENT_TIMESTAMP` as the default. See Section 11.3.4, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types cannot be assigned a default value.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.2, “Type Conversion in Expression Evaluation”.

### Handling of Implicit Defaults

If a data type specification includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as a value, MySQL defines the column with no explicit `DEFAULT` clause. Exception: If the column is defined as part of a `PRIMARY KEY` but not explicitly as `NOT NULL`, MySQL creates it as a `NOT NULL` column (because `PRIMARY KEY` columns must be `NOT NULL`).

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.

- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```sql
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```sql
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See Section 5.1.11, “Server SQL Modes”.

For a given table, the `SHOW CREATE TABLE` statement displays which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is 0, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.
• For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see Section 5.1.8, “Server System Variables”). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See Section 11.3, “Date and Time Types”.

• For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

11.8 Data Type Storage Requirements

- InnoDB Table Storage Requirements
- NDB Table Storage Requirements
- Numeric Type Storage Requirements
- Date and Time Type Storage Requirements
- String Type Storage Requirements
- Spatial Type Storage Requirements
- JSON Storage Requirements

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see Chapter 16, Alternative Storage Engines, and Section C.10.4, “Limits on Table Column Count and Row Size”.

InnoDB Table Storage Requirements

See Section 15.10, “InnoDB Row Formats” for information about storage requirements for InnoDB tables.

NDB Table Storage Requirements

Important

NDB tables use 4-byte alignment; all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an NDB table. For example, in NDB tables, the TINYINT, SMALLINT, MEDIUMINT, and INTEGER (INT) column types each require 4 bytes storage per record due to the alignment factor.
Numeric Type Storage Requirements

- Each \texttt{BIT(M)} column takes \( M \) bits of storage space. Although an individual \texttt{BIT} column is \textit{not} 4-byte aligned, \texttt{NDB} reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for \texttt{BIT} columns, then another 4 bytes for bits 33-64, and so on.

- While a \texttt{NULL} itself does not require any storage space, \texttt{NDB} reserves 4 bytes per row if the table definition contains any columns allowing \texttt{NULL}, up to 32 \texttt{NULL} columns. (If an NDB Cluster table is defined with more than 32 \texttt{NULL} columns up to 64 \texttt{NULL} columns, then 8 bytes per row are reserved.)

Every table using the \texttt{NDB} storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by \texttt{NDB}. This hidden primary key consumes 31-35 bytes per table record.

You can use the \texttt{ndb\_size.pl} Perl script to estimate \texttt{NDB} storage requirements. It connects to a current MySQL (not NDB Cluster) database and creates a report on how much space that database would require if it used the \texttt{NDB} storage engine. See Section 22.4.28, “\texttt{ndb\_size.pl} — NDBCLUSTER Size Requirement Estimator” for more information.

### Numeric Type Storage Requirements

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{TINYINT}</td>
<td>1 byte</td>
</tr>
<tr>
<td>\texttt{SMALLINT}</td>
<td>2 bytes</td>
</tr>
<tr>
<td>\texttt{MEDIUMINT}</td>
<td>3 bytes</td>
</tr>
<tr>
<td>\texttt{INT, INTEGER}</td>
<td>4 bytes</td>
</tr>
<tr>
<td>\texttt{BIGINT}</td>
<td>8 bytes</td>
</tr>
<tr>
<td>\texttt{FLOAT (p)}</td>
<td>4 bytes if ( 0 \leq p \leq 24 ), 8 bytes if ( 25 \leq p \leq 53 )</td>
</tr>
<tr>
<td>\texttt{FLOAT}</td>
<td>4 bytes</td>
</tr>
<tr>
<td>\texttt{DOUBLE [PRECISION], REAL}</td>
<td>8 bytes</td>
</tr>
<tr>
<td>\texttt{DECIMAL(M, D), NUMERIC(M, D)}</td>
<td>Varies; see following discussion</td>
</tr>
<tr>
<td>\texttt{BIT(M)}</td>
<td>approximately ((M+7)/8) bytes</td>
</tr>
</tbody>
</table>

Values for \texttt{DECIMAL} (and \texttt{NUMERIC}) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>
Date and Time Type Storage Requirements

For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required Before MySQL 5.6.4</th>
<th>Storage Required as of MySQL 5.6.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>1 byte</td>
<td>1 byte</td>
</tr>
<tr>
<td>DATE</td>
<td>3 bytes</td>
<td>3 bytes</td>
</tr>
<tr>
<td>TIME</td>
<td>3 bytes</td>
<td>3 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>DATETIME</td>
<td>8 bytes</td>
<td>5 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>4 bytes</td>
<td>4 bytes + fractional seconds storage</td>
</tr>
</tbody>
</table>

As of MySQL 5.6.4, storage for `YEAR` and `DATE` remains unchanged. However, `TIME`, `DATETIME`, and `TIMESTAMP` are represented differently. `DATETIME` is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

<table>
<thead>
<tr>
<th>Fractional Seconds Precision</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 bytes</td>
</tr>
<tr>
<td>1, 2</td>
<td>1 byte</td>
</tr>
<tr>
<td>3, 4</td>
<td>2 bytes</td>
</tr>
<tr>
<td>5, 6</td>
<td>3 bytes</td>
</tr>
</tbody>
</table>

For example, `TIME(0)`, `TIME(2)`, `TIME(4)`, and `TIME(6)` use 3, 4, 5, and 6 bytes, respectively. `TIME` and `TIME(0)` are equivalent and require the same storage.

For details about internal representation of temporal values, see MySQL Internals: Important Algorithms and Structures.

String Type Storage Requirements

In the following table, `M` represents the declared column length in characters for nonbinary string types and bytes for binary string types. `L` represents the actual length in bytes of a given string value.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(<code>M</code>)</td>
<td>The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Storage Characteristics. Otherwise, <code>M \times \nu</code> bytes, ( \leq M \leq 255 ), where ( \nu ) is the number of bytes required for the maximum-length character in the character set.</td>
</tr>
<tr>
<td>BINARY(<code>M</code>)</td>
<td><code>M</code> bytes, ( 0 \leq M \leq 255 )</td>
</tr>
<tr>
<td>VARCHAR(<code>M</code>) , VARBINARY(<code>M</code>)</td>
<td><code>L + 1</code> bytes if column values require <code>0 \sim 255</code> bytes, <code>L + 2</code> bytes if values may require more than 255 bytes</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td><code>L + 1</code> bytes, where ( L &lt; 2^8 )</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td><code>L + 2</code> bytes, where ( L &lt; 2^{16} )</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td><code>L + 3</code> bytes, where ( L &lt; 2^{24} )</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td><code>L + 4</code> bytes, where ( L &lt; 2^{32} )</td>
</tr>
</tbody>
</table>
Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is \( L \) (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires \( L \) bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a `utf8` Unicode character set, you must keep in mind that not all characters use the same number of bytes. `utf8mb3` and `utf8mb4` character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of `utf8mb3` or `utf8mb4` characters, see Section 10.9, “Unicode Support”.

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string \( L \), plus one byte to record the length of the string. For the string 'abcd', \( L \) is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of 'abcd' is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of bytes that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of characters is less. For example, `utf8mb4` characters can require up to four bytes per character, so a `VARCHAR` column that uses the `utf8mb4` character set can be declared to be a maximum of 16,383 characters. See Section C.10.4, “Limits on Table Column Count and Row Size”.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The NDB storage engine supports variable-width columns. This means that a `VARCHAR` column in an NDB Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string 'abcd' stored in a `VARCHAR(50)` column using the `latin1` character set requires 8 bytes (rather than 5 bytes for the same column value in a `MyISAM` table).

`TEXT` and `BLOB` columns are implemented differently in NDB; each row in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden table. The rows in this second table are always 2000 bytes long. This means that the size of a `TEXT` column is 256 if \( size \leq 256 \)
Spatial Type Storage Requirements

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The `LENGTH()` function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see Section 11.5.3, “Supported Spatial Data Formats”.

JSON Storage Requirements

In general, the storage requirement for a JSON column is approximately the same as for a `LONGBLOB` or `LONGTEXT` column; that is, the space consumed by a JSON document is roughly the same as it would be for the document’s string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a JSON column such that it cannot be any larger than the value of `max_allowed_packet`.

11.9 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, *, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See Section 11.1.1, “Numeric Type Overview”.

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

11.10 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>TINYINT</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>TINYINT</td>
</tr>
</tbody>
</table>
### Other Vendor Type vs MySQL Type

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER VARYING(M)</td>
<td>VARCHAR(M)</td>
</tr>
<tr>
<td>FIXED</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>FLOAT4</td>
<td>FLOAT</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INT1</td>
<td>TINYINT</td>
</tr>
<tr>
<td>INT2</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INT3</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>INT4</td>
<td>INT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>LONG VARBINARY</td>
<td>MEDIUMBLOB</td>
</tr>
<tr>
<td>LONG VARCHAR</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>LONG</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>MIDDLEINT</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>DECIMAL</td>
</tr>
</tbody>
</table>

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```sql
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-------+---------------+------+-----+---------+-------+
| Field | Type          | Null | Key | Default | Extra |
|-------+---------------+------+-----+---------+-------+
| a     | tinyint(1)    | YES  |     | NULL    |       |
| b     | double        | YES  |     | NULL    |       |
| c     | mediumtext    | YES  |     | NULL    |       |
| d     | decimal(10,0) | YES  |     | NULL    |       |
+-------+---------------+------+-----+---------+-------+
4 rows in set (0.01 sec)
```

Expressions can be used at several points in SQL statements, such as in the ORDER BY or HAVING clauses of SELECT statements, in the WHERE clause of a SELECT, DELETE, or UPDATE statement, or in SET statements. Expressions can be written using literal values, column values, NULL, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in Section 24.2, “Using Stored Routines (Procedures and Functions)”, and Section 29.4, “Adding New Functions to MySQL”. See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for a particular function or operator.

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the --sql-mode=IGNORE_SPACE option. (See Section 5.1.11, “Server SQL Modes”.) Individual client programs can
request this behavior by using the \texttt{CLIENT\_IGNORE\_SPACE} option for \texttt{mysql\_real\_connect()}. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the \texttt{mysql} program in abbreviated form. Rather than showing examples in this format:

\begin{verbatim}
mysql> SELECT MOD(29,9);
+-----------+
| mod(29,9) |
+-----------+
|    2      |
+-----------+
1 rows in set (0.00 sec)
\end{verbatim}

This format is used instead:

\begin{verbatim}
mysql> SELECT MOD(29,9);
-> 2
\end{verbatim}

### 12.1 Function and Operator Reference

#### Table 12.1 Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>

<td>CEILING()</td>
<td>Return the smallest integer value not less than the argument</td>
</tr>
<tr>
<td>CHAR()</td>
<td>Return the character for each integer passed</td>
</tr>
<tr>
<td>CHAR_LENGTH()</td>
<td>Return number of characters in argument</td>
</tr>
<tr>
<td>CHARACTER_LENGTH()</td>
<td>Synonym for CHAR_LENGTH()</td>
</tr>
<tr>
<td>CHARSET()</td>
<td>Return the character set of the argument</td>
</tr>
<tr>
<td>COALESCE()</td>
<td>Return the first non-NULL argument</td>
</tr>
<tr>
<td>COERCIBILITY()</td>
<td>Return the collation coercibility value of the string argument</td>
</tr>
<tr>
<td>COLLATION()</td>
<td>Return the collation of the string argument</td>
</tr>
<tr>
<td>COMPRESS()</td>
<td>Return result as a binary string</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>CONNECTION_ID()</td>
<td>Return the connection ID (thread ID) for the connection</td>
</tr>
<tr>
<td>CONVERT()</td>
<td>Cast a value as a certain type</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one time zone to another</td>
</tr>
<tr>
<td>COS()</td>
<td>Return the cosine</td>
</tr>
<tr>
<td>COT()</td>
<td>Return the cotangent</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>CRC32()</td>
<td>Compute a cyclic redundancy check value</td>
</tr>
<tr>
<td>CREATEASYMMETRIC_PRIV_KEY()</td>
<td>Create private key</td>
</tr>
<tr>
<td>CREATEASYMMETRIC_PUB_KEY()</td>
<td>Create public key</td>
</tr>
<tr>
<td>CREATE_DH_PARAMETERS()</td>
<td>Generate shared DH secret</td>
</tr>
<tr>
<td>CREATE_DIGEST()</td>
<td>Generate digest from string</td>
</tr>
<tr>
<td>CUME_DIST()</td>
<td>Cumulative distribution value</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_ROLE()</td>
<td>Return the current active roles</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURRENT_USER(), CURRENT_USER</td>
<td>The authenticated user name and host name</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATABASE()</td>
<td>Return the default (current) database name</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime expr</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
<tr>
<td>DECODE()</td>
<td>Decode a string encrypted using ENCODE()</td>
</tr>
<tr>
<td>DEFAULT()</td>
<td>Return the default value for a table column</td>
</tr>
<tr>
<td>DEGREES()</td>
<td>Convert radians to degrees</td>
</tr>
<tr>
<td>DENSE_RANK()</td>
<td>Rank of current row within its partition, without gaps</td>
</tr>
<tr>
<td>DES_DECRYPT()</td>
<td>Decrypt a string</td>
</tr>
<tr>
<td>DES_ENCRYPT()</td>
<td>Encrypt a string</td>
</tr>
<tr>
<td>DIV</td>
<td>Integer division</td>
</tr>
<tr>
<td>/</td>
<td>Division operator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>ENCODE()</td>
<td>Encode a string</td>
</tr>
<tr>
<td>ENCRYPT()</td>
<td>Encrypt a string</td>
</tr>
<tr>
<td>=</td>
<td>Equal operator</td>
</tr>
<tr>
<td>&lt;==&gt;</td>
<td>NULL-safe equal to operator</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>EXP()</strong></td>
<td>Raise to the power of</td>
</tr>
<tr>
<td><strong>EXPORT_SET()</strong></td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td><strong>EXTRACT()</strong></td>
<td>Extract part of a date</td>
</tr>
<tr>
<td><strong>ExtractValue()</strong></td>
<td>Extract a value from an XML string using XPath notation</td>
</tr>
<tr>
<td><strong>FIELD()</strong></td>
<td>Index (position) of first argument in subsequent arguments</td>
</tr>
<tr>
<td><strong>FIND_IN_SET()</strong></td>
<td>Index (position) of first argument within second argument</td>
</tr>
<tr>
<td><strong>FIRST_VALUE()</strong></td>
<td>Value of argument from first row of window frame</td>
</tr>
<tr>
<td><strong>FLOOR()</strong></td>
<td>Return the largest integer value not greater than the argument</td>
</tr>
<tr>
<td><strong>FORMAT()</strong></td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td><strong>FORMAT_BYTES()</strong></td>
<td>Convert byte count to value with units</td>
</tr>
<tr>
<td><strong>FORMAT_PICO_TIME()</strong></td>
<td>Convert time in picoseconds to value with units</td>
</tr>
<tr>
<td><strong>FOUND_ROWS()</strong></td>
<td>For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause</td>
</tr>
<tr>
<td><strong>FROM_BASE64()</strong></td>
<td>Decode base64 encoded string and return result</td>
</tr>
<tr>
<td><strong>FROM_DAYS()</strong></td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td><strong>FROM_UNIXTIME()</strong></td>
<td>Format Unix timestamp as a date</td>
</tr>
<tr>
<td><strong>GeomCollection()</strong></td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td><strong>GeometryCollection()</strong></td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td><strong>GET_DD_COLUMN_PRIVILEGES()</strong></td>
<td>Internal use only</td>
</tr>
<tr>
<td><strong>GET_DD_CREATE_OPTIONS()</strong></td>
<td>Internal use only</td>
</tr>
<tr>
<td><strong>GET_DD_INDEX_SUB_PART_LENGTH()</strong></td>
<td>Internal use only</td>
</tr>
<tr>
<td><strong>GET_FORMAT()</strong></td>
<td>Return a date format string</td>
</tr>
<tr>
<td><strong>GET_LOCK()</strong></td>
<td>Get a named lock</td>
</tr>
<tr>
<td><strong>&gt;</strong></td>
<td>Greater than operator</td>
</tr>
<tr>
<td><strong>&gt;=</strong></td>
<td>Greater than or equal operator</td>
</tr>
<tr>
<td><strong>GREATEST()</strong></td>
<td>Return the largest argument</td>
</tr>
<tr>
<td><strong>GROUP_CONCAT()</strong></td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td><strong>GROUPING()</strong></td>
<td>Distinguish super-aggregate ROLLUP rows from regular rows</td>
</tr>
<tr>
<td><strong>GTID_SUBSET()</strong></td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
</tr>
<tr>
<td><strong>GTID_SUBTRACT()</strong></td>
<td>Return all GTIDs in set that are not in subset.</td>
</tr>
<tr>
<td><strong>HEX()</strong></td>
<td>Hexadecimal representation of decimal or string value</td>
</tr>
<tr>
<td><strong>HOUR()</strong></td>
<td>Extract the hour</td>
</tr>
<tr>
<td><strong>ICU_VERSION()</strong></td>
<td>ICU library version</td>
</tr>
<tr>
<td><strong>IF()</strong></td>
<td>If/else construct</td>
</tr>
<tr>
<td><strong>IFNULL()</strong></td>
<td>Null if/else construct</td>
</tr>
<tr>
<td><strong>IN()</strong></td>
<td>Check whether a value is within a set of values</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>----------------------------------------------------------</td>
</tr>
<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
</tr>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
</tr>
<tr>
<td>INET6_ATON()</td>
<td>Return the numeric value of an IPv6 address</td>
</tr>
<tr>
<td>INET6_NTOA()</td>
<td>Return the IPv6 address from a numeric value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>INTERNAL_AUTO_INCREMENT()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_AVG_ROW_LENGTH()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_CHECK_TIME()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_CHECKSUM()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_DATA_FREE()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_DATA_LENGTH()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_DD_CHAR_LENGTH()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_GET_COMMENT_OR_ERROR()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_GET_VIEW_WARNING_OR_ERROR()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_INDEX_COLUMN_CARDINALITY()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_INDEX_LENGTH()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_KEYS.Disabled()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_MAX_DATA_LENGTH()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_TABLE_ROWS()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERNAL_UPDATE_TIME()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>INTERVAL()</td>
<td>Return the index of the argument that is less than the first argument</td>
</tr>
<tr>
<td>IS</td>
<td>Test a value against a boolean</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_IPV4()</td>
<td>Whether argument is an IPv4 address</td>
</tr>
<tr>
<td>IS_IPV4_COMPAT()</td>
<td>Whether argument is an IPv4-compatible address</td>
</tr>
<tr>
<td>IS_IPV4_MAPPED()</td>
<td>Whether argument is an IPv4-mapped address</td>
</tr>
<tr>
<td>IS_IPV6()</td>
<td>Whether argument is an IPv6 address</td>
</tr>
<tr>
<td>IS NOT</td>
<td>Test a value against a boolean</td>
</tr>
<tr>
<td>IS NOT NULL</td>
<td>NOT NULL value test</td>
</tr>
<tr>
<td>IS NULL</td>
<td>NULL value test</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>IS_UUID()</td>
<td>Whether argument is a valid UUID</td>
</tr>
<tr>
<td>ISNULL()</td>
<td>Test whether the argument is NULL</td>
</tr>
<tr>
<td>JSON_ARRAY()</td>
<td>Create JSON array</td>
</tr>
<tr>
<td>JSON_ARRAY_APPEND()</td>
<td>Append data to JSON document</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>JSON_ARRAY_INSERT()</td>
<td>Insert into JSON array</td>
</tr>
<tr>
<td>JSON_ARRAYAGG()</td>
<td>Return result set as a single JSON array</td>
</tr>
<tr>
<td>JSON_CONTAINS()</td>
<td>Whether JSON document contains specific object at path</td>
</tr>
<tr>
<td>JSON_CONTAINS_PATH()</td>
<td>Whether JSON document contains any data at path</td>
</tr>
<tr>
<td>JSON_DEPTH()</td>
<td>Maximum depth of JSON document</td>
</tr>
<tr>
<td>JSON_EXTRACT()</td>
<td>Return data from JSON document</td>
</tr>
<tr>
<td>JSON_INSERT()</td>
<td>Insert data into JSON document</td>
</tr>
<tr>
<td>JSON_KEYS()</td>
<td>Array of keys from JSON document</td>
</tr>
<tr>
<td>JSON_LENGTH()</td>
<td>Number of elements in JSON document</td>
</tr>
<tr>
<td>JSON_MERGE() (deprecated 8.0.3)</td>
<td>Merge JSON documents, preserving duplicate keys. Deprecated synonym for JSON_MERGE_PRESERVE()</td>
</tr>
<tr>
<td>JSON_MERGE_PATCH()</td>
<td>Merge JSON documents, replacing values of duplicate keys</td>
</tr>
<tr>
<td>JSON_MERGE_PRESERVE()</td>
<td>Merge JSON documents, preserving duplicate keys</td>
</tr>
<tr>
<td>JSON_OBJECT()</td>
<td>Create JSON object</td>
</tr>
<tr>
<td>JSON_OBJECTAGG()</td>
<td>Return result set as a single JSON object</td>
</tr>
<tr>
<td>JSON_PRETTY()</td>
<td>Print a JSON document in human-readable format</td>
</tr>
<tr>
<td>JSON_QUOTE()</td>
<td>Quote JSON document</td>
</tr>
<tr>
<td>JSON_REMOVE()</td>
<td>Remove data from JSON document</td>
</tr>
<tr>
<td>JSON_REPLACE()</td>
<td>Replace values in JSON document</td>
</tr>
<tr>
<td>JSON_SEARCH()</td>
<td>Path to value within JSON document</td>
</tr>
<tr>
<td>JSON_SET()</td>
<td>Insert data into JSON document</td>
</tr>
<tr>
<td>JSON_STORAGE_FREE()</td>
<td>Freed space within binary representation of a JSON column value following a partial update</td>
</tr>
<tr>
<td>JSON_STORAGE_SIZE()</td>
<td>Space used for storage of binary representation of a JSON document</td>
</tr>
<tr>
<td>JSON_TABLE()</td>
<td>Return data from a JSON expression as a relational table</td>
</tr>
<tr>
<td>JSON_TYPE()</td>
<td>Type of JSON value</td>
</tr>
<tr>
<td>JSON_UNQUOTE()</td>
<td>Unquote JSON value</td>
</tr>
<tr>
<td>JSON_VALID()</td>
<td>Whether JSON value is valid</td>
</tr>
<tr>
<td>LAG()</td>
<td>Value of argument from row lagging current row within partition</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td>LAST_INSERT_ID()</td>
<td>Value of the AUTOINCREMENT column for the last INSERT</td>
</tr>
<tr>
<td>LAST_VALUE()</td>
<td>Value of argument from last row of window frame</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
</tbody>
</table>
### Function and Operator Reference

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LEAD()</strong></td>
<td>Value of argument from row leading current row within partition</td>
</tr>
<tr>
<td><strong>LEAST()</strong></td>
<td>Return the smallest argument</td>
</tr>
<tr>
<td><strong>LEFT()</strong></td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td><strong>&lt;&lt;</strong></td>
<td>Left shift</td>
</tr>
<tr>
<td><strong>LENGTH()</strong></td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td><strong>&lt;</strong></td>
<td>Less than operator</td>
</tr>
<tr>
<td><strong>&lt;=</strong></td>
<td>Less than or equal operator</td>
</tr>
<tr>
<td><strong>LIKE</strong></td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td><strong>LineString()</strong></td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td><strong>LN()</strong></td>
<td>Return the natural logarithm of the argument</td>
</tr>
<tr>
<td><strong>LOAD_FILE()</strong></td>
<td>Load the named file</td>
</tr>
<tr>
<td><strong>LOCALTIME(), LOCALTIME</strong></td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td><strong>LOCALTIMESTAMP, LOCALTIMESTAMP()</strong></td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td><strong>LOCATE()</strong></td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td><strong>LOG()</strong></td>
<td>Return the natural logarithm of the first argument</td>
</tr>
<tr>
<td><strong>LOG10()</strong></td>
<td>Return the base-10 logarithm of the argument</td>
</tr>
<tr>
<td><strong>LOG2()</strong></td>
<td>Return the base-2 logarithm of the argument</td>
</tr>
<tr>
<td><strong>LOWER()</strong></td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td><strong>LPAD()</strong></td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td><strong>LTRIM()</strong></td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td><strong>MAKE_SET()</strong></td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td><strong>MAKEDATE()</strong></td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td><strong>MAKETIME()</strong></td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td><strong>MASTER_POS_WAIT()</strong></td>
<td>Block until the slave has read and applied all updates up to the specified position</td>
</tr>
<tr>
<td><strong>MATCH</strong></td>
<td>Perform full-text search</td>
</tr>
<tr>
<td><strong>MAX()</strong></td>
<td>Return the maximum value</td>
</tr>
<tr>
<td><strong>MBRContains()</strong></td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td><strong>MBRCoveredBy()</strong></td>
<td>Whether one MBR is covered by another</td>
</tr>
<tr>
<td><strong>MBR Covers()</strong></td>
<td>Whether one MBR covers another</td>
</tr>
<tr>
<td><strong>MBRDistsjoint()</strong></td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td><strong>MBREquals()</strong></td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td><strong>MBRIntersects()</strong></td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td><strong>MBROverlaps()</strong></td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td><strong>MBRTouches()</strong></td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td><strong>MBRWithin()</strong></td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>MD5()</td>
<td>Calculate MD5 checksum</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>-</td>
<td>Minus operator</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MOD()</td>
<td>Return the remainder</td>
</tr>
<tr>
<td>%, MOD</td>
<td>Modulo operator</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>NAME_CONST()</td>
<td>Cause the column to have the given name</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>NOT BETWEEN ... AND ...</td>
<td>Check whether a value is not within a range of values</td>
</tr>
<tr>
<td>!=, &lt;&gt;, NOT IN()</td>
<td>Not equal operator</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>NTH_VALUE()</td>
<td>Value of argument from N-th row of window frame</td>
</tr>
<tr>
<td>NTILE()</td>
<td>Bucket number of current row within its partition.</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td>PASSWORD()</td>
<td>Calculate and return a password string</td>
</tr>
<tr>
<td>PERCENT_RANK()</td>
<td>Percentage rank value</td>
</tr>
<tr>
<td>PERIOD_ADD()</td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td>PERIOD_DIFF()</td>
<td>Return the number of months between periods</td>
</tr>
<tr>
<td>PI()</td>
<td>Return the value of pi</td>
</tr>
<tr>
<td>+</td>
<td>Addition operator</td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>POW()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>POWER()</code></td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td><code>PS_CURRENT_THREAD_ID()</code></td>
<td>Performance Schema thread ID for current thread</td>
</tr>
<tr>
<td><code>PS_THREAD_ID()</code></td>
<td>Performance Schema thread ID for given thread</td>
</tr>
<tr>
<td><code>QUARTER()</code></td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td><code>QUOTE()</code></td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td><code>RADIANS()</code></td>
<td>Return argument converted to radians</td>
</tr>
<tr>
<td><code>RAND()</code></td>
<td>Return a random floating-point value</td>
</tr>
<tr>
<td><code>RANDOM_BYTES()</code></td>
<td>Return a random byte vector</td>
</tr>
<tr>
<td><code>RANK()</code></td>
<td>Rank of current row within its partition, with gaps</td>
</tr>
<tr>
<td><code>REGEXP()</code></td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td><code>REGEXP_INSTR()</code></td>
<td>Starting index of substring matching regular expression</td>
</tr>
<tr>
<td><code>REGEXP_LIKE()</code></td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td><code>REGEXP_REPLACE()</code></td>
<td>Replace substrings matching regular expression</td>
</tr>
<tr>
<td><code>REGEXP_SUBSTR()</code></td>
<td>Return substring matching regular expression</td>
</tr>
<tr>
<td><code>RELEASE_ALL_LOCKS()</code></td>
<td>Release all current named locks</td>
</tr>
<tr>
<td><code>RELEASE_LOCK()</code></td>
<td>Release the named lock</td>
</tr>
<tr>
<td><code>REPEAT()</code></td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td><code>REPLACE()</code></td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td><code>REVERSE()</code></td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td><code>RIGHT()</code></td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td><code>&gt;&gt;&gt;(</code></td>
<td>Right shift</td>
</tr>
<tr>
<td><code>RLIKE</code></td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td><code>ROLES_GRAPHML()</code></td>
<td>Return a GraphML document representing memory role subgraphs</td>
</tr>
<tr>
<td><code>ROUND()</code></td>
<td>Round the argument</td>
</tr>
<tr>
<td><code>ROW_COUNT()</code></td>
<td>The number of rows updated</td>
</tr>
<tr>
<td><code>ROW_NUMBER()</code></td>
<td>Number of current row within its partition</td>
</tr>
<tr>
<td><code>RPAD()</code></td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td><code>RTRIM()</code></td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td><code>SCHEMA()</code></td>
<td>Synonym for <code>DATABASE()</code></td>
</tr>
<tr>
<td><code>SEC_TO_TIME()</code></td>
<td>Converts seconds to 'HH:MM:SS' format</td>
</tr>
<tr>
<td><code>SECOND()</code></td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td><code>SESSION_USER()</code></td>
<td>Synonym for <code>USER()</code></td>
</tr>
<tr>
<td><code>SHA1()</code>, <code>SHA()</code></td>
<td>Calculate an SHA-1 160-bit checksum</td>
</tr>
<tr>
<td><code>SHA2()</code></td>
<td>Calculate an SHA-2 checksum</td>
</tr>
<tr>
<td><code>SIGN()</code></td>
<td>Return the sign of the argument</td>
</tr>
<tr>
<td><code>SIN()</code></td>
<td>Return the sine of the argument</td>
</tr>
<tr>
<td><code>SLEEP()</code></td>
<td>Sleep for a number of seconds</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SOUNDSEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>SQRT()</td>
<td>Return the square root of the argument</td>
</tr>
<tr>
<td>ST_Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>ST_AsBinary(), ST_AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>ST_AsGeoJSON()</td>
<td>Generate GeoJSON object from geometry</td>
</tr>
<tr>
<td>ST_AsText(), ST_AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>ST_Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
</tr>
<tr>
<td>ST_Buffer_Strategy()</td>
<td>Produce strategy option for ST_Buffer()</td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>ST_Contains()</td>
<td>Whether one geometry contains another</td>
</tr>
<tr>
<td>ST_ConvexHull()</td>
<td>Return convex hull of geometry</td>
</tr>
<tr>
<td>ST_Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>ST_Difference()</td>
<td>Return point set difference of two geometries</td>
</tr>
<tr>
<td>ST_Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>ST_Disjoint()</td>
<td>Whether one geometry is disjoint from another</td>
</tr>
<tr>
<td>ST_Distance()</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>ST_Distance_Sphere()</td>
<td>Minimum distance on earth between two geometries</td>
</tr>
<tr>
<td>ST_EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>ST_Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>ST_Equals()</td>
<td>Whether one geometry is equal to another</td>
</tr>
<tr>
<td>ST_ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>ST_GeoHash()</td>
<td>Produce a geohash value</td>
</tr>
<tr>
<td>ST_GeomCollFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>ST_GeometryCollectionFromText(),</td>
<td></td>
</tr>
<tr>
<td>ST_GeomCollFromText()</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>ST_GeomCollFromWKB(),</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>ST_GeometryCollectionFromWKB()</td>
<td></td>
</tr>
<tr>
<td>ST_GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>ST_GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>ST_GeomFromGeoJSON()</td>
<td>Generate geometry from GeoJSON object</td>
</tr>
<tr>
<td>ST_GeomFromText(),</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>ST_GeometryFromText()</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>ST_GeomFromWKB(),</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>ST_InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>ST_Intersection()</td>
<td>Return point set intersection of two geometries</td>
</tr>
<tr>
<td>ST_Intersects()</td>
<td>Whether one geometry intersects another</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>ST_IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>ST_IsEmpty()</td>
<td>Placeholder function</td>
</tr>
<tr>
<td>ST_IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>ST_IsValid()</td>
<td>Whether a geometry is valid</td>
</tr>
<tr>
<td>ST_LatFromGeoHash()</td>
<td>Return latitude from geohash value</td>

<tr>
<td>UNCOMPRESS()</td>
<td>Uncompress a string compressed</td>
</tr>
<tr>
<td>UNCOMPRESSED_LENGTH()</td>
<td>Return the length of a string before compression</td>
</tr>
<tr>
<td>UNHEX()</td>
<td>Return a string containing hex representation of a number</td>
</tr>
<tr>
<td>UNIX_TIMESTAMP()</td>
<td>Return a Unix timestamp</td>
</tr>
<tr>
<td>UpdateXML()</td>
<td>Return replaced XML fragment</td>
</tr>
<tr>
<td>UPPER()</td>
<td>Convert to uppercase</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>UTC_DATE()</td>
<td>Return the current UTC date</td>
</tr>
<tr>
<td>UTC_TIME()</td>
<td>Return the current UTC time</td>
</tr>
<tr>
<td>UTC_TIMESTAMP()</td>
<td>Return the current UTC date and time</td>
</tr>
<tr>
<td>UUID()</td>
<td>Return a Universal Unique Identifier (UUID)</td>
</tr>
<tr>
<td>UUID_SHORT()</td>
<td>Return an integer-valued universal identifier</td>
</tr>
<tr>
<td>UUID_TO_BIN()</td>
<td>Convert string UUID to binary</td>
</tr>
<tr>
<td>VALIDATE_PASSWORD_STRENGTH()</td>
<td>Determine strength of password</td>
</tr>
<tr>
<td>VALUES()</td>
<td>Define the values to be used during an INSERT</td>
</tr>
<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET()</td>
<td>Wait until the given GTIDs have executed on slave.</td>
</tr>
<tr>
<td>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS</td>
<td>Wait until the given GTIDs have executed on slave.</td>
</tr>
<tr>
<td>WEEK()</td>
<td>Return the week number</td>
</tr>
<tr>
<td>WEEKDAY()</td>
<td>Return the weekday index</td>
</tr>
<tr>
<td>WEEKOFYEAR()</td>
<td>Return the calendar week of the date (1-53)</td>
</tr>
<tr>
<td>WEIGHT_STRING()</td>
<td>Return the weight string for a string</td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
<tr>
<td>YEAR()</td>
<td>Return the year</td>
</tr>
<tr>
<td>YEARWEEK()</td>
<td>Return the year and week</td>
</tr>
</tbody>
</table>

12.2 Type Conversion in Expression Evaluation
Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```sql
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2, 'test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```sql
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL-safe <=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()`. To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST()` to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (real) numbers.

For information about conversion of values from one temporal type to another, see Section 11.3.6, “Conversion Between Date and Time Types”.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see Comparison and Ordering of JSON Values.
The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', '1', or '1a'.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
-> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1
```

For more information about floating-point comparisons, see Section B.6.4.8, “Problems with Floating-Point Values”.

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT`/`DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
• Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. \(D\) represents a value with a DECIMAL or string representation, and \(F\) represents a floating-point number in native binary (IEEE) format.

- \(F \rightarrow D\) conversion is done with the best possible precision, returning \(D\) as the shortest string that yields \(F\) when read back in and rounded to the nearest value in native binary format as specified by IEEE.

- \(D \rightarrow F\) conversion is done such that \(F\) is the nearest native binary number to the input decimal string \(D\).

These properties imply that \(F \rightarrow D \rightarrow F\) conversions are lossless unless \(F\) is \(-\infty, +\infty,\) or \(\text{NaN}\). The latter values are not supported because the SQL standard defines them as invalid values for \(\text{FLOAT}\) or \(\text{DOUBLE}\).

For \(D \rightarrow F \rightarrow D\) conversions, a sufficient condition for losslessness is that \(D\) uses 15 or fewer digits of precision, is not a denormal value, \(-\infty, +\infty,\) or \(\text{NaN}\). In some cases, the conversion is lossless even if \(D\) has more than 15 digits of precision, but this is not always the case.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see Section 10.4, “Connection Character Sets and Collations”.)

This means that such a conversion results in a character (nonbinary) string (a `CHAR`, `VARCHAR`, or `LONGTEXT` value), except in the case that the connection character set is set to `binary`. In that case, the conversion result is a binary string (a `BINARY`, `VARBINARY`, or `LONGBLOB` value).

For integer expressions, the preceding remarks about expression evaluation apply somewhat differently for expression assignment; for example, in a statement such as this:

```sql
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type \(\text{INT}\) or \(\text{BIGINT}\) depending on the length of the integer expression. If the maximum length of the expression does not fit in an \(\text{INT}\), \(\text{BIGINT}\) is used instead. The length is taken from the \(\text{max_length}\) value of the `SELECT` result set metadata (see Section 28.7.5, “C API Data Structures”). This means that you can force a \(\text{BIGINT}\) rather than \(\text{INT}\) by use of a sufficiently long expression:

```sql
CREATE TABLE t SELECT 000000000000000000000;
```

### 12.3 Operators

#### Table 12.2 Operators

<table>
<thead>
<tr>

<td>Check whether a value is not within a range of values</td>
</tr>
<tr>
<td>! =, &lt;&gt;</td>
<td>Not equal operator</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>+</td>
<td>Addition operator</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Right shift</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication operator</td>
</tr>
</tbody>
</table>
### 12.3.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Change the sign of the argument</td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>

The precedence of `=` depends on whether it is used as a comparison operator (==) or as an assignment operator (=). When used as a comparison operator, it has the same precedence as `<=`, `>=`, `=`, `<`, `<>`, `!=`, `IS`, `LIKE`, `REGEXP`, `IN` BETWEEN, CASE, WHEN, THEN, ELSE NOT AND, && XOR OR, || = (assignment), :=

The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical OR operator. With PIPES_AS_CONCAT enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, `!` and NOT have the same precedence.

See Section 5.1.11, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```sql
mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9
```

### 12.3.2 Comparison Functions and Operators
### Table 12.3 Comparison Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>NOT IN()</td>
<td>Check whether a value is not within a set of values</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

Comparison operations result in a value of 1 (true), 0 (false), or NULL. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

- >  <  >=  <=  <>  !=

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see Section 13.2.11.5, “Row Subqueries”.

Some of the functions in this section return values other than 1 (true), 0 (false), or NULL. LEAST() and GREATEST() are examples of such functions; Section 12.2, “Type Conversion in Expression Evaluation”, describes the rules for comparison operations performed by these and similar functions for determining their return values.
Comparison Functions and Operators

Note

In previous versions of MySQL, when evaluating an expression containing LEAST() or GREATEST(), the server attempted to guess the context in which the function was used, and to coerce the function's arguments to the data type of the expression as a whole. For example, the arguments to LEAST("11", "45", "2") are evaluated and sorted as strings, so that this expression returns "11". In MySQL 8.0.3 and earlier, when evaluating the expression LEAST("11", "45", "2") + 0, the server converted the arguments to integers (anticipating the addition of integer 0 to the result) before sorting them, thus returning 2.

Beginning with MySQL 8.0.4, the server no longer attempts to infer context in this fashion. Instead, the function is executed using the arguments as provided, performing data type conversions to one or more of the arguments if and only if they are not all of the same type. Any type coercion mandated by an expression that makes use of the return value is now performed following function execution. This means that, in MySQL 8.0.4 and later, LEAST("11", "45", "2") + 0 evaluates to "11" + 0 and thus to integer 11. (Bug #83895, Bug #25123839)

To convert a value to a specific type for comparison purposes, you can use the CAST() function. String values can be converted to a different character set using CONVERT(). See Section 12.10, “Cast Functions and Operators”.

By default, string comparisons are not case-sensitive and use the current character set. The default is utf8mb4.

- =

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

For row comparisons, (a, b) = (x, y) is equivalent to:

```
(a = x) AND (b = y)
```

- <=>

NULL-safe equal. This operator performs an equality comparison like the = operator, but returns 1 rather than NULL if both operands are NULL, and 0 rather than NULL if one operand is NULL.

The <=> operator is equivalent to the standard SQL IS NOT DISTINCT FROM operator.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```
For row comparisons, \((a, b) \leftrightarrow (x, y)\) is equivalent to:

\[
(a \leftrightarrow x) \text{ AND } (b \leftrightarrow y)
\]

- \(<\), \(!=\)

Not equal:

```sql
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zappp';
-> 1
```

For row comparisons, \((a, b) \leftrightarrow (x, y)\) and \((a, b) \not= (x, y)\) are equivalent to:

\[
(a \leftrightarrow x) \text{ OR } (b \leftrightarrow y)
\]

- \(<=\)

Less than or equal:

```sql
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons, \((a, b) \leq (x, y)\) is equivalent to:

\[
(a < x) \text{ OR } ((a = x) \text{ AND } (b \leq y))
\]

- \(<\)

Less than:

```sql
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons, \((a, b) < (x, y)\) is equivalent to:

\[
(a < x) \text{ OR } ((a = x) \text{ AND } (b < y))
\]

- \(>=\)

Greater than or equal:

```sql
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons, \((a, b) \geq (x, y)\) is equivalent to:

\[
(a > x) \text{ OR } ((a = x) \text{ AND } (b \geq y))
\]

- \(>\)
Comparison Functions and Operators

Greater than:

```sql
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons, \((a, b) > (x, y)\) is equivalent to:

\[(a > x) \lor ((a = x) \land (b > y))\]

• **IS** boolean_value

Tests a value against a boolean value, where **boolean_value** can be **TRUE**, **FALSE**, or **UNKNOWN**.

```sql
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

• **IS NOT** boolean_value

Tests a value against a boolean value, where **boolean_value** can be **TRUE**, **FALSE**, or **UNKNOWN**.

```sql
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

• **IS NULL**

Tests whether a value is **NULL**.

```sql
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using **IS NULL**:

• If **sql_auto_is_null** variable is set to 1, then after a statement that successfully inserts an automatically generated **AUTO_INCREMENT** value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the **LAST_INSERT_ID()** function. For details, including the return value after a multiple-row insert, see Section 12.15, “Information Functions”. If no **AUTO_INCREMENT** value was successfully inserted, the **SELECT** statement returns no row.

The behavior of retrieving an **AUTO_INCREMENT** value by using an **IS NULL** comparison can be disabled by setting **sql_auto_is_null = 0**. See Section 5.1.8, “Server System Variables”.

The default value of **sql_auto_is_null** is 0.

• For **DATE** and **DATETIME** columns that are declared as **NOT NULL**, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```
This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

See Obtaining Auto-Increment Values, and the description for the \texttt{FLAG\_AUTO\_IS\_NULL} option at Connector/ODBC Connection Parameters.

- \textbf{IS NOT NULL}

Tests whether a value is not \texttt{NULL}.

\begin{verbatim}
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
\end{verbatim}

- \textbf{expr BETWEEN min AND max}

If \textit{expr} is greater than or equal to \textit{min} and \textit{expr} is less than or equal to \textit{max}, BETWEEN returns \texttt{1}, otherwise it returns \texttt{0}. This is equivalent to the expression \((\text{min} \leq \text{expr} \text{ AND } \text{expr} \leq \text{max})\) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in \textsection\ 12.2, “Type Conversion in Expression Evaluation”, but applied to all the three arguments.

\begin{verbatim}
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
\end{verbatim}

For best results when using \texttt{BETWEEN} with date or time values, use \texttt{CAST()} to explicitly convert the values to the desired data type. Examples: If you compare a \texttt{DATETIME} to two \texttt{DATE} values, convert the \texttt{DATE} values to \texttt{DATETIME} values. If you use a string constant such as \texttt{'2001-1-1'} in a comparison to a \texttt{DATE}, cast the string to a \texttt{DATE}.

- \textbf{expr NOT BETWEEN min AND max}

This is the same as \texttt{NOT (expr BETWEEN min AND max)}.

- \textbf{COALESCE(value,...)}

Returns the first non-\texttt{NULL} value in the list, or \texttt{NULL} if there are no non-\texttt{NULL} values.

The return type of \texttt{COALESCE()} is the aggregated type of the argument types.

\begin{verbatim}
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
\end{verbatim}

- \textbf{GREATEST(value1,value2,...)}

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for \texttt{LEAST()}.
Comparison Functions and Operators

mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'

GREATEST() returns NULL if any argument is NULL.

- expr IN (value,...)

Returns 1 if expr is equal to any of the values in the IN list, else returns 0. If all values are constants, they are evaluated according to the type of expr and sorted. The search for the item then is done using a binary search. This means IN is very quick if the IN value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in Section 12.2, “Type Conversion in Expression Evaluation”, but applied to all the arguments.

mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1

IN can be used to compare row constructors:

mysql> SELECT (3,4) IN ((1,2), (3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
-> 0

You should never mix quoted and unquoted values in an IN list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an IN expression like this:

SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');

Instead, write it like this:

SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');

The number of values in the IN list is only limited by the max_allowed_packet value.

To comply with the SQL standard, IN returns NULL not only if the expression on the left hand side is NULL, but also if no match is found in the list and one of the expressions in the list is NULL.

IN() syntax can also be used to write certain types of subqueries. See Section 13.2.11.3, “Subqueries with ANY, IN, or SOME”.

- expr NOT IN (value,...)

This is the same as NOT (expr IN (value,...)).

- ISNULL(expr)

If expr is NULL, ISNULL() returns 1, otherwise it returns 0.
ISNULL() can be used instead of = to test whether a value is NULL. (Comparing a value to NULL using = always yields NULL.)

The ISNULL() function shares some special behaviors with the IS NULL comparison operator. See the description of IS NULL.

- **INTERVAL(N, N1, N2, N3, ...)**

Returns 0 if N < N1, 1 if N < N2 and so on or -1 if N is NULL. All arguments are treated as integers. It is required that N1 < N2 < N3 < ... < Nn for this function to work correctly. This is because a binary search is used (very fast).

- **LEAST(value1, value2, ...)**

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

  - If any argument is NULL, the result is NULL. No comparison is needed.
  - If all arguments are integer-valued, they are compared as integers.
  - If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a DECIMAL value, they are compared as DECIMAL values.
  - If the arguments comprise a mix of numbers and strings, they are compared as strings.
  - If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
  - In all other cases, the arguments are compared as binary strings.

The return type of LEAST() is the aggregated type of the comparison argument types.

### 12.3.3 Logical Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND, &amp;&amp;</td>
<td>Logical AND</td>
</tr>
</tbody>
</table>
Logical Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>OR</td>
<td>Logical OR</td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as `1` (`TRUE`), `0` (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```sql
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- **NOT, !**

  Logical NOT. Evaluates to `1` if the operand is `0`, to `0` if the operand is nonzero, and `NOT` `NULL` returns `NULL`.

```sql
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces `1` because the expression evaluates the same way as `(!!)+1`.

- **AND, &&**

  Logical AND. Evaluates to `1` if all operands are nonzero and not `NULL`, to `0` if one or more operands are `0`, otherwise `NULL` is returned.

```sql
mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0
```

- **OR, ||**

  Logical OR. When both operands are non-`NULL`, the result is `1` if any operand is nonzero, and `0` otherwise. With a `NULL` operand, the result is `1` if the other operand is nonzero, and `NULL` otherwise. If both operands are `NULL`, the result is `NULL`.
Assignment Operators

mysql> SELECT 1 OR 1;
   -> 1
mysql> SELECT 1 OR 0;
   -> 1
mysql> SELECT 0 OR 0;
   -> 0
mysql> SELECT 0 OR NULL;
   -> NULL
mysql> SELECT 1 OR NULL;
   -> 1

• XOR

Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

mysql> SELECT 1 XOR 1;
   -> 0
mysql> SELECT 1 XOR 0;
   -> 1
mysql> SELECT 1 XOR NULL;
   -> NULL
mysql> SELECT 1 XOR 1 XOR 1;
   -> 1

a XOR b is mathematically equal to (a AND (NOT b)) OR ((NOT a) and b).

12.3.4 Assignment Operators

Table 12.5 Assignment Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement)</td>
</tr>
<tr>
<td>:=</td>
<td>Assign a value</td>
</tr>
</tbody>
</table>

• :=

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same SET statement. You can perform multiple assignments in the same statement.

Unlike =, the := operator is never interpreted as a comparison operator. This means you can use := in any valid SQL statement (not just in SET statements) to assign a value to a variable.

mysql> SELECT @var1, @var2;
   -> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
   -> 1, NULL
mysql> SELECT @var1, @var2;
   -> 1, 1
mysql> SELECT @var1, @var2 := @var1;
   -> 1, 1
You can make value assignments using `:=` in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```sql
mysql> SELECT @var1:=COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

```sql
mysql> SELECT * FROM t1;
-> 1, 3, 5, 7
```

```sql
mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

```sql
mysql> SELECT @var1;
-> 1
```

```sql
mysql> SELECT * FROM t1;
-> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the `:=` operator, this is not recommended. Section 9.4, “User-Defined Variables”, explains why you should avoid doing this.

- `=`

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=`.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a comparison operator.

```sql
mysql> SELECT @var1, @var2;
-> NULL, NULL
```

```sql
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
```

```sql
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
```

For more information, see Section 13.7.5.1, “SET Syntax for Variable Assignment”, Section 13.2.12, “UPDATE Syntax”, and Section 13.2.11, “Subquery Syntax”.

### 12.4 Control Flow Functions
Table 12.6 Flow Control Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Case operator</td>
</tr>
<tr>
<td>IF()</td>
<td>If/else construct</td>
</tr>
<tr>
<td>IFNULL()</td>
<td>Null if/else construct</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
</tbody>
</table>

- CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END

CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END

The first CASE syntax returns the result for the first value=compare_value comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after ELSE is returned, or NULL if there is no ELSE part.

Note

The syntax of the CASE expr described here differs slightly from that of the SQL CASE statement described in Section 13.6.5.1, “CASE Syntax”, for use inside stored programs. The CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

The return type of a CASE expression result is the aggregated type of all result values:

- If all types are numeric, the aggregated type is also numeric:
  - If at least one argument is double precision, the result is double precision.
  - Otherwise, if at least one argument is DECIMAL, the result is DECIMAL.
  - Otherwise, the result is an integer type (with one exception):
    - If all integer types are all signed or all unsigned, the result is the same sign and the precision is the highest of all specified integer types (that is, TINYINT, SMALLINT, MEDIUMINT, INT, or BIGINT).
    - If there is a combination of signed and unsigned integer types, the result is signed and the precision may be higher. For example, if the types are signed INT and unsigned INT, the result is signed BIGINT.
    - The exception is unsigned BIGINT combined with any signed integer type. The result is DECIMAL with sufficient precision and scale 0.
  - If all types are BIT, the result is BIT. Otherwise, BIT arguments are treated similar to BIGINT.
  - If all types are YEAR, the result is YEAR. Otherwise, YEAR arguments are treated similar to INT.
  - If all types are character string (CHAR or VARCHAR), the result is VARCHAR with maximum length determined by the longest character length of the operands.
  - If all types are character or binary string, the result is VARBINARY.
Control Flow Functions

- **SET** and **ENUM** are treated similar to **VARCHAR**; the result is **VARCHAR**.
- If all types are **JSON**, the result is **JSON**.
- If all types are temporal, the result is temporal:
  - If all temporal types are **DATE**, **TIME**, or **TIMESTAMP**, the result is **DATE**, **TIME**, or **TIMESTAMP**, respectively.
  - Otherwise, for a mix of temporal types, the result is **DATETIME**.
- If all types are **GEOMETRY**, the result is **GEOMETRY**.
- If any type is **BLOB**, the result is **BLOB**.
- For all other type combinations, the result is **VARCHAR**.
- Literal **NULL** operands are ignored for type aggregation.

```sql
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
-> WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
```

- **IF(expr1, expr2, expr3)**

  If **expr1** is **TRUE** (**expr1 <> 0 and expr1 <> NULL**), **IF()** returns **expr2**. Otherwise, it returns **expr3**.

  **Note**
  
  There is also an **IF statement**, which differs from the **IF()** function described here. See Section 13.6.5.2, “IF Syntax”.

  If only one of **expr2** or **expr3** is explicitly **NULL**, the result type of the **IF()** function is the type of the non-**NULL** expression.

  The default return type of **IF()** (which may matter when it is stored into a temporary table) is calculated as follows:

  - If **expr2** or **expr3** produce a string, the result is a string.
    - If **expr2** and **expr3** are both strings, the result is case-sensitive if either string is case sensitive.
  - If **expr2** or **expr3** produce a floating-point value, the result is a floating-point value.
  - If **expr2** or **expr3** produce an integer, the result is an integer.

```sql
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2, 'yes', 'no');
-> 'yes'
mysql> SELECT IF(STRCMP('test', 'test1'), 'no', 'yes');
```
• **IFNULL**(expr1, expr2)

If `expr1` is not NULL, `IFNULL()` returns `expr1`; otherwise it returns `expr2`.

mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'

The default return type of `IFNULL(expr1, expr2)` is the more “general” of the two expressions, in the order STRING, REAL, or INTEGER. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-------+--------------+------+-----+---------+-------+
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>varbinary(4)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
+-------+--------------+------+-----+---------+-------+

In this example, the type of the `test` column is `VARBINARY(4)` (a string type).

• **NULLIF**(expr1, expr2)

Returns NULL if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

The return value has the same type as the first argument.

mysql> SELECT NULLIF(1,1);  
-> NULL
mysql> SELECT NULLIF(1,2);  
-> 1

Note
MySQL evaluates `expr1` twice if the arguments are not equal.

### 12.5 String Functions

**Table 12.7 String Operators**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII()</td>
<td>Return numeric value of left-most character</td>
</tr>
<tr>
<td>BIN()</td>
<td>Return a string containing binary representation of a number</td>
</tr>
<tr>
<td>BIT_LENGTH()</td>
<td>Return length of argument in bits</td>
</tr>
<tr>
<td>CHAR()</td>
<td>Return the character for each integer passed</td>
</tr>
<tr>
<td>CHAR_LENGTH()</td>
<td>Return number of characters in argument</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CHARACTER_LENGTH()</td>
<td>Synonym for CHAR_LENGTH()</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Index (position) of first argument in subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Index (position) of first argument within second argument</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>FROM_BASE64()</td>
<td>Decode base64 encoded string and return result</td>
</tr>
<tr>
<td>HEX()</td>
<td>Hexadecimal representation of decimal or string value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td>LEFT()</td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td>LENGTH()</td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>LOAD_FILE()</td>
<td>Load the named file</td>
</tr>
<tr>
<td>LOCATE()</td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td>MATCH</td>
<td>Perform full-text search</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT_REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REGEXP_INSTR()</td>
<td>Starting index of substring matching regular expression</td>
</tr>
<tr>
<td>REGEXP_LIKE()</td>
<td>Whether string matches regular expression</td>
</tr>
</tbody>
</table>
### String Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REGEXP_REPLACE()</td>
<td>Replace substrings matching regular expression</td>
</tr>
<tr>
<td>REGEXP_SUBSTR()</td>
<td>Return substring matching regular expression</td>
</tr>
<tr>
<td>REPEAT()</td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td>REPLACE()</td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td>REVERSE()</td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td>RIGHT()</td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>RPAD()</td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td>RTRIM()</td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td>SOUNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
<tr>
<td>SUBSTR()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING_INDEX()</td>
<td>Return a substring from a string before the specified number of occurrences of the delimiter</td>
</tr>
<tr>
<td>TO_BASE64()</td>
<td>Return the argument converted to a base-64 string</td>
</tr>
<tr>
<td>TRIM()</td>
<td>Remove leading and trailing spaces</td>
</tr>
<tr>
<td>UCASE()</td>
<td>Synonym for UPPER()</td>
</tr>
<tr>
<td>UNHEX()</td>
<td>Return a string containing hex representation of a number</td>
</tr>
<tr>
<td>UPPER()</td>
<td>Convert to uppercase</td>
</tr>
<tr>
<td>WEIGHT_STRING()</td>
<td>Return the weight string for a string</td>
</tr>
</tbody>
</table>

String-valued functions return **NULL** if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 5.1.1, “Configuring the Server”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- **ASCII**(*str*)

  Returns the numeric value of the leftmost character of the string *str*. Returns 0 if *str* is the empty string. Returns **NULL** if *str* is **NULL**. **ASCII()** works for 8-bit characters.

```plaintext
mysql> SELECT ASCII('2');
    -> 50
mysql> SELECT ASCII(2);
    -> 50
mysql> SELECT ASCII('dx');
    -> 100
```

See also the **ORD()** function.

- **BIN**(N)
String Functions

Returns a string representation of the binary value of \( N \), where \( N \) is a longlong (BIGINT) number. This is equivalent to \texttt{CONV}(N, 10, 2). Returns NULL if \( N \) is NULL.

\begin{verbatim}
mysql> SELECT BIN(12);
-> '1100'
\end{verbatim}

- \texttt{BIT_LENGTH(str)}

Returns the length of the string \texttt{str} in bits.

\begin{verbatim}
mysql> SELECT BIT_LENGTH('text');
-> 32
\end{verbatim}

- \texttt{CHAR(N, ... [USING charset_name])}

\texttt{CHAR()} interprets each argument \( N \) as an integer and returns a string consisting of the characters given by the code values of those integers. NULL values are skipped.

\begin{verbatim}
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
-> 'MMM'
\end{verbatim}

\texttt{CHAR()} arguments larger than 255 are converted into multiple result bytes. For example, \texttt{CHAR(256)} is equivalent to \texttt{CHAR(1,0)}, and \texttt{CHAR(256*256)} is equivalent to \texttt{CHAR(1,0,0)}:

\begin{verbatim}
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+----------------+----------------+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+----------------+----------------+
| 0100           | 0100           |
+----------------+----------------+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+------------------+--------------------+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+------------------+--------------------+
| 010000           | 010000             |
+------------------+--------------------+
\end{verbatim}

By default, \texttt{CHAR()} returns a binary string. To produce a string in a given character set, use the optional \texttt{USING} clause:

\begin{verbatim}
mysql> SELECT CHARSET(CHAR('x'65')), CHARSET(CHAR('x'65' USING utf8));
+----------------+---------------------------------+
| CHARSET(CHAR('x'65')) | CHARSET(CHAR('x'65' USING utf8)) |
+----------------+---------------------------------+
| binary         | utf8                            |
+----------------+---------------------------------+
\end{verbatim}

If \texttt{USING} is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from \texttt{CHAR()} becomes NULL.

- \texttt{CHAR_LENGTH(str)}

Returns the length of the string \texttt{str}, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, \texttt{LENGTH()} returns 10, whereas \texttt{CHAR_LENGTH()} returns 5.
• **CHARACTER_LENGTH**(str)

  **CHARACTER_LENGTH()** is a synonym for **CHAR_LENGTH()**.

• **CONCAT**(str1,str2,...)

  Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

  **CONCAT()** returns **NULL** if any argument is **NULL**.

```sql
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```sql
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

• **CONCAT_WS**(separator,str1,str2,...)

  **CONCAT_WS()** stands for Concatenate With Separator and is a special form of **CONCAT()**. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is **NULL**, the result is **NULL**.

```sql
mysql> SELECT CONCAT_WS(',','First name','Second name','Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',','First name',NULL,'Last Name');
-> 'First name,Last Name'
```

**CONCAT_WS()** does not skip empty strings. However, it does skip any **NULL** values after the separator argument.

• **ELT**(N,str1,str2,str3,...)

  **ELT()** returns the **N**th element of the list of strings: *str1* if *N* = 1, *str2* if *N* = 2, and so on. Returns **NULL** if *N* is less than 1 or greater than the number of arguments. **ELT()** is the complement of **FIELD()**.

```sql
mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Aa'
mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Dd'
```

• **EXPORT_SET**(bits,on,off[,separator[,number_of_bits]])

  Returns a string such that for every bit set in the value *bits*, you get an **on** string and for every bit not set in the value, you get an **off** string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the **separator** string (the default being the comma character , ). The number of bits examined is given by **number_of_bits**, if present.
String Functions

which has a default of 64 if not specified. `number_of_bits` is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of −1 is effectively the same as 64.

```sql
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10);
-> '0,1,1,0,0,0,0,0,0,0'
```

- **FIELD(str, str1, str2, str3, ...)**

Returns the index (position) of `str` in the `str1, str2, str3, ...` list. Returns 0 if `str` is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If `str` is NULL, the return value is 0 because NULL fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```sql
mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 2
mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 0
```

- **FIND_IN_SET(str, strlist)**

Returns a value in the range of 1 to `N` if the string `str` is in the string list `strlist` consisting of `N` substrings. A string list is a string composed of substrings separated by `,` characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if `str` is not in `strlist` or if `strlist` is the empty string. Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (,) character.

```sql
mysql> SELECT FIND_IN_SET('b','a,b,c,d');
-> 2
```

- **FORMAT(X, D[,locale])**

Formats the number `X` to a format like '##,###,##.##', rounded to `D` decimal places, and returns the result as a string. If `D` is 0, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number’s decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable (see Section 10.15, “MySQL Server Locale Support”). If no locale is specified, the default is 'en_US'.

```sql
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1,4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2,0);
-> '12,332'
mysql> SELECT FORMAT(12332.2,2,'de_DE');
-> '12.332,20'
```

- **FROM_BASE64(str)**

Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` and returns the decoded result as a binary string. The result is `NULL` if the argument is `NULL` or not a valid base-64 string. See the description of `TO_BASE64()` for details about the encoding and decoding rules.

```sql
SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
```

```
-> 'JWJj', 'abc'
```

- **HEX(str), HEX(N)**

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

```sql
SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
```

```
-> 'abc', 616263, 'abc'
```

```sql
SELECT HEX(255), CONV(HEX(255),16,10);
```

```
-> 'FF', 255
```

- **INSERT(str,pos,len,newstr)**

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```sql
SELECT INSERT('Quadratic', 3, 4, 'What');
```

```
-> 'QuWhattic'
```

```sql
SELECT INSERT('Quadratic', -1, 4, 'What');
```

```
-> 'Quadratic'
```

```sql
SELECT INSERT('Quadratic', 3, 100, 'What');
```

```
-> 'QuWhat'
```

This function is multibyte safe.

- **INSTR(str,substr)**

Returns the position of the first occurrence of substring `substr` in string `str`. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```sql
SELECT INSTR('foobarbar', 'bar');
```

```
-> 4
```

```sql
SELECT INSTR('xbar', 'foobar');
```

```
-> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- **LCASE(str)**

`LCASE()` is a synonym for `LOWER()`.

`LCASE()` used in a view is rewritten as `LOWER()` when storing the view’s definition. (Bug #12844279)
String Functions

- **LEFT(str, len)**
  Returns the leftmost len characters from the string str, or NULL if any argument is NULL.

  ```
  mysql> SELECT LEFT('foobarbar', 5);
  -> 'fooba'
  ```
  This function is multibyte safe.

- **LENGTH(str)**
  Returns the length of the string str, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, LENGTH() returns 10, whereas CHAR_LENGTH() returns 5.

  ```
  mysql> SELECT LENGTH('text');
  -> 4
  ```

  **Note**
  The Length() OpenGIS spatial function is named ST_Length() in MySQL.

- **LOAD_FILE(file_name)**
  Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the FILE privilege. The file must be readable by all and its size less than max_allowed_packet bytes. If the secure_file_priv system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

  If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns NULL.

  The character_set_filesystem system variable controls interpretation of file names that are given as literal strings.

  ```
  mysql> UPDATE t
  SET blob_col=LOAD_FILE('/tmp/picture')
  WHERE id=1;
  ```

- **LOCATE(substr, str)**, **LOCATE(substr, str, pos)**
  The first syntax returns the position of the first occurrence of substring substr in string str. The second syntax returns the position of the first occurrence of substring substr in string str, starting at position pos. Returns 0 if substr is not in str. Returns NULL if any argument is NULL.

  ```
  mysql> SELECT LOCATE('bar', 'foobarbar');
  -> 4
  mysql> SELECT LOCATE('xbar', 'foobar');
  -> 0
  mysql> SELECT LOCATE('bar', 'foobarbar', 5);
  -> 7
  ```
  This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- **LOWER(str)**
Returns the string \texttt{str} with all characters changed to lowercase according to the current character set mapping. The default is \texttt{utf8mb4}.

\begin{verbatim}
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
\end{verbatim}

\texttt{LOWER()} (and \texttt{UPPER()}) are ineffective when applied to binary strings (\texttt{BINARY}, \texttt{VARBINARY}, \texttt{BLOB}). To perform lettercase conversion, convert the string to a nonbinary string:

\begin{verbatim}
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-------------+------------------------------------+
<table>
<thead>
<tr>
<th>LOWER(@str)</th>
<th>LOWER(CONVERT(@str USING utf8mb4))</th>
</tr>
</thead>
<tbody>
<tr>
<td>New York</td>
<td>new york</td>
</tr>
</tbody>
</table>
+-------------+------------------------------------+
\end{verbatim}

For collations of Unicode character sets, \texttt{LOWER()} and \texttt{UPPER()} work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, \texttt{utf8mb4_0900_ai_ci} and \texttt{utf8_unicode_520_ci} work according to UCA 9.0.0 and 5.2.0, respectively, whereas \texttt{utf8_unicode_ci} works according to UCA 4.0.0. See Section 10.10.1, "Unicode Character Sets".

This function is multibyte safe.

\texttt{LCASE()} used within views is rewritten as \texttt{LOWER()}.

- \texttt{LPAD(str,len,padstr)}

Returns the string \texttt{str}, left-padded with the string \texttt{padstr} to a length of \texttt{len} characters. If \texttt{str} is longer than \texttt{len}, the return value is shortened to \texttt{len} characters.

\begin{verbatim}
mysql> SELECT LPAD('hi',4,'??');
-> '??hi'
mysql> SELECT LPAD('hi',1,'??');
-> 'h'
\end{verbatim}

- \texttt{LTRIM(str)}

Returns the string \texttt{str} with leading space characters removed.

\begin{verbatim}
mysql> SELECT LTRIM('  barbar');
-> 'barbar'
\end{verbatim}

This function is multibyte safe.

- \texttt{MAKE_SET(bits,str1,str2,...)}

Returns a set value (a string containing substrings separated by \texttt{,} characters) consisting of the strings that have the corresponding bit in \texttt{bits} set. \texttt{str1} corresponds to bit 0, \texttt{str2} to bit 1, and so on. NULL values in \texttt{str1}, \texttt{str2}, ... are not appended to the result.

\begin{verbatim}
mysql> SELECT MAKE_SET(1,'a','b','c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
-> 'hello,world'
\end{verbatim}
String Functions

```sql
mysql> SELECT MAKE_SET(1 | 4, 'hello', 'nice', NULL, 'world');
-> 'hello'
mysql> SELECT MAKE_SET(0, 'a', 'b', 'c');
-> ''
```

- **MID**(str, pos, len)

  **MID**(str, pos, len) is a synonym for SUBSTRING(str, pos, len).

- **OCT**(N)

  Returns a string representation of the octal value of N, where N is a longlong (BIGINT) number. This is equivalent to CONV(N, 10, 8). Returns NULL if N is NULL.

  ```sql
  mysql> SELECT OCT(12);
  -> '14'
  ```

- **OCTET_LENGTH**(str)

  **OCTET_LENGTH**(str) is a synonym for LENGTH().

- **ORD**(str)

  If the leftmost character of the string str is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

  \[
  \text{(1st byte code)} + (2\text{nd byte code } \times 256) + (3\text{rd byte code } \times 256^2) \ldots
  \]

  If the leftmost character is not a multibyte character, ORD() returns the same value as the ASCII() function.

  ```sql
  mysql> SELECT ORD('2');
  -> 50
  ```

- **POSITION**(substr IN str)

  **POSITION**(substr IN str) is a synonym for LOCATE(substr, str).

- **QUOTE**(str)

  Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (\), single quote (‘), ASCII NULL, and Control+Z preceded by a backslash. If the argument is NULL, the return value is the word “NULL” without enclosing single quotation marks.

  ```sql
  mysql> SELECT QUOTE('Don\'t!');
  -> 'Don\'t!'
  mysql> SELECT QUOTE(NULL);
  -> NULL
  ```

  For comparison, see the quoting rules for literal strings and within the C API in Section 9.1.1, “String Literals”, and Section 28.7.7.56, “mysql_real_escape_string_quote()”.

- **REPEAT**(str, count)
Returns a string consisting of the string $str$ repeated $count$ times. If $count$ is less than 1, returns an empty string. Returns NULL if $str$ or $count$ are NULL.

```sql
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- **REPLACE($str, from_str, to_str)**

Returns the string $str$ with all occurrences of the string $from_str$ replaced by the string $to_str$. REPLACE() performs a case-sensitive match when searching for $from_str$.

```sql
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- **REVERSE($str)**

Returns the string $str$ with the order of the characters reversed.

```sql
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- **RIGHT($str, len)**

Returns the rightmost $len$ characters from the string $str$, or NULL if any argument is NULL.

```sql
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multibyte safe.

- **RPAD($str, len, padstr)**

Returns the string $str$, right-padded with the string $padstr$ to a length of $len$ characters. If $str$ is longer than $len$, the return value is shortened to $len$ characters.

```sql
mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
-> 'h'
```

This function is multibyte safe.

- **RTRIM($str)**

Returns the string $str$ with trailing space characters removed.

```sql
mysql> SELECT RTRIM('barbar   ');
-> 'barbar'
```

This function is multibyte safe.
String Functions

- **SOUNDEX(str)**

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the SOUNDEX() function returns an arbitrarily long string. You can use SUBSTRING() on the result to get a standard soundex string. All nonalphanumeric characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

**Important**

When using SOUNDEX(), you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including utf-8. See Bug #22638 for more information.

```sql
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

**Note**

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- **expr1 SOUNDS LIKE expr2**

This is the same as SOUNDEX(expr1) = SOUNDEX(expr2).

- **SPACE(N)**

Returns a string consisting of *N* space characters.

```sql
mysql> SELECT SPACE(6);
-> '        '
```

- **SUBSTR(str,pos), SUBSTR(str FROM pos), SUBSTR(str,pos,len), SUBSTR(str FROM pos FOR len)**

SUBSTR() is a synonym for SUBSTRING().

- **SUBSTRING(str,pos), SUBSTRING(str FROM pos), SUBSTRING(str,pos,len), SUBSTRING(str FROM pos FOR len)**

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*. The forms that use FROM are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function.
For all forms of \texttt{SUBSTRING()}, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

\begin{verbatim}
mysql> SELECT SUBSTRING('Quadratically', 5);
-> 'ratically'

mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'

mysql> SELECT SUBSTRING('Quadratically', 5, 6);
-> 'ratica'

mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'

mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'

mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
\end{verbatim}

This function is multibyte safe.

If \texttt{len} is less than 1, the result is the empty string.

\begin{itemize}
\item \texttt{SUBSTRING_INDEX(str, delim, count)}
\end{itemize}

Returns the substring from string \texttt{str} before \texttt{count} occurrences of the delimiter \texttt{delim}. If \texttt{count} is positive, everything to the left of the final delimiter (counting from the left) is returned. If \texttt{count} is negative, everything to the right of the final delimiter (counting from the right) is returned. \texttt{SUBSTRING_INDEX()} performs a case-sensitive match when searching for \texttt{delim}.

\begin{verbatim}
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'

mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
\end{verbatim}

This function is multibyte safe.

\begin{itemize}
\item \texttt{TO_BASE64(str)}
\end{itemize}

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is \texttt{NULL} if the argument is \texttt{NULL}. Base-64 encoded strings can be decoded using the \texttt{FROM_BASE64()} function.

\begin{verbatim}
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
\end{verbatim}

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by \texttt{TO_BASE64()} and \texttt{FROM_BASE64()}:

\begin{itemize}
\item The encoding for alphabet value 62 is '+'.
\item The encoding for alphabet value 63 is '/'.
\item Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with '=' characters to a length of 4.
\item A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
\end{itemize}
String Functions

- Decoding recognizes and ignores newline, carriage return, tab, and space.

- `TRIM( (BOTH | LEADING | TRAILING) [remstr] FROM str), TRIM([remstr FROM] str)`

  Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM('  bar  ');
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxxyz');
-> 'barx'
```

This function is multibyte safe.

- `UCASE(str)`

  `UCASE()` is a synonym for `UPPER()`.

  `UCASE()` used within views is rewritten as `UPPER()`.

- `UNHEX(str)`

  For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'
```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is `NULL`:

```
mysql> SELECT UNHEX('GG');
+-------------+
| UNHEX('GG') |
| NULL        |
+-------------+
```

A `NULL` result can occur if the argument to `UNHEX()` is a `BINARY` column, because values are padded with 0x00 bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a `CHAR(3)` column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so `UNHEX()` for the column value returns 'A'. By contrast '41' is stored into a `BINARY(3)` column as '41\0' and retrieved as '41\0' (with the trailing pad 0x00 byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns `NULL`. 

For a numeric argument \(N\), the inverse of \(\text{HEX}(N)\) is not performed by \(\text{UNHEX()}\). Use \(\text{CONV(HEX}(N),16,10)\) instead. See the description of \(\text{HEX()}\).

- \(\text{UPPER}(str)\)

Returns the string \(str\) with all characters changed to uppercase according to the current character set mapping. The default is utf8mb4.

```
mysql> SELECT UPPER('Hej');
-> 'HEJ'
```

See the description of \(\text{LOWER()}\) for information that also applies to \(\text{UPPER()}\). This included information about how to perform lettercase conversion of binary strings (\(\text{BINARY, VARBINARY, BLOB}\)) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multibyte safe.

\(\text{UCASE()}\) used within views is rewritten as \(\text{UPPER()}\).

- \(\text{WEIGHT_STRING}(str \ [AS \ \text{(CHAR|BINARY)}(N) \ [flags]})\)

This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string. It has these properties:

- If \(\text{WEIGHT_STRING}(str1) = \text{WEIGHT_STRING}(str2)\), then \(str1 = str2\) (\(str1\) and \(str2\) are considered equal)

- If \(\text{WEIGHT_STRING}(str1) < \text{WEIGHT_STRING}(str2)\), then \(str1 < str2\) (\(str1\) sorts before \(str2\))

\(\text{WEIGHT_STRING()}\) is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See Section 10.13, “Adding a Collation to a Character Set”.

This list briefly summarizes the arguments. More details are given in the discussion following the list.

- \(str\): The input string expression.

- \(AS\) clause: Optional; cast the input string to a given type and length.

- \(flags\): Optional; unused.

The input string, \(str\), is a string expression. If the input is a nonbinary (character) string such as a \(\text{CHAR, VARCHAR, or TEXT}\) value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a \(\text{BINARY, VARBINARY, or BLOB}\) value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is \(\text{NULL}\), \(\text{WEIGHT_STRING()}\) returns \(\text{NULL}\).

Examples:

```
mysql> SET @s = _utf8mb4 'AB' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+------+---------+------------------------+
| AB   | 4142    | 1C471C60               |
```

1847
The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```
mysql> SET @s = CONVERT(X'C39F' USING utf8) COLLATE utf8_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
+-------------------------------------+
<table>
<thead>
<tr>
<th>HEX(WEIGHT_STRING(@s))</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FEA0FEA</td>
</tr>
</tbody>
</table>
+-------------------------------------+
```

For non-`NULL` return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- `AS CHAR(N)` casts the string to a nonbinary string and pads it on the right with spaces to a length of `N` characters. `N` must be at least 1. If `N` is less than the length of the input string, the string is truncated to `N` characters. No warning occurs for truncation.
- `AS BINARY(N)` is similar but casts the string to a binary string, `N` is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).
12.5.1 String Comparison Functions

Table 12.8 String Comparison Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- \textit{expr LIKE pat [ESCAPE 'escape_char']}

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either \textit{expr} or \textit{pat} is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, \textit{LIKE} performs matching on a per-character basis, thus it can produce results different from the \textit{=} comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----------------------------------------+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
| 0 |                                  |
+-----------------------------------------+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+--------------------------------------+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
| 1 |                                  |
+--------------------------------------+
```

In particular, trailing spaces are significant, which is not true for \textit{CHAR} or \textit{VARCHAR} comparisons performed with the \textit{=} operator.

The \textit{flags} clause currently is unused.
String Comparison Functions

With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed.

- `\%` matches one `%` character.
- `\_` matches one `_` character.

To specify a different escape character, use the `ESCAPE` clause:

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.
Because MySQL uses C escape syntax in strings (for example, `\n` to represent a newline character), you must double any `\` that you use in `LIKE` strings. For example, to search for `\n`, specify it as `\\n`. To search for `\`, specify it as `\\\`; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
+--------------+
| filename     |
+--------------+
| C:           |
| C:\          |
| C:\Programs  |
| C:\Programs\|
+--------------+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+--------------+---------------------+
| filename     | filename LIKE '%\\' |
+--------------+---------------------+
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\|                     1 |
+--------------+---------------------+
```

```
mysql> SELECT filename, filename LIKE '%\\\\' FROM t1;
+--------------+-----------------------+
| filename     | filename LIKE '%\\\\' |
+--------------+-----------------------+
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\|                     1 |
+--------------+-----------------------+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

  This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

**Note**

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```
The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1, expr2)`

`STRCMP()` returns 0 if the strings are the same, −1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
  -> -1
mysql> SELECT STRCMP('text2', 'text');
  -> 1
mysql> SELECT STRCMP('text', 'text');
  -> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+------------------+------------------+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+------------------+------------------+
|                0 |               -1 |
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See Section 10.8.4, “Collation Coercibility in Expressions”.

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
-->
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (utf8mb4_0900_ai_ci, IMPLICIT) and (utf8mb4_0900_as_cs, IMPLICIT) for operation 'strcmp'
```

12.5.2 Regular Expressions
A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the functions and operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also Section 3.3.4.7, “Pattern Matching”.

MySQL implements regular expression support using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe. (Prior to MySQL 8.0.4, MySQL used Henry Spencer's implementation of regular expressions, which operates in byte-wise fashion and is not multibyte safe. For information about ways in which applications that use regular expressions may be affected by the implementation change, see Regular Expression Compatibility Considerations.)

### Regular Expression Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REGEXP_INSTR()</td>
<td>Starting index of substring matching regular expression</td>
</tr>
<tr>
<td>REGEXP_LIKE()</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REGEXP_REPLACE()</td>
<td>Replace substrings matching regular expression</td>
</tr>
<tr>
<td>REGEXP_SUBSTR()</td>
<td>Return substring matching regular expression</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
</tbody>
</table>

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

#### Regular Expression Functions and Operators

- `expr NOT REGEXP pat, expr NOT RLIKE pat`
  
  This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`
  
  Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If `expr` or `pat` is NULL, the return value is NULL.

`REGEXP` and `RLIKE` are synonyms for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```sql
mysql> SELECT 'Michael!' REGEXP '.*';
+------------------------+
| 'Michael!' REGEXP '.*' |
+------------------------+
|                      1 |
+------------------------+
mysql> SELECT 'new
*line' REGEXP 'new\.*\*line';
+---------------------------------------+
| 'new\n*line' REGEXP 'new\.*\*line' |
+---------------------------------------+
|                                     0 |
+---------------------------------------+
```
Regular Expressions

mysql> SELECT 'a' REGEXP '^[a-d]';
+---------------------+
| 'a' REGEXP '^[a-d]' |
|                     |
|                   1 |
+---------------------+

mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+----------------+-----------------------+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
|              1 |                     0 |
+----------------+-----------------------+

REGEXP_INSTR(expr, pat[, pos[, occurrence[, return_option[, match_type]]]])

Returns the starting index of the substring of the string expr that matches the regular expression specified by the pattern pat; 0 if there is no match. If expr or pat is NULL, the return value is NULL. Character indexes begin at 1.

REGEXP_INSTR() takes these optional arguments:

• pos: The position in expr at which to start the search. If omitted, the default is 1.

• occurrence: Which occurrence of a match to search for. If omitted, the default is 1.

• return_option: Which type of position to return. If this value is 0, REGEXP_INSTR() returns the position of the matched substring's first character. If this value is 1, REGEXP_INSTR() returns the position following the matched substring. If omitted, the default is 0.

• match_type: A string that specifies how to perform matching. The meaning is as described for REGEXP_LIKE().

For additional information about how matching occurs, see the description for REGEXP_LIKE().

mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog');
+------------------------------------+
| REGEXP_INSTR('dog cat dog', 'dog') |
|                                  1 |
+------------------------------------+

mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog', 2);
+---------------------------------------+
| REGEXP_INSTR('dog cat dog', 'dog', 2) |
|                                     9 |
+---------------------------------------+

mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{2}');
+-------------------------------------+
| REGEXP_INSTR('aa aaa aaaa', 'a{2}') |
|                                   1 |
+-------------------------------------+

mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{4}');
+-------------------------------------+
| REGEXP_INSTR('aa aaa aaaa', 'a{4}') |
|                                   8 |
+-------------------------------------+

REGEXP_LIKE(expr, pat[, match_type])
Returns 1 if the string $expr$ matches the regular expression specified by the pattern $pat$, 0 otherwise. If $expr$ or $pat$ is NULL, the return value is NULL.

The pattern can be an extended regular expression, the syntax for which is discussed in Regular Expression Syntax. The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

The optional $match_type$ argument is a string that may contain any or all of the following characters specifying how to perform matching:

- **c**: Case sensitive matching.
- **i**: Case insensitive matching.
- **m**: Multiple-line mode. Recognize line terminators within the string. The default behavior is to match line terminators only at the start and end of the string expression.
- **n**: The . character matches line terminators. The default is for . matching to stop at the end of a line.
- **u**: Unix-only line endings. Only the newline character is recognized as a line ending by the ., ^, and $ match operators.

If characters specifying contradictory options are specified within $match_type$, the rightmost one takes precedence.

By default, regular expression operations use the character set and collation of the $expr$ and $pat$ arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in Section 10.8.4, “Collation Coercibility in Expressions”. Arguments may be specified with explicit collation indicators to change comparison behavior.

```
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE');
+---------------------------------------+
| REGEXP_LIKE('CamelCase', 'CAMELCASE') |
+---------------------------------------+
|                                     1 |
+---------------------------------------+

mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs);
+------------------------------------------------------------------+
| REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs) |
+------------------------------------------------------------------+
|                                                                0 |
+------------------------------------------------------------------+
```

$match_type$ may be specified with the **c** or **i** characters to override the default case sensitivity.

Exception: If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings, even if $match_type$ contains the **i** character.

**Note**

Because MySQL uses the C escape syntax in strings (for example, \n to represent the newline character), you must double any \ that you use in your $expr$ and $pat$ arguments.

```
mysql> SELECT REGEXP_LIKE('Michael!', '.*');
+-------------------------------+
```
Regular Expressions

```sql
mysql> SELECT REGEXP_LIKE('new\n*line', 'new\.*\.*line');
<table>
<thead>
<tr>
<th>REGEXP_LIKE('new\n<em>line', 'new.</em>.*line')</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
mysql>
```

```sql
mysql> SELECT REGEXP_LIKE('a', '^[a-d]');
<table>
<thead>
<tr>
<th>REGEXP_LIKE('a', '^[a-d]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT REGEXP_LIKE('abc', 'ABC'), REGEXP_LIKE('abc', BINARY 'A');
<table>
<thead>
<tr>
<th>REGEXP_LIKE('abc', 'ABC')</th>
<th>REGEXP_LIKE('abc', BINARY 'A')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT REGEXP_REPLACE('a b c', 'b', 'X');
<table>
<thead>
<tr>
<th>REGEXP_REPLACE('a b c', 'b', 'X')</th>
</tr>
</thead>
<tbody>
<tr>
<td>a X c</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3);
```

• `REGEXP_REPLACE(expr, pat, repl[, pos[, occurrence[, match_type]]])` |

Replaces occurrences in the string `expr` that match the regular expression specified by the pattern `pat` with the replacement string `repl`, and returns the resulting string. If `expr`, `pat`, or `repl` is NULL, the return value is NULL.

`REGEXP_REPLACE()` takes these optional arguments:

• `pos`: The position in `expr` at which to start the search. If omitted, the default is 1.

• `occurrence`: Which occurrence of a match to replace. If omitted, the default is 0 (which means “replace all occurrences”).

• `match_type`: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.
Regular Expressions

<table>
<thead>
<tr>
<th>REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc def X</td>
</tr>
</tbody>
</table>

- **REGEXP_SUBSTR(expr, pat[, pos[, occurrence[, match_type]]])**

  Returns the substring of the string `expr` that matches the regular expression specified by the pattern `pat`. NULL if there is no match. If `expr` or `pat` is NULL, the return value is NULL.

  **REGEXP_SUBSTR()** takes these optional arguments:

  - **pos**: The position in `expr` at which to start the search. If omitted, the default is 1.
  - **occurrence**: Which occurrence of a match to search for. If omitted, the default is 1.
  - **match_type**: A string that specifies how to perform matching. The meaning is as described for **REGEXP_LIKE()**.

  For additional information about how matching occurs, see the description for **REGEXP_LIKE()**.

  ```sql
  mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+');
  +----------------------------------------+
  | REGEXP_SUBSTR('abc def ghi', '[a-z]+') |
  +----------------------------------------+
  | abc                                    |
  +----------------------------------------+
  mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3);
  +----------------------------------------------+
  | REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3) |
  +----------------------------------------------+
  | ghi                                          |
  +----------------------------------------------+
  ```

Regular Expression Syntax

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the | alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

The following list covers some of the basic special characters and constructs that can be used in regular expressions. For information about the full regular expression syntax supported by the ICU library used to implement regular expression support, visit the [International Components for Unicode website](https://www.unicode.org/reports/tr36/).

- **^**

  Match the beginning of a string.

  ```sql
  mysql> SELECT REGEXP_LIKE('fo\nfo', '^fo$');    -> 0
  mysql> SELECT REGEXP_LIKE('fo\nfo', '^fo$');    -> 1
  ```

- **$**
Regular Expressions

Match the end of a string.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('fo\no', '^fo\no$');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('fo\no', '^fo$');</td>
<td>0</td>
</tr>
</tbody>
</table>

• .

Match any character (including carriage return and newline, although to match these in the middle of a string, the m (multiple line) match-control character or the (?m) within-pattern modifier must be given).

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('fofo', '^f.*$');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('fo\rnfo', '^f.*$');</td>
<td>0</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('fo\rnfo', '^f.*$', 'm');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('fo\rnfo', '(?m)^f.*$');</td>
<td>1</td>
</tr>
</tbody>
</table>

• a*

Match any sequence of zero or more a characters.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('Ban', '^Ba*n');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('Baaan', '^Ba*n');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('Bn', '^Ba*n');</td>
<td>1</td>
</tr>
</tbody>
</table>

• a+

Match any sequence of one or more a characters.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('Ban', '^Ba+n');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('Bn', '^Ba+n');</td>
<td>0</td>
</tr>
</tbody>
</table>

• a?

Match either zero or one a character.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('Bn', '^Ba?n');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('Ban', '^Ba?n');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('Baan', '^Ba?n');</td>
<td>0</td>
</tr>
</tbody>
</table>

• de|abc

Alternation; match either of the sequences de or abc.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('pi', 'pi</td>
<td>apa');</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('axe', 'pi</td>
<td>apa');</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('apa', 'pi</td>
<td>apa');</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('apa', '^pi</td>
<td>apa$');</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('pi', '^pi</td>
<td>apa$');</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('pix', '^pi</td>
<td>apa$');</td>
</tr>
</tbody>
</table>

• (abc)*

Match zero or more instances of the sequence abc.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT REGEXP_LIKE('pi', '^(pi)*$');</td>
<td>1</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('pip', '^(pi)*$');</td>
<td>0</td>
</tr>
<tr>
<td>SELECT REGEXP_LIKE('pipi', '^(pi)*$');</td>
<td>1</td>
</tr>
</tbody>
</table>
• \( \{1, \}, \{2,3\} \)

Repetition; \( \{n\} \) and \( \{m, n\} \) notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. \( m \) and \( n \) are integers.

• \( a^* \)

Can be written as \( a \{0,\} \).

• \( a^+ \)

Can be written as \( a \{1,\} \).

• \( a? \)

Can be written as \( a \{0,1\} \).

To be more precise, \( a \{n\} \) matches exactly \( n \) instances of \( a \). \( a \{n,\} \) matches \( n \) or more instances of \( a \). \( a \{m, n\} \) matches \( m \) through \( n \) instances of \( a \), inclusive. If both \( m \) and \( n \) are given, \( m \) must be less than or equal to \( n \).

```
mysql> SELECT REGEXP_LIKE('abcde', 'a\[bcd\]{2}e'); -> 0
mysql> SELECT REGEXP_LIKE('abcde', 'a\[bcd\]{3}e'); -> 1
mysql> SELECT REGEXP_LIKE('abcde', 'a\[bcd\]{1,10}e'); -> 1
```
Character Class  | Meaning
---|---
alnum | Alphanumeric characters
alpha | Alphabetic characters
blank | Whitespace characters
cntrl | Control characters
digit | Digit characters
graph | Graphic characters
lower | Lowercase alphabetic characters
print | Graphic or space characters
punct | Punctuation characters
space | Space, tab, newline, and carriage return
upper | Uppercase alphabetic characters
xdigit | Hexadecimal digit characters

```sql
mysql> SELECT REGEXP_LIKE('justalnums', '[:alnum:]'); -> 1
mysql> SELECT REGEXP_LIKE('!!', '[:alnum:]'); -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```sql
mysql> SELECT REGEXP_LIKE('1+2', '1+2'); -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\+2'); -> 1
```

**Regular Expression Resource Control**

REGEXP_LIKE() and similar functions use resources that can be controlled by setting system variables:

- The match engine uses memory for its internal stack. To control the maximum available memory for the stack in bytes, set the regexp_stack_limit system variable.

- The match engine operates in steps. To control the maximum number of steps performed by the engine (and thus indirectly the execution time), set the regexp_time_limit system variable. Because this limit is expressed as number of steps, it affects execution time only indirectly. Typically, it is on the order of milliseconds.

**Regular Expression Compatibility Considerations**

Prior to MySQL 8.0.4, MySQL used the Henry Spencer regular expression library to support regular expression operations, rather than International Components for Unicode (ICU). The following discussion describes differences between the Spencer and ICU libraries that may affect applications:

- With the Spencer library, the REGEXP and RLIKE operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.
ICU has full Unicode support and is multibyte safe. Its regular expression functions treat all strings as as UTF-16. You should keep in mind that positional indexes are based on 16-bit chunks and not on code points. This means that, when passed to such functions, characters using more than one chunk may produce unanticipated results, such as those shown here:

```sql
mysql> SELECT REGEXP_INSTR('??b', 'b');
+--------------------------+
| REGEXP_INSTR('??b', 'b') |
| 5                       |
+--------------------------+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('??bxxx', 'b', 4);
+--------------------------------+
| REGEXP_INSTR('??bxxx', 'b', 4) |
| 5                              |
+--------------------------------+
1 row in set (0.00 sec)
```

Characters within the Unicode Basic Multilingual Plane, which includes characters used by most modern languages, are safe in this regard:

```sql
mysql> SELECT REGEXP_INSTR('бж', 'b');
+----------------------------+
| REGEXP_INSTR('бж', 'b')   |
|                          3 |
+----------------------------+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('בע', 'b');
+----------------------------+
| REGEXP_INSTR('בע', 'b')   |
|                          3 |
+----------------------------+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('µå周çб', '周');
+------------------------------------+
| REGEXP_INSTR('µå周çб', '周')       |
|                                  3 |
+------------------------------------+
1 row in set (0.00 sec)
```

Emoji, such as the “sushi” character ⚠️ (U+1F363) used in the first two examples, are not included in the Basic Multilingual Plane, but rather in Unicode’s Supplementary Multilingual Plane. Another issue can arise with emoji and other 4-byte characters when `REGEXP_SUBSTR()` or a similar function begins searching in the middle of a character. Each of the two statements in the following example starts from the second 2-byte position in the first argument. The first statement works on a string consisting solely of 2-byte (BMP) characters. The second statement contains 4-byte characters which are incorrectly interpreted in the result because the first two bytes are stripped off and so the remainder of the character data is misaligned.

```sql
mysql> SELECT REGEXP_SUBSTR('周周周周', '.*', 2);
+------------------------------------+
| REGEXP_SUBSTR('周周周周', '.*', 2) |
|                                  3 |
+------------------------------------+
1 row in set (0.00 sec)
```
• For the \ operator, the Spencer library matches line-terminator characters (carriage return, newline) anywhere in string expressions, including in the middle. To match line terminator characters in the middle of strings with ICU, specify the m match-control character.

• The Spencer library supports word-beginning and word-end boundary markers ([[:<:]] and [[:>:]]) notation. ICU does not. For ICU, you can use \b to match word boundaries; double the backslash because MySQL interprets it as the escape character within strings.

• The Spencer library supports collating element bracket expressions ([.characters.]) notation. ICU does not.

• For repetition counts (\{n\} and \{m,n\} notation), the Spencer library has a maximum of 255. ICU has no such limit, although the maximum number of match engine steps can be limited by setting the regexp_time_limit system variable.

• ICU interprets parentheses as metacharacters. To specify a literal open parenthesis in a regular expression, it must be escaped:

```
mysql> SELECT REGEXP_LIKE('(', '\(');
ERROR 3692 (HY000): Mismatched parenthesis in regular expression.
```

```
mysql> SELECT REGEXP_LIKE('(', '\\(');
```

```
<table>
<thead>
<tr>
<th>REGEXP_LIKE('(', '\(')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>-------------------------</td>
</tr>
</tbody>
</table>
```

12.5.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, \texttt{UPPER(X)} returns a string with the same character string and collation as \texttt{X}. The same applies for \texttt{INSTR()}, \texttt{LCASE()}, \texttt{LOWER()}, \texttt{LTRIM()}, \texttt{MID()}, \texttt{REPEAT()}, \texttt{REPLACE()}, \texttt{REVERSE()}, \texttt{RIGHT()}, \texttt{RPAD()}, \texttt{RTRIM()}, \texttt{SOUNDEX()}, \texttt{SUBSTRING()}, \texttt{TRIM()}, \texttt{UCASE()}, and \texttt{UPPER()}.

\begin{note}
\textbf{The REPLACE()} function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.
\end{note}
If a string input or function result is a binary string, the string has the binary character set and collation. This can be checked by using the CHARSET() and COLLATION() functions, both of which return binary for a binary string argument:

```sql
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+---------------------+-----------------------+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
| binary              | binary                |
+---------------------+-----------------------+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit COLLATE Y occurs, use Y.
- If explicit COLLATE Y and COLLATE Z occur, raise an error.
- Otherwise, if all collations are Y, use Y.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is X. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”). This applies only to `BIN_TO_UUID()`, `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

An exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `BIN_TO_UUID()`, `CONV()`, or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the CHARSET() or COLLATION() function to find out:

```sql
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+----------------+-----------------+-------------------+
| USER()         | CHARSET(USER()) | COLLATION(USER()) |
| test@localhost | utf8            | utf8_general_ci   |
+----------------+-----------------+-------------------+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+--------------------------+----------------------------+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
| binary                   | binary                     |
+--------------------------+----------------------------+
```

<tr>
<td>+</td>
<td>Addition operator</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication operator</td>
</tr>
<tr>
<td>−</td>
<td>Change the sign of the argument</td>
</tr>
</tbody>
</table>

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of −, +, and *, the result is calculated with BIGINT (64-bit) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the NO_UNSIGNED_SUBTRACTION SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a +, −, /, *, % is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with /, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the div_precision_increment system variable (which is 4 by default). For example, the result of the expression 5.05 / 0.014 has a scale of six decimal places (360.714286).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, (14620 / 9432456) / (24250 / 9432456), resolves first to (0.0014) / (0.0026), with the final result having 8 decimal places (0.60288653).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See Section 12.10, “Cast Functions and Operators”.

For information about handling of overflow in numeric expression evaluation, see Section 11.2.6, "Out-of-Range and Overflow Handling".

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use DATE_ADD () ; see Section 12.7, "Date and Time Functions".

- +
  Addition:

```sql
mysql> SELECT 3+5;
-> 8
```

- −
  Subtraction:

```sql
mysql> SELECT 3-5;
-> -2
```
Arithmetic Operators

• \(-\)

Unary minus. This operator changes the sign of the operand.

www.mysql> SELECT - 2;
-> -2

Note

If this operator is used with a \texttt{BIGINT}, the return value is also a \texttt{BIGINT}. This means that you should avoid using \(-\) on integers that may have the value of $-2^{63}$.

• \(*\)

Multiplication:

www.mysql> SELECT 3*5;
-> 15
www.mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
www.mysql> SELECT 18014398509481984*18014398509481984;
-> out-of-range error

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of \texttt{BIGINT} calculations. (See Section 11.2, "Numeric Types").

• \(/\)

Division:

www.mysql> SELECT 3/5;
-> 0.60

Division by zero produces a \texttt{NULL} result:

www.mysql> SELECT 102/(1-1);
-> NULL

A division is calculated with \texttt{BIGINT} arithmetic only if performed in a context where its result is converted to an integer.

• \texttt{DIV}\n
Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to \texttt{DECIMAL} and divided using \texttt{DECIMAL} arithmetic before converting the result to \texttt{BIGINT}. If the result exceeds \texttt{BIGINT} range, an error occurs.

www.mysql> SELECT 5 \texttt{DIV} 2, -5 \texttt{DIV} 2, 5 \texttt{DIV} -2, -5 \texttt{DIV} -2;
-> 2, -2, -2, 2

• \texttt{N \% M}, \texttt{N \textsc{mod} M}\n
Modulo operation. Returns the remainder of \texttt{N} divided by \texttt{M}. For more information, see the description for the \texttt{MOD()} function in Section 12.6.2, “Mathematical Functions”.

</table>

All mathematical functions return **NULL** in the event of an error.

- **ABS(X)**
  
  Returns the absolute value of **X**.

```sql
mysql> SELECT ABS(2);
```
This function is safe to use with `BIGINT` values.

- **ACOS (X)**

  Returns the arc cosine of \( X \), that is, the value whose cosine is \( X \). Returns `NULL` if \( X \) is not in the range from \(-1\) to \(1\).

```
mysql> SELECT ACOS(1);   
-> 0 

mysql> SELECT ACOS(1.0001);   
-> NULL 

mysql> SELECT ACOS(0);   
-> 1.5707963267949
```

- **ASIN (X)**

  Returns the arc sine of \( X \), that is, the value whose sine is \( X \). Returns `NULL` if \( X \) is not in the range from \(-1\) to \(1\).

```
mysql> SELECT ASIN(0.2);   
-> 0.20135792079033 

mysql> SELECT ASIN('foo');   
+-------------+ 
| ASIN('foo') | 
+-------------+   
| 0 | 
+-------------+   
1 row in set, 1 warning (0.00 sec) 

mysql> SHOW WARNINGS;   
+---------+------+-----------------------------------------+ 
| Level   | Code | Message                                 | 
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' | 
+---------+------+-----------------------------------------+ 
```

- **ATAN (X)**

  Returns the arc tangent of \( X \), that is, the value whose tangent is \( X \).

```
mysql> SELECT ATAN(2);   
-> 1.1071487177941 

mysql> SELECT ATAN(-2);   
-> -1.1071487177941 

mysql> SELECT ATAN(0,2);   
-> -0.78539816339745 

mysql> SELECT ATAN2(PI(),0);   
-> 1.5707963267949
```

- **ATAN2 (Y, X)**

  Returns the arc tangent of the two variables \( X \) and \( Y \). It is similar to calculating the arc tangent of \( Y / X \), except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN2(-2,2);   
-> -0.78539816339745 

mysql> SELECT ATAN2(PI(),0);   
-> 1.5707963267949 
```

- **CEIL (X)**
CEIL() is a synonym for CEILING().

- **CEILING(X)**

Returns the smallest integer value not less than X.

```sql
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **CONV(N, from_base, to_base)**

Converts numbers between different number bases. Returns a string representation of the number N, converted from base from_base to base to_base. Returns NULL if any argument is NULL. The argument N is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If from_base is a negative number, N is regarded as a signed number. Otherwise, N is treated as unsigned. CONV() works with 64-bit precision.

```sql
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
-> '172'
mysql> SELECT CONV(-17,10,-18);
-> '-H'
mysql> SELECT CONV(10+'10'+X'0a',10,10);
-> '40'
```

- **COS(X)**

Returns the cosine of X, where X is given in radians.

```sql
mysql> SELECT COS(PI());
-> -1
```

- **COT(X)**

Returns the cotangent of X.

```sql
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> out-of-range error
```

- **CRC32(expr)**

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is NULL if the argument is NULL. The argument is expected to be a string and (if possible) is treated as one if it is not.

```sql
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```
Mathematical Functions

• **DEGREES**(X)

  Returns the argument X, converted from radians to degrees.

  ```
  mysql> SELECT DEGREES(PI());
  -> 180
  mysql> SELECT DEGREES(PI() / 2);
  -> 90
  ```

• **EXP**(X)

  Returns the value of e (the base of natural logarithms) raised to the power of X. The inverse of this function is **LOG** (using a single argument only) or **LN**.

  ```
  mysql> SELECT EXP(2);
  -> 7.3890560989307
  mysql> SELECT EXP(-2);
  -> 0.13533528323661
  mysql> SELECT EXP(0);
  -> 1
  ```

• **FLOOR**(X)

  Returns the largest integer value not greater than X.

  ```
  mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
  -> 1, -2
  ```

  For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

• **FORMAT**(X, D)

  Formats the number X to a format like '###,###,###.##', rounded to D decimal places, and returns the result as a string. For details, see Section 12.5, “String Functions”.

• **HEX**(N_or_S)

  This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in Section 12.5, “String Functions”, for details.

• **LN**(X)

  Returns the natural logarithm of X; that is, the base-e logarithm of X. If X is less than or equal to 0.0E0, the function returns **NULL** and a warning “Invalid argument for logarithm” is reported.

  ```
  mysql> SELECT LN(2);
  -> 0.69314718055995
  mysql> SELECT LN(-2);
  -> NULL
  ```

  This function is synonymous with **LOG**(X). The inverse of this function is the **EXP**( ) function.

• **LOG**(X), **LOG**(B, X)

  If called with one parameter, this function returns the natural logarithm of X. If X is less than or equal to 0.0E0, the function returns **NULL** and a warning “Invalid argument for logarithm” is reported.
Mathematical Functions

The inverse of this function (when called with a single argument) is the \texttt{EXP()} function.

\begin{verbatim}
mysql> SELECT LOG(2);
-> 0.69314718055995
mysql> SELECT LOG(-2);
-> NULL
\end{verbatim}

If called with two parameters, this function returns the logarithm of \(X\) to the base \(B\). If \(X\) is less than or equal to 0, or if \(B\) is less than or equal to 1, then \texttt{NULL} is returned.

\begin{verbatim}
mysql> SELECT LOG(2,65536);
-> 16
mysql> SELECT LOG(10,100);
-> 2
mysql> SELECT LOG(1,100);
-> NULL
\end{verbatim}

\texttt{LOG(B, X)} is equivalent to \texttt{LOG(X) / LOG(B)}.

- \texttt{LOG2(X)}

Returns the base-2 logarithm of \(X\). If \(X\) is less than or equal to 0.0E0, the function returns \texttt{NULL} and a warning "Invalid argument for logarithm" is reported.

\begin{verbatim}
mysql> SELECT LOG2(65536);
-> 16
mysql> SELECT LOG2(-100);
-> NULL
\end{verbatim}

\texttt{LOG2()} is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression \texttt{LOG(X) / LOG(2)}.

- \texttt{LOG10(X)}

Returns the base-10 logarithm of \(X\). If \(X\) is less than or equal to 0.0E0, the function returns \texttt{NULL} and a warning "Invalid argument for logarithm" is reported.

\begin{verbatim}
mysql> SELECT LOG10(2);
-> 0.30102999566398
mysql> SELECT LOG10(100);
-> 2
mysql> SELECT LOG10(-100);
-> NULL
\end{verbatim}

\texttt{LOG10(X)} is equivalent to \texttt{LOG(10, X)}.

- \texttt{MOD(N, M), N \% M, N MOD M}

Modulo operation. Returns the remainder of \(N\) divided by \(M\).

\begin{verbatim}
mysql> SELECT MOD(234, 10);
-> 4
mysql> SELECT 253 \% 7;
-> 1
mysql> SELECT MOD(29,9);
-> 2
mysql> SELECT 29 MOD 9;
\end{verbatim}
This function is safe to use with BIGINT values.

MOD() also works on values that have a fractional part and returns the exact remainder after division:

```sql
mysql> SELECT MOD(34.5,3);
-> 1.5
```

MOD(N, 0) returns NULL.

• PI()

Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```sql
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.000000000000000000;
-> 3.141592653589793116
```

• POW(X, Y)

Returns the value of X raised to the power of Y.

```sql
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

• POWER(X, Y)

This is a synonym for POW().

• RADIANS(X)

Returns the argument X, converted from degrees to radians. (Note that π radians equals 180 degrees.)

```sql
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

• RAND([N])

Returns a random floating-point value v in the range 0 <= v < 1.0. To obtain a random integer R in the range i <= R < j, use the expression FLOOR(i + RAND() * (j - i)). For example, to obtain a random integer in the range the range 7 <= R < 12, use the following statement:

```sql
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument N is specified, it is used as the seed value:

• With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.

• With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of RAND().
One implication of this behavior is that for equal argument values, \( \text{RAND}(N) \) returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by \( \text{RAND}(3) \) is the same both places it occurs.

```sql
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT i, RAND() FROM t;
+----+------------------+
<table>
<thead>
<tr>
<th>i</th>
<th>RAND()</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.61914388706828</td>

3 rows in set (0.01 sec)
```

\( \text{RAND()} \) in a \texttt{WHERE} clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, \( \text{RAND()} \) is not a constant value and cannot be used for index optimizations. For more information, see Section 8.2.1.18, "Function Call Optimization".

Use of a column with \( \text{RAND()} \) values in an \texttt{ORDER BY} or \texttt{GROUP BY} clause may yield unexpected results because for either clause a \( \text{RAND()} \) expression can be evaluated multiple times for the same row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:
To select a random sample from a set of rows, combine ORDER BY RAND() with LIMIT:

```sql
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine ORDER BY RAND() with LIMIT:

```sql
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

RAND() is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #49222)

- **ROUND (X), ROUND (X, D)**

Rounds the argument `X` to `D` decimal places. The rounding algorithm depends on the data type of `X`. `D` defaults to 0 if not specified. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

```
mysql> SELECT ROUND(-1.23);
   
   -> -1
```

```
mysql> SELECT ROUND(-1.58);
   
   -> -2
```

```
mysql> SELECT ROUND(1.58);
   
   -> 2
```

```
mysql> SELECT ROUND(1.298, 1);
   
   -> 1.3
```

```
mysql> SELECT ROUND(1.298, 0);
   
   -> 1
```

```
mysql> SELECT ROUND(23.298, -1);
   
   -> 20
```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);

+------------------+--------------+
| ROUND(150.000,2) | ROUND(150,2) |
|------------------+--------------|
| 150.00           | 150          |
+------------------+--------------+
```

**ROUND()** uses the following rules depending on the type of the first argument:

- For exact-value numbers, **ROUND()** uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

- For approximate-value numbers, the result depends on the C library. On many systems, this means that **ROUND()** uses the “round to nearest even” rule: A value with a fractional part exactly halfway between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);

+------------------+--------------+
| ROUND(2.5)       | ROUND(25E-1) |
|------------------+--------------|
| 2                | 0.0          |
+------------------+--------------+
```
### Mathematical Functions

<table>
<thead>
<tr>
<th>ROUND(2.5)</th>
<th>ROUND(2.5E-1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

For more information, see Section 12.25, “Precision Math”.

• **SIGN**(*X*)

Returns the sign of the argument as -1, 0, or 1, depending on whether *X* is negative, zero, or positive.

```sql
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

• **SIN**(*X*)

Returns the sine of *X*, where *X* is given in radians.

```sql
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

• **SQRT**(*X*)

Returns the square root of a nonnegative number *X*.

```sql
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

• **TAN**(*X*)

Returns the tangent of *X*, where *X* is given in radians.

```sql
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

• **TRUNCATE**(*X*, *D*)

Returns the number *X*, truncated to *D* decimal places. If *D* is 0, the result has no decimal point or fractional part. *D* can be negative to cause *D* digits left of the decimal point of the value *X* to become zero.

```sql
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
```
All numbers are rounded toward zero.

### 12.7 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See Section 11.3, “Date and Time Types”, for a description of the range of values each date and time type has and the valid formats in which values may be specified.

#### Table 12.13 Date and Time Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDDATE()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>ADDTIME()</td>
<td>Add time</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one time zone to another</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime expression</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
<tr>
<td>EXTRACT()</td>
<td>Extract part of a date</td>
</tr>
<tr>
<td>FROM_DAYS()</td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td>FROM_UNIXTIME()</td>
<td>Format Unix timestamp as a date</td>
</tr>
<tr>
<td>GET_FORMAT()</td>
<td>Return a date format string</td>
</tr>
<tr>
<td>HOUR()</td>
<td>Extract the hour</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td>LOCALTIME(), LOCALTIME</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>LOCALTIMESTAMP, LOCALTIMESTAMP</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MADEDATE()</td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td>MAKETIME()</td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>PERIOD_ADD()</td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td>PERIOD_DIFF()</td>
<td>Return the number of months between periods</td>
</tr>
<tr>
<td>QUARTER()</td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td>SEC_TO_TIME()</td>
<td>Converts seconds to ‘HH:MM:SS’ format</td>
</tr>
<tr>
<td>SECOND()</td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td>STR_TO_DATE()</td>
<td>Convert a string to a date</td>
</tr>
<tr>
<td>SUBDATE()</td>
<td>Synonym for DATE_SUB() when invoked with three arguments</td>
</tr>
<tr>
<td>SUBTIME()</td>
<td>Subtract times</td>
</tr>
<tr>
<td>SYSDATE()</td>
<td>Return the time at which the function executes</td>
</tr>
<tr>
<td>TIME()</td>
<td>Extract the time portion of the expression passed</td>
</tr>
<tr>
<td>TIME_FORMAT()</td>
<td>Format as time</td>
</tr>
<tr>
<td>TIME_TO_SEC()</td>
<td>Return the argument converted to seconds</td>
</tr>
<tr>
<td>TIMEDIFF()</td>
<td>Subtract time</td>
</tr>
<tr>
<td>TIMESTAMP()</td>
<td>With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments</td>
</tr>
<tr>
<td>TIMESTAMPADD()</td>
<td>Add an interval to a datetime expression</td>
</tr>
<tr>
<td>TIMESTAMPDIFF()</td>
<td>Subtract an interval from a datetime expression</td>
</tr>
<tr>
<td>TO_DAYS()</td>
<td>Return the date argument converted to days</td>
</tr>
<tr>
<td>TO_SECONDS()</td>
<td>Return the date or datetime argument converted to seconds since Year 0</td>
</tr>
<tr>
<td>UNIX_TIMESTAMP()</td>
<td>Return a Unix timestamp</td>
</tr>
<tr>
<td>UTC_DATE()</td>
<td>Return the current UTC date</td>
</tr>
<tr>
<td>UTC_TIME()</td>
<td>Return the current UTC time</td>
</tr>
<tr>
<td>UTC_TIMESTAMP()</td>
<td>Return the current UTC date and time</td>
</tr>
<tr>
<td>WEEK()</td>
<td>Return the week number</td>
</tr>
<tr>
<td>WEEKDAY()</td>
<td>Return the weekday index</td>
</tr>
<tr>
<td>WEEKOFYEAR()</td>
<td>Return the calendar week of the date (1-53)</td>
</tr>
<tr>
<td>YEAR()</td>
<td>Return the year</td>
</tr>
<tr>
<td>YEARWEEK()</td>
<td>Return the year and week</td>
</tr>
</tbody>
</table>

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:
Date and Time Functions

```
mysql> SELECT something FROM tbl_name
-> WHERE DATE_SUB(CURDATE(), INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE(), CURTIME(), UTC_DATE(), UTC_TIME(), UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP(), CURRENT_TIME(), CURRENT_DATE(), and FROM_UNIXTIME()` functions return values in the connection's current time zone, which is available as the value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the current time zone. See Section 5.1.13, “MySQL Server Time Zone Support”.

Some date functions can be used with “zero” dates or incomplete dates such as '2001-11-00', whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
-> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL
```

Several functions are more strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero. These functions are affected: `CONVERT_TZ(), DATE_ADD(), DATE_SUB(), DAYOFYEAR(), LAST_DAY()` (permits a day part of zero), `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- `ADDDATE(date, INTERVAL expr unit), ADDDATE(expr, days)`

  When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see Temporal Intervals.

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`. 

Date and Time Functions

mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'

- **ADDTIME(expr1, expr2)**

ADDTIME() adds expr2 to expr1 and returns the result. expr1 is a time or datetime expression, and expr2 is a time expression.

mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'

mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'

- **CONVERT_TZ(dt, from_tz, to_tz)**

CONVERT_TZ() converts a datetime value dt from the time zone given by from_tz to the time zone given by to_tz and returns the resulting value. Time zones are specified as described in Section 5.1.13, "MySQL Server Time Zone Support". This function returns NULL if the arguments are invalid.

If the value falls out of the supported range of the TIMESTAMP type when converted from from_tz to UTC, no conversion occurs. The TIMESTAMP range is described in Section 11.1.2, "Date and Time Type Overview".

mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
-> '2004-01-01 13:00:00'

mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
-> '2004-01-01 22:00:00'

Note

To use named time zones such as 'MET' or 'Europe/Moscow', the time zone tables must be properly set up. See Section 5.1.13, "MySQL Server Time Zone Support", for instructions.

- **CURDATE()**

Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

mysql> SELECT CURDATE();
-> '2008-06-13'

mysql> SELECT CURDATE() + 0;
-> 20080613

- **CURRENT_DATE, CURRENT_DATE()**

CURRENT_DATE and CURRENT_DATE() are synonyms for CURDATE().

- **CURRENT_TIME, CURRENT_TIME([fsp])**

CURRENT_TIME and CURRENT_TIME() are synonyms for CURTIME().

- **CURRENT_TIMESTAMP, CURRENT_TIMESTAMP([fsp])**

CURRENT_TIMESTAMP and CURRENT_TIMESTAMP() are synonyms for NOW().

- **CURTIME([fsp])**
Returns the current time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

If the fsp argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- **DATE(expr)**

  Extracts the date part of the date or datetime expression expr.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- **DATEDIFF(expr1, expr2)**

  DATEDIFF() returns expr1 − expr2 expressed as a value in days from one date to the other. expr1 and expr2 are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- **DATE_ADD(date, INTERVAL expr unit), DATE_SUB(date, INTERVAL expr unit)**

  These functions perform date arithmetic. The date argument specifies the starting date or datetime value. expr is an expression specifying the interval value to be added or subtracted from the starting date. expr is evaluated as a string; it may start with a − for negative intervals. unit is a keyword indicating the units in which the expression should be interpreted.

  For more information about temporal interval syntax, including a full list of unit specifiers, the expected form of the expr argument for each unit value, and rules for operand interpretation in temporal arithmetic, see Temporal Intervals.

  The return value depends on the arguments:

  - **DATE** if the date argument is a DATE value and your calculations involve only YEAR, MONTH, and DAY parts (that is, no time parts).

  - **DATETIME** if the first argument is a DATETIME (or TIMESTAMP) value, or if the first argument is a DATE and the unit value uses HOURS, MINUTES, or SECONDS.

  - String otherwise.

  To ensure that the result is DATETIME, you can use CAST() to convert the first argument to DATETIME.

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
```
### Date and Time Functions

- `mysql>` `SELECT DATE_ADD('2020-12-31 23:59:59',` `INTERVAL 1 SECOND);` `-> '2021-01-01 00:00:00'
- `mysql>` `SELECT DATE_ADD('2100-12-31 23:59:59',` `INTERVAL '1:1' MINUTE_SECOND);` `-> '2101-01-01 00:01:00'
- `mysql>` `SELECT DATE_SUB('2025-01-01 00:00:00',` `INTERVAL '1 1:1:1' DAY_SECOND);` `-> '1999-12-30 14:00:00'
- `mysql>` `SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);` `-> '1997-12-02'
- `mysql>` `SELECT DATE_ADD('1992-12-31 23:59:59.000002',` `INTERVAL '1.999999' SECOND_MICROSECOND);` `-> '1993-01-01 00:00:01.000001'

- **DATE_FORMAT**(date, format)

  Formats the *date* value according to the *format* string.

  The following specifiers may be used in the *format* string. The `%` character is required before format specifier characters.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday name (Sun..Sat)</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month name (Jan..Dec)</td>
</tr>
<tr>
<td>%c</td>
<td>Month, numeric (0..12)</td>
</tr>
<tr>
<td>%D</td>
<td>Day of the month with English suffix (0th, 1st, 2nd, 3rd, …)</td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month, numeric (00..31)</td>
</tr>
<tr>
<td>%e</td>
<td>Day of the month, numeric (0..31)</td>
</tr>
<tr>
<td>%f</td>
<td>Microseconds (000000..999999)</td>
</tr>
<tr>
<td>%H</td>
<td>Hour (00..23)</td>
</tr>
<tr>
<td>%h</td>
<td>Hour (01..12)</td>
</tr>
<tr>
<td>%I</td>
<td>Hour (01..12)</td>
</tr>
<tr>
<td>%i</td>
<td>Minutes, numeric (00..59)</td>
</tr>
<tr>
<td>%j</td>
<td>Day of year (001..366)</td>
</tr>
<tr>
<td>%k</td>
<td>Hour (0..23)</td>
</tr>
<tr>
<td>%l</td>
<td>Hour (1..12)</td>
</tr>
<tr>
<td>%M</td>
<td>Month name (January..December)</td>
</tr>
<tr>
<td>%m</td>
<td>Month, numeric (00..12)</td>
</tr>
<tr>
<td>%p</td>
<td>AM or PM</td>
</tr>
<tr>
<td>%r</td>
<td>Time, 12-hour (hh:mm:ss followed by AM or PM)</td>

<td>x, for any “x” not listed above</td>
</tr>
</tbody>
</table>

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as ‘2014-00-00’.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 10.15, “MySQL Server Locale Support”).

For the %U, %u, %V, and %v specifiers, see the description of the WEEK() function for information about the mode values. The mode affects how week numbering occurs.

`DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```sql
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %I %i %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%x %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date,INTERVAL expr unit)`

See the description for `DATE_ADD()`.
• **DAY(date)**

`DAY()` is a synonym for `DAYOFMONTH()`.

• **DAYNAME(date)**

Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.15, “MySQL Server Locale Support”).

```sql
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

• **DAYOFMONTH(date)**

Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

```sql
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

• **DAYOFWEEK(date)**

Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```sql
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

• **DAYOFYEAR(date)**

Returns the day of the year for `date`, in the range 1 to 366.

```sql
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

• **EXTRACT(unit FROM date)**

The `EXTRACT()` function uses the same kinds of `unit` specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic. For information on the `unit` argument, see Temporal Intervals.

```sql
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
-> 123
```

• **FROM_DAYS(N)**

Given a day number `N`, returns a `DATE` value.

```sql
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```
Date and Time Functions

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 12.8, “What Calendar Is Used By MySQL?”.

- `FROM_UNIXTIME(unix_timestamp), FROM_UNIXTIME(unix_timestamp, format)`

Returns a representation of the `unix_timestamp` argument as a value in 'YYYY-MM-DD HH:MM:SS' or 'YYYYMMDDHHMMSS' format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. `unix_timestamp` is an internal timestamp value such as is produced by the `UNIX_TIMESTAMP()` function.

If `format` is given, the result is formatted according to the `format` string, which is used the same way as listed in the entry for the `DATE_FORMAT()` function.

mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(), '%%Y %%D %%M  %%h:%%i:%%s  %%x');
-> '2015 13th November 10:08:01 2015'

**Note**

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

<table>
<thead>
<tr>
<th>Function Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_FORMAT(DATE, 'USA')</td>
<td>'%m.%d.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE, 'JIS')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE, 'ISO')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE, 'EUR')</td>
<td>'%d.%m.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE, 'INTERNAL')</td>
<td>'%Y%m%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME, 'USA')</td>
<td>'%Y-%m-%d %H.%i.%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME, 'JIS')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME, 'ISO')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME, 'EUR')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>

<tr>
<td>GET_FORMAT(DATETIME, 'INTERNAL')</td>
<td>'%Y%m%d%H%i%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME, 'USA')</td>
<td>'%h:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME, 'JIS')</td>
<td>'%H:%i:%s'</td>
</tr>
</tbody>
</table>
Date and Time Functions

<table>
<thead>
<tr>
<th>Function Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_FORMAT(TIME, 'ISO')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME, 'EUR')</td>
<td>'%H.%i.%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME, 'INTERNAL')</td>
<td>'%H%i%s'</td>
</tr>
</tbody>
</table>

**TIMESTAMP** can also be used as the first argument to GET_FORMAT(), in which case the function returns the same values as for DATETIME.

```sql
mysql> SELECT DATE_FORMAT('2003-10-03', GET_FORMAT(DATE, 'EUR'));
-> '03.10.2003'
```

```sql
mysql> SELECT STR_TO_DATE('10.31.2003', GET_FORMAT(DATE, 'USA'));
-> '2003-10-31'
```

• **HOUR(time)**

  Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of TIME values actually is much larger, so HOUR can return values greater than 23.

```sql
mysql> SELECT HOUR('10:05:03');
-> 10
```

```sql
mysql> SELECT HOUR('272:59:59');
-> 272
```

• **LAST_DAY(date)**

  Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid.

```sql
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
```

```sql
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
```

```sql
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
```

```sql
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

• **LOCALTIME, LOCALTIME([fsp])**

  **LOCALTIME** and **LOCALTIME()** are synonyms for **NOW()**.

• **LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])**

  **LOCALTIMESTAMP** and **LOCALTIMESTAMP([fsp])** are synonyms for **NOW()**.

• **MAKEDATE(year, dayofyear)**

  Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is NULL.

```sql
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
```

```sql
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
```

```sql
mysql> SELECT MAKEDATE(2011,0);
-> NULL
```
• **MAKETIME(hour, minute, second)**

Returns a time value calculated from the `hour`, `minute`, and `second` arguments.

The `second` argument can have a fractional part.

```sql
mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'
```

• **MICROSECOND(expr)**

Returns the microseconds from the time or datetime expression `expr` as a number in the range from 0 to 999999.

```sql
mysql> SELECT MICROSECOND('12:00:00.123456');
-> 123456
mysql> SELECT MICROSECOND('2019-12-31 23:59:59.000010');
-> 10
```

• **MINUTE(time)**

Returns the minute for `time`, in the range 0 to 59.

```sql
mysql> SELECT MINUTE('2008-02-03 10:05:03');
-> 5
```

• **MONTH(date)**

Returns the month for `date`, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```sql
mysql> SELECT MONTH('2008-02-03');
-> 2
```

• **MONTHNAME(date)**

Returns the full name of the month for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.15, "MySQL Server Locale Support").

```sql
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

• **NOW([fsp])**

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```sql
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```
**Date and Time Functions**

**NOW()** returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, **NOW()** returns the time at which the function or triggering statement began to execute.) This differs from the behavior for **SYSDATE()**, which returns the exact time at which it executes.

```sql
mysql> SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
```

```sql
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
```

In addition, the **SET TIMESTAMP** statement affects the value returned by **NOW()** but not by **SYSDATE()**. This means that timestamp settings in the binary log have no effect on invocations of **SYSDATE()**. Setting the timestamp to a nonzero value causes each subsequent invocation of **NOW()** to return that value. Setting the timestamp to zero cancels this effect so that **NOW()** once again returns the current date and time.

See the description for **SYSDATE()** for additional information about the differences between the two functions.

- **PERIOD_ADD**(P, N)
  Adds N months to period P (in the format **YYMM** or **YYYYMM**). Returns a value in the format **YYYYMM**. Note that the period argument P is not a date value.

```sql
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- **PERIOD_DIFF**(P1, P2)
  Returns the number of months between periods P1 and P2. P1 and P2 should be in the format **YYMM** or **YYYYMM**. Note that the period arguments P1 and P2 are not date values.

```sql
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- **QUARTER**(date)
  Returns the quarter of the year for date, in the range 1 to 4.

```sql
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- **SECOND**(time)
  Returns the second for time, in the range 0 to 59.

```sql
mysql> SELECT SECOND('10:05:03');
```
Date and Time Functions

- **SEC_TO_TIME(seconds)**

  Returns the `seconds` argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

  ```
  mysql> SELECT SEC_TO_TIME(2378);
  -> '00:39:38'
  mysql> SELECT SEC_TO_TIME(2378) + 0;
  -> 3938
  ```

- **STR_TO_DATE(str, format)**

  This is the inverse of the `DATE_FORMAT()` function. It takes a string `str` and a format string `format`. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from `str` is illegal, `STR_TO_DATE()` returns NULL and produces a warning.

  The server scans `str` attempting to match `format` to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in `format` must match literally in `str`. Format specifiers in `format` must match a date or time part in `str`. For the specifiers that can be used in `format`, see the `DATE_FORMAT()` function description.

  ```
  mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
  -> '2013-05-01'
  mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
  -> '2013-05-01'
  ```

  Scanning starts at the beginning of `str` and fails if `format` is found not to match. Extra characters at the end of `str` are ignored.

  ```
  mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
  -> '09:30:17'
  mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
  -> NULL
  mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
  -> '09:30:17'
  ```

  Unspecified date or time parts have a value of 0, so incompletely specified values in `str` produce a result with some or all parts set to 0:

  ```
  mysql> SELECT STR_TO_DATE('abc','abc');
  -> '0000-00-00'
  mysql> SELECT STR_TO_DATE('9','%m');
  -> '0000-09-00'
  mysql> SELECT STR_TO_DATE('9','%s');
  -> '00:00:09'
  ```

  Range checking on the parts of date values is as described in Section 11.3.1, “The DATE, DATETIME, and TIMESTAMP Types”. This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.
If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled, zero dates or part of dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```sql
mysql> SET sql_mode = '';

mysql> SELECT STR_TO_DATE('15:35:00', '%H:%i:%s');
+-------------------------------------+
<table>
<thead>
<tr>
<th>STR_TO_DATE('15:35:00', '%H:%i:%s')</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:35:00</td>
</tr>
</tbody>
</table>
+-------------------------------------+

mysql> SET sql_mode = 'NO_ZERO_IN_DATE';

mysql> SELECT STR_TO_DATE('15:35:00', '%h:%i:%s');
+-------------------------------------+
<table>
<thead>
<tr>
<th>STR_TO_DATE('15:35:00', '%h:%i:%s')</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
</tr>
</tbody>
</table>
+-------------------------------------+

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 1411
Message: Incorrect datetime value: '15:35:00' for function str_to_date
```

**Note**

You cannot use format "%X%V" to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```sql
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

* `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```sql
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'

mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```sql
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

* `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```sql
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
```
Date and Time Functions

- **SYSDATE([fsp])**

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

**SYSDATE()** returns the time at which it executes. This differs from the behavior for **NOW()**, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, **NOW()** returns the time at which the function or triggering statement began to execute.)

```sql
mysql> SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
```

In addition, the **SET TIMESTAMP** statement affects the value returned by **NOW()** but not by **SYSDATE()**. This means that timestamp settings in the binary log have no effect on invocations of **SYSDATE()**.

Because **SYSDATE()** can return different values even within the same statement, and is not affected by **SET_TIMESTAMP**, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the **--sysdate-is-now** option to cause **SYSDATE()** to be an alias for **NOW()**. This works if the option is used on both the master and the slave.

The nondeterministic nature of **SYSDATE()** also means that indexes cannot be used for evaluating expressions that refer to it.

- **TIME(expr)**

Extracts the time part of the time or datetime expression *expr* and returns it as a string.

This function is unsafe for statement-based replication. A warning is logged if you use this function when **binlog_format** is set to **STATEMENT**.

```sql
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- **TIMEDIFF(expr1, expr2)**

**TIMEDIFF()** returns *expr1* − *expr2* expressed as a time value. *expr1* and *expr2* are time or date-and-time expressions, but both must be of the same type.
The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```sql
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- **TIMESTAMP (expr), TIMESTAMP (expr1, expr2)**

  With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

  ```sql
  mysql> SELECT TIMESTAMP('2003-12-31');
  -> '2003-12-31 00:00:00'
  mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
  -> '2004-01-01 00:00:00'
  ```

- **TIMESTAMPADD(unit, interval, datetime_expr)**

  Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: MICROSECOND (microseconds), SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

  The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI`. For example, DAY and SQL_TSI_DAY both are legal.

  ```sql
  mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
  -> '2003-01-02 00:01:00'
  mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
  -> '2003-01-09'
  ```

- **TIMESTAMPDIFF(unit, datetime_expr1, datetime_expr2)**

  Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the `unit` argument. The legal values for `unit` are the same as those listed in the description of the `TIMESTAMPADD()` function.

  ```sql
  mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
  -> 3
  mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
  -> -1
  mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
  -> 128885
  ```

**Note**

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.
Date and Time Functions

• **TIME_FORMAT(time, format)**

This is used like the `DATE_FORMAT()` function, but the `format` string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or 0.

If the `time` value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

• **TIME_TO_SEC(time)**

Returns the `time` argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

• **TO_DAYS(date)**

Given a date `date`, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.8, “What Calendar Is Used By MySQL?”, for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.3, “Date and Time Types”. For example, '2008-10-07' and '08-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_DAYS()` returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----------------------+
| to_days('0000-00-00') |
+-----------------------+
| NULL |
+-----------------------+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
|---------+------|----------------------------------------|
+---------+------|----------------------------------------+
```

1892
Date and Time Functions

- **TO_DAYS**
  - This function returns the number of days since the year 0. It is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.8, “What Calendar Is Used By MySQL?”, for details.

- **TO_SECONDS**
  - This function returns the number of seconds since the year 0. It is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.8, “What Calendar Is Used By MySQL?”, for details.

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', TO_SECONDS() returns the values shown here:

```
SELECT TO_SECONDS('0000-00-00');
+--------------------------+
| TO_SECONDS('0000-00-00') |
|--------------------------+
| NULL                    |
+--------------------------+
SELECT TO_SECONDS('0000-01-01');
+--------------------------+
| TO_SECONDS('0000-01-01') |
+--------------------------+
```

This is true whether or not the ALLOW_INVALID_DATES SQL server mode is enabled.

- **TO_SECONDS(expr)**
  - Given a date or datetime expr, returns the number of seconds since the year 0. If expr is not a valid date or datetime value, returns NULL.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS(NOW());
-> 63426721458
```
This is true whether or not the ALLOW_INVALID_DATES SQL server mode is enabled.

- **UNIX_TIMESTAMP()**, **UNIX_TIMESTAMP**(date)

  If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC). The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or **DECIMAL** if an argument is given that includes a fractional seconds part.

  If **UNIX_TIMESTAMP()** is called with a date argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. The date argument may be a DATE, DATETIME, or TIMESTAMP string, or a number in YYMMDD, YYMMDHHMMSS, YYYYMMDD, or YYYYMMDDHHMMSS format. If the argument includes a time part, it may optionally include a fractional seconds part. The server interprets date as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in Section 5.1.13, “MySQL Server Time Zone Support”.

```
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012
```

When **UNIX_TIMESTAMP()** is used on a TIMESTAMP column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to **UNIX_TIMESTAMP()**, it returns 0. The valid range of values is the same as for the TIMESTAMP data type: '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC.

If you use **UNIX_TIMESTAMP()** and **FROM_UNIXTIME()** to convert between TIMESTAMP values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two **UNIX_TIMESTAMP()** to map two TIMESTAMP values to the same Unix timestamp value. **FROM_UNIXTIME()** will map that value back to only one of the original TIMESTAMP values. Here is an example, using TIMESTAMP values in the CET time zone:

```
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+---------------------------------------+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
| 1111885200 |
+---------------------------------------+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+---------------------------------------+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
| 1111885200 |
+---------------------------------------+
mysql> SELECT FROM_UNIXTIME(1111885200);
+---------------------------+
| FROM_UNIXTIME(1111885200) |
| 2005-03-27 03:00:00       |
+---------------------------+
```
If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See Section 12.10, “Cast Functions and Operators”.

- **UTC_DATE(), UTC_DATE()**

  Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```sql
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- **UTC_TIME(), UTC_TIME([fsp])**

  Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

  If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```sql
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- **UTC_TIMESTAMP, UTC_TIMESTAMP([fsp])**

  Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

  If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```sql
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- **WEEK(date[, mode])**

  This function returns the week number for `date`. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the `default_week_format` system variable is used. See Section 5.1.8, “Server System Variables”.

  The following table describes how the `mode` argument works.

<table>
<thead>
<tr>
<th>Mode</th>
<th>First day of week</th>
<th>Range</th>
<th>Week 1 is the first week</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sunday</td>
<td>0-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>1</td>
<td>Monday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>2</td>
<td>Sunday</td>
<td>1-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>3</td>
<td>Monday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>4</td>
<td>Sunday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>5</td>
<td>Monday</td>
<td>0-53</td>
<td>with a Monday in this year</td>
</tr>
<tr>
<td>6</td>
<td>Sunday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>7</td>
<td>Monday</td>
<td>1-53</td>
<td>with a Monday in this year</td>
</tr>
</tbody>
</table>
For `mode` values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```sql
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional `mode` argument:

```sql
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional `mode` argument.

```sql
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```sql
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- **WEEKDAY(date)**

  Returns the weekday index for `date` (0 = Monday, 1 = Tuesday, … 6 = Sunday).

```sql
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- **WEEKOFYEAR(date)**

  Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date, 3)`.

```sql
mysql> SELECT WEEKOFYEAR('2008-02-20');
```
What Calendar Is Used By MySQL?

12.8 What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar.*

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

<table>
<thead>
<tr>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
<th>Saturday</th>
<th>Sunday</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>15</td>
<td>16</td>
<td>17</td>
</tr>
<tr>
<td>18</td>
<td>19</td>
<td>20</td>
<td>21</td>
<td>22</td>
<td>23</td>
<td>24</td>
</tr>
<tr>
<td>25</td>
<td>26</td>
<td>27</td>
<td>28</td>
<td>29</td>
<td>30</td>
<td>31</td>
</tr>
</tbody>
</table>

There are no dates between October 4 and October 15. This discontinuity is called the *cutover.* Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic.* Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL *DATE* or *DATETIME* values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

12.9 Full-Text Search Functions

`MATCH (col1, col2, ...) AGAINST (expr [search_modifier])`
MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in Section 12.9.8, “ngram Full-Text Parser”, and Section 12.9.9, “MeCab Full-Text Parser Plugin”.
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (" characters. The stopword list applies. For more information about stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

  Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see Section 12.9.1, “Natural Language Full-Text Searches”.

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see Section 12.9.2, “Boolean Full-Text Searches”.

- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see Section 12.9.3, “Full-Text Searches with Query Expansion”.

For information about `FULLTEXT` query performance, see Section 8.3.5, “Column Indexes”.
For more information about InnoDB FULLTEXT indexes, see Section 15.6.2.4, “InnoDB FULLTEXT Indexes”.

Constraints on full-text searching are listed in Section 12.9.5, “Full-Text Restrictions”.

The myisam_ftdump utility dumps the contents of a MyISAM full-text index. This may be helpful for debugging full-text queries. See Section 4.6.3, “myisam_ftdump — Display Full-Text Index information”.

### 12.9.1 Natural Language Full-Text Searches

By default or with the IN NATURAL LANGUAGE MODE modifier, the MATCH() function performs a natural language search for a string against a text collection. A collection is a set of one or more columns included in a FULLTEXT index. The search string is given as the argument to AGAINST(). For each row in the table, MATCH() returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the MATCH() list.

```sql
mysql> CREATE TABLE articles ( id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, title VARCHAR(200), body TEXT, FULLTEXT (title,body) ) ENGINE=InnoDB;
Query OK, 0 rows affected (0.08 sec)

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.01 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
WHERE MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE);
+----+-------------------+------------------------------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>DBMS stands for DataBase ...</td>
</tr>
<tr>
<td>5</td>
<td>MySQL vs. YourSQL</td>
<td>In the following database comparison ...</td>
</tr>
<tr>
<td>----+-------------------+------------------------------------------</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)
```

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a case-sensitive or binary collation for the indexed columns. For example, a column that uses the utf8mb4 character set of can be assigned a collation of utf8mb4_0900_as_cs or utf8mb4_bin to make it case-sensitive for full-text searches.

When MATCH() is used in a WHERE clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

---

**Note**

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.
To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
    WHERE MATCH (title, body) AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

```
+----------+
| COUNT(*) |
+----------+
|        2 |
+----------+
1 row in set (0.00 sec)
```

You might find it quicker to rewrite the query as follows:

```
mysql> SELECT COUNT(IF(MATCH (title, body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL)) AS count
    FROM articles;
```

```
+-------+
| count  |
+-------+
|   2    |
+-------+
1 row in set (0.03 sec)
```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in Section 12.9.2, “Boolean Full-Text Searches”, and Section 12.9.3, “Full-Text Searches with Query Expansion”.

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title, body) AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
    FROM articles;
```

```
+----+---------------------+
| id | score               |
+----+---------------------+
|  1 | 0.22764469683170319 |
|  2 |                   0  |
|  3 | 0.22764469683170319 |
+----+---------------------+
```
The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title, body) AGAINST ('Security implications of running MySQL as root' IN NATURAL LANGUAGE MODE) AS score
FROM articles WHERE MATCH (title, body) AGAINST ('Security implications of running MySQL as root' IN NATURAL LANGUAGE MODE);
+----+---------------------+-----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>body</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>1. Never run mysqld as root. 2. ...</td>
<td>1.5219271183014</td>
</tr>
<tr>
<td>6</td>
<td>When configured properly, MySQL ...</td>
<td>1.3114095926285</td>
</tr>
</tbody>
</table>
+----+---------------------+-----------------+
2 rows in set (0.00 sec)
```

A phrase that is enclosed within double quote (""") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (""'), but not more than one in a row. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; 'aaa'bbb' would be parsed as aaa'bbb'.

The built-in `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index that uses the built-in `FULLTEXT` parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create `FULLTEXT` indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see Section 29.2, "The MySQL Plugin API". For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for InnoDB search indexes, or four characters for MyISAM. You can control the cutoff by setting a configuration option before creating the index: `innodb_ft_min_token_size` configuration option for InnoDB search indexes, or `ft_min_word_len` for MyISAM.
Note
This behavior does not apply to \texttt{FULLTEXT} indexes that use the ngram parser. For the ngram parser, token length is defined by the \texttt{ngram_token_size} option.

- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overridden by a user-defined list. The stopword lists and related configuration options are different for InnoDB search indexes and MyISAM ones. Stopword processing is controlled by the configuration options \texttt{innodb_ft_enable_stopword}, \texttt{innodb_ft_server_stopword_table}, and \texttt{innodb_ft_user_stopword_table} for InnoDB search indexes, and \texttt{ft_stopword_file} for MyISAM ones.

See Section 12.9.4, “Full-Text Stopwords” to view default stopword lists and how to change them. The default minimum word length can be changed as described in Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

MyISAM Limitation
For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on MyISAM tables. For example, although the word “MySQL” is present in every row of the \texttt{articles} table shown earlier, a search for the word in a MyISAM search index produces no results:

```sql
mysql> SELECT * FROM articles
WHERE MATCH (title,body) AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopword. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes InnoDB tables more suited to experimentation with full-text searches. If you create a MyISAM table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on InnoDB tables, or use the boolean search mode explained in Section 12.9.2, “Boolean Full-Text Searches”.

12.9.2 Boolean Full-Text Searches
MySQL can perform boolean full-text searches using the \texttt{IN BOOLEAN MODE} modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the + and – operators indicate that a word must be present or absent, respectively, for
Boolean Full-Text Searches

a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do not contain the word “YourSQL”:

```sql
mysql> SELECT * FROM articles WHERE MATCH (title,body) AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

+----+-----------------------+-------------------------------------+

+----+-----------------------+-------------------------------------+

Note

In implementing this feature, MySQL uses what is sometimes referred to as implied Boolean logic, in which

- `+` stands for **AND**
- `-` stands for **NOT**
- `[no operator]` implies **OR**

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.

- **InnoDB** tables require a **FULLTEXT** index on all columns of the **MATCH()** expression to perform boolean queries. Boolean queries against a **MyISAM** search index can work even without a **FULLTEXT** index, although a search executed in this fashion would be quite slow.

- The minimum and maximum word length full-text parameters apply to **FULLTEXT** indexes created using the built-in **FULLTEXT** parser and MeCab parser plugin. `innodb_ft_min_token_size` and `innodb_ft_max_token_size` are used for **InnoDB** search indexes. `ft_min_word_len` and `ft_max_word_len` are used for **MyISAM** search indexes.

Minimum and maximum word length full-text parameters do not apply to **FULLTEXT** indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

- The stopword list applies, controlled by `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for **InnoDB** search indexes, and `ft_stopword_file` for **MyISAM** ones.

- **InnoDB** full-text search does not support the use of multiple operators on a single search word, as in this example: `'+apple'`. Use of multiple operators on a single search word returns a syntax error to standard out. **MyISAM** full-text search will successfully process the same search ignoring all operators except for the operator immediately adjacent to the search word.

- **InnoDB** full-text search only supports leading plus or minus signs. For example, **InnoDB** supports `'+apple'` but does not support `'apple+'`. Specifying a trailing plus or minus sign causes **InnoDB** to report a syntax error.

- **InnoDB** full-text search does not support the use of a leading plus sign with wildcard (`'++'`), a plus and minus sign combination (`'+-'`), or leading a plus and minus sign combination (`'+-apple'`). These invalid queries return a syntax error.
• InnoDB full-text search does not support the use of the @ symbol in boolean full-text searches. The @ symbol is reserved for use by the @distance proximity search operator.

• They do not use the 50% threshold that applies to MyISAM search indexes.

The boolean full-text search capability supports the following operators:

• +

A leading or trailing plus sign indicates that this word must be present in each row that is returned. InnoDB only supports leading plus signs.

• –

A leading or trailing minus sign indicates that this word must not be present in any of the rows that are returned. InnoDB only supports leading minus signs.

Note: The – operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by – returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

• (no operator)

By default (when neither + nor – is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of MATCH() ... AGAINST() without the IN BOOLEAN MODE modifier.

• @distance

This operator works on InnoDB tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the @distance operator, for example, MATCH(col1) AGAINST("word1 word2 word3" @8' IN BOOLEAN MODE)

• > <

These two operators are used to change a word’s contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

• ( )

Parentheses group words into subexpressions. Parenthesized groups can be nested.

• ~

A leading tilde acts as a negation operator, causing the word’s contribution to the row’s relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the – operator.

• *

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is appended to the word to be affected. Words match if they begin with the word preceding the * operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the innodb_ft_min_token_size setting for InnoDB tables, or ft_min_word_len for MyISAM tables. These options are not applicable to FULLTEXT indexes that use the ngram parser.
The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for "+word the*" could return fewer rows than a search for "+word the", because the second query ignores the too-short search term the.

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase".

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- 'apple banana'
  Find rows that contain at least one of the two words.

- '+apple +juice'
  Find rows that contain both words.

- '+apple macintosh'
  Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- '+apple ~macintosh'
  Find rows that contain the word “apple” but not “macintosh”.

- '+apple ~macintosh'
  Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for '+apple ~macintosh', for which the presence of “macintosh” causes the row not to be returned at all.

- '+apple +(>turnover <strudel)'
  Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- 'apple*'
  Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- "some words"
  Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the " characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.
InnoDB full-text search is modeled on the Sphinx full-text search engine, and the algorithms used are based on BM25 and TF-IDF ranking algorithms. For these reasons, relevancy rankings for InnoDB boolean full-text search may differ from MyISAM relevancy rankings.

InnoDB uses a variation of the “term frequency-inverse document frequency” (TF-IDF) weighting system to rank a document’s relevance for a given full-text search query. The TF-IDF weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

How Relevancy Ranking is Calculated

The term frequency (TF) value is the number of times that a word appears in a document. The inverse document frequency (IDF) value of a word is calculated using the following formula, where total_records is the number of records in the collection, and matching_records is the number of records that the search term appears in.

$$ IDF = \log_{10}( \frac{\text{total_records}}{\text{matching_records}}) $$

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

$$ \text{TF} \times \text{IDF} $$

Using the TF and IDF values, the relevancy ranking for a document is calculated using this formula:

$$ \text{rank} = \text{TF} \times \text{IDF} \times \text{IDF} $$

The formula is demonstrated in the following examples.

Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.
There are 8 records in total, with 3 that match the “database” search term. The first record (id 6) contains the search term 6 times and has a relevancy ranking of 1.0886961221694946. This ranking value is calculated using a TF value of 6 (the “database” search term appears 6 times in record id 6) and an IDF value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

\[$IDF = \log_{10} \left( \frac{8}{3} \right) = 0.42596873216370745$\]

The TF and IDF values are then entered into the ranking formula:

\[rank = TF \times IDF \times IDF\]

Performing the calculation in the MySQL command-line client returns a ranking value of 1.088696164686938.

Note

You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client (1.0886961221694946 versus 1.088696164686938). The difference is due to how the casts between integers and floats/doubles are performed internally by InnoDB (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the `articles` table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

\[rank = TF \times IDF \times IDF + TF \times IDF \times IDF\]

Performing a search on two terms (‘mysql tutorial’) returns the following results:
In the first record (id 8), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

```sql
mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));
+-------------------------------------------------------+
<table>
<thead>
<tr>
<th>(1*log10(8/6)<em>log10(8/6)) + (2</em>log10(8/2)*log10(8/2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.7405621541938003</td>
</tr>
</tbody>
</table>
+-------------------------------------------------------+
```

Note

The slight difference in the ranking values returned by the SELECT ... MATCH ... AGAINST statement and the MySQL command-line client is explained in the preceding example.

### 12.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```sql
mysql> SELECT * FROM articles
    WHERE MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

```
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
+----+-------------------+------------------------------------------+
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT * FROM articles
    WHERE MATCH (title,body) AGAINST ('database' WITH QUERY EXPANSION);
```

```
+----+-----------------------+------------------------------------------+
| id | title                 | body                                     |
+----+-----------------------+------------------------------------------+
|  1 | MySQL Tutorial        | DBMS stands for DataBase ...             |
|  5 | MySQL vs. YourSQL     | In the following database comparison ... |
|  7 | 1001 MySQL Tricks     | 1. Never run mysqld as root. 2. ...      |
|  6 | Database, Database,   | database database database               |
|  7 | 1001 MySQL Tricks     | 1. Never run mysqld as root. 2. ...      |
|  6 | Database, Database,   | database database database               |
+----+-----------------------+------------------------------------------+
```

2 rows in set (0.00 sec)
Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell "Maigret". A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

**Note**

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

### 12.9.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case insensitive if the collation is `utf8mb4_0900_ai_ci`, whereas lookups are case-sensitive if the collation is `utf8mb4_0900_as_cs` or `utf8mb4_bin`.

- **Stopwords for InnoDB Search Indexes**
- **Stopwords for MyISAM Search Indexes**

#### Stopwords for InnoDB Search Indexes

**InnoDB** has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default **InnoDB** stopword list, query the `INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD` table.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-------+
| value |
+-------+
| a     |
| about |
| an    |
| are   |
| as    |
| at    |
| be    |
| by    |
| com   |
| de    |
| en    |
| for   |
```

---

1909
To define your own stopword list for all InnoDB tables, define a table with the same structure as the `INNODB_FT_DEFAULT_STOPWORD` table, populate it with stopwords, and set the value of the `innodb_ft_server_stopword_table` option to a value in the form `db_name/table_name` before creating the full-text index. The stopword table must have a single `VARCHAR` column named `value`. The following example demonstrates creating and configuring a new global stopword table for InnoDB.

```sql
-- Create a new stopword table
mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopword is used in this example)
mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table
mysql> CREATE TABLE opening_lines (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, opening_line TEXT(500), author VARCHAR(200), title VARCHAR(200)) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table
mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES ('Call me Ishmael.','Herman Melville','Moby-Dick'), ('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'), ('I am an invisible man.','Ralph Ellison','Invisible Man'), ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'), ('It was love at first sight.','Joseph Heller','Catch-22'), ('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'), ('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'), ('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
```
-- Set the innodb_ft_server_stopword_table option to the new stopword table

mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)

mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 1

Verify that the specified stopword ('Ishmael') does not appear by querying the words in
INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE.

Note

By default, words less than 3 characters in length or greater than 84 characters in
length do not appear in an InnoDB full-text search index. Maximum and minimum
word length values are configurable using the innodb_ft_max_token_size and
innodb_ft_min_token_size variables. This default behavior does not apply to
the ngram parser plugin. ngram token size is defined by the ngram_token_size
option.

mysql> SET GLOBAL innodb_ft_aux_table='test/opening_lines';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT word FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 15;
+-----------+
| word      |
+-----------+
| across    |
| all       |
| burn      |
| buy       |
| call      |
| comes     |
| dalloway  |
| first     |
| flowers   |
| happened  |
| herself   |
| invisible |
| less      |
| love      |
| man       |
+-----------+
15 rows in set (0.00 sec)

To create stopword lists on a table-by-table basis, create other stopword tables and use the
innodb_ft_user_stopword_table option to specify the stopword table that you want to use before
you create the full-text index.

Stopwords for MyISAM Search Indexes

The stopword file is loaded and searched using latin1 if character_set_server is ucs2, utf16,
utf16le, or utf32.

To override the default stopword list for MyISAM tables, set the ft_stopword_file system variable.
(See Section 5.1.8, “Server System Variables”.) The variable value should be the path name of the file
containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file
in the data directory unless an absolute path name is given to specify a different directory. After changing
Full-Text Stopwords

the value of this variable or the contents of the stopword file, restart the server and rebuild your FULLTEXT indexes.

The stopword list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (\_) and a single apostrophe ('\) which are treated as part of a word. The character set of the stopword list is the server's default character set; see Section 10.3.2, "Server Character Set and Collation".

The following list shows the default stopwords for MyISAM search indexes. In a MySQL source distribution, you can find this list in the storage/myisam/ft_static.c file.

### 12.9.5 Full-Text Restrictions

- Full-text searches are supported for **InnoDB** and **MyISAM** tables only.

- Full-text searches are not supported for partitioned tables. See [Section 23.6, “Restrictions and Limitations on Partitioning”](#).

- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the **utf8** character set can be used, but not the **ucs2** character set. Although **FULLTEXT** indexes on **ucs2**
columns cannot be used, you can perform `IN BOOLEAN MODE` searches on a `ucs2` column that has no such index.

The remarks for `utf8` also apply to `utf8mb4`, and the remarks for `ucs2` also apply to `utf16`, `utf16le`, and `utf32`.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser cannot determine where words begin and end in these and other such languages.

A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with `InnoDB` and `MyISAM` tables.

- Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.

- The `MATCH()` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is `IN BOOLEAN MODE` on a `MyISAM` table. For `MyISAM` tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.

- The argument to `AGAINST()` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

- Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See Section 8.9.4, “Index Hints”.

- For `InnoDB`, all DML operations (`INSERT`, `UPDATE`, `DELETE`) involving columns with full-text indexes are processed at transaction commit time. For example, for an `INSERT` operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.

- The ‘%’ character is not a supported wildcard character for full-text searches.

## 12.9.6 Fine-Tuning MySQL Full-Text Search

MySQL’s full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.9, “Installing MySQL from Source”.

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

- Configuring Minimum and Maximum Word Length
- Configuring the Natural Language Search Threshold
- Modifying Boolean Full-Text Search Operators
- Character Set Modifications
- Rebuilding InnoDB Full-Text Indexes
- Optimizing InnoDB Full-Text Indexes
Fine-Tuning MySQL Full-Text Search

- Rebuilding MyISAM Full-Text Indexes

Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the `innodb_ft_min_token_size` and `innodb_ft_max_token_size` for InnoDB search indexes, and `ft_min_word_len` and `ft_max_word_len` for MyISAM ones.

**Note**

Minimum and maximum word length full-text parameters do not apply to FULLTEXT indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

After changing any of these options, rebuild your FULLTEXT indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```ini
[mysqld]
inno_db_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your FULLTEXT indexes. For MyISAM tables, note the remarks regarding `myisamchk` in the instructions that follow for rebuilding MyISAM full-text indexes.

Configuring the Natural Language Search Threshold

For MyISAM search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```c
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```c
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

**Note**

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on MyISAM tables, set the `ft_boolean_syntax` system variable. (InnoDB does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”). No rebuilding of indexes is necessary in this case.

Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each
table that contains any FULLTEXT indexes. Suppose that you want to treat the hyphen character (’-’) as a word character. Use one of these methods:

- **Modify the MySQL source:** In `storage/innobase/handler/ha_innodb.cc` (for InnoDB), or in `storage/myisam/ftdefs.h` (for MyISAM), see the `true_word_char()` and `misc_word_char()` macros. Add ‘-’ to one of those macros and recompile MySQL.

- **Modify a character set file:** This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype>` array in one of the character set XML files to specify that ‘-’ is a “letter.” Then use the given character set for your FULLTEXT indexes. For information about the `<ctype>` array format, see Section 10.12.1, “Character Definition Arrays”.

- **Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation.** For general information about adding collations, see Section 10.13, “Adding a Collation to a Character Set”. For an example specific to full-text indexing, see Section 12.9.7, “Adding a Collation for Full-Text Indexing”.

### Rebuilding InnoDB Full-Text Indexes

For the changes to take effect, FULLTEXT indexes must be rebuilt after modifying any of the following full-text index variables: `innodb_ft_min_token_size`; `innodb_ft_max_token_size`; `innodb_ft_server_stopword_table`; `innodb_ft_user_stopword_table`; `innodb_ft_enable_stopword`; `ngram_token_size`. Modifying `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` requires restarting the server.

To rebuild FULLTEXT indexes for an InnoDB table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

### Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)

mysql> OPTIMIZE TABLE opening_lines;
+--------------------+----------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.opening_lines</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+--------------------+----------+----------+----------+
1 row in set (0.01 sec)
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time `OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

### Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopword file itself, you must rebuild your FULLTEXT indexes after making the changes and restarting the server.
To rebuild the `FULLTEXT` indexes for a `MyISAM` table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies `MyISAM` table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the `default` full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for `MyISAM` table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

## 12.9.7 Adding a Collation for Full-Text Indexing

This section describes how to add a new collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `'-'` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in Section 10.13, “Adding a Collation to a Character Set”; it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in Section 10.13, “Adding a Collation to a Character Set”, can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The collation ID must be unused, so choose a value different from 1000 if that ID is already taken on your system.
Adding a Collation for Full-Text Indexing

<charset name="latin1">
  ...
<collation name="latin1_fulltext_ci" id="1000"/>
</charset>

2. Declare the sort order for the collation in the latin1.xml file. In this case, the order can be copied from latin1_swedish_ci:

<collation name="latin1_fulltext_ci">
  <map>
  00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
  10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
  20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
  30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
  40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
  50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
  60 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
  50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
  80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
  90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
  A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
  B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
  41 41 41 41 4C 4B 4C 43 45 45 45 45 49 49 49 49
  44 4E 4F 4F 4F 4F 5D 57 D8 55 55 55 59 59 59 59
  41 41 41 41 4C 4B 4C 43 45 45 45 45 49 49 49 49
  44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 59 59
  </map>
</collation>

3. Modify the ctype array in latin1.xml. Change the value corresponding to 0x2D (which is the code for the '-' character) from 10 (punctuation) to 01 (small letter). In the following array, this is the element in the fourth row down, third value from the end.

<ctype>
  <map>
  00
  20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
  20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
  48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
  84 84 84 84 84 84 84 84 84 84 44 10 10 10 10 10
  10 81 81 81 81 81 81 01 01 01 01 01 01 01 01 01
  01 01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
  01 01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
  01 01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
  10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
  02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
  02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
  02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
  </map>
</ctype>

4. Restart the server.

5. To employ the new collation, include it in the definition of columns that are to use it:

```sql
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)
mysql> CREATE TABLE t1 (  
```

1918
12.9.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with InnoDB and MyISAM.

An ngram is a contiguous sequence of \( n \) characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of \( n \) characters. For example, you can tokenize “abcd” for different values of \( n \) using the ngram full-text parser.

\[
\begin{align*}
\text{n=1:} & \quad 'a', 'b', 'c', 'd' \\
\text{n=2:} & \quad 'ab', 'bc', 'cd' \\
\text{n=3:} & \quad 'abc', 'bcd' \\
\text{n=4:} & \quad 'abcd'
\end{align*}
\]

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in Section 12.9, “Full-Text Search Functions” applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration options, except for minimum and maximum word length options (innodb_ft_min_token_size, innodb_ft_max_token_size, ft_min_word_len, ft_max_word_len) are also applicable.

**Configuring ngram Token Size**

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the ngram_token_size configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, ngram_token_size is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set ngram_token_size to 1. A smaller token size produces
a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set `ngram_token_size` accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set `ngram_token_size` to a value of 2 or higher.

As a read-only variable, `ngram_token_size` may only be set as part of a startup string or in a configuration file:

- **Startup string:**
  ```
  mysqld --ngram_token_size=2
  ```

- **Configuration file:**
  ```
  [mysqld]
  ngram_token_size=2
  ```

**Note**
The following minimum and maximum word length configuration options are ignored for FULLTEXT indexes that use the ngram parser: `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, and `ft_max_word_len`.

### Creating a FULLTEXT Index that Uses the ngram Parser

To create a FULLTEXT index that uses the ngram parser, specify WITH PARSER ngram with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

The following example demonstrates creating a table with an `ngram` FULLTEXT index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table.

MySQL> USE test;

MySQL> CREATE TABLE articles (  
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
  title VARCHAR(200),  
  body TEXT,  
  FULLTEXT (title, body) WITH PARSER ngram  
) ENGINE=InnoDB CHARACTER SET utf8mb4;

MySQL> SET NAMES utf8mb4;

MySQL> INSERT INTO articles (title, body) VALUES  
  ('数据库管理', '在本教程中我将向你展示如何管理数据库'),  
  ('数据库应用开发', '学习开发数据库应用程序');

MySQL> SET GLOBAL innodb_ft_aux_table="test/articles";

MySQL> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;

To add a FULLTEXT index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

MySQL> CREATE TABLE articles (  
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
  title VARCHAR(200),  
  body TEXT  
) ENGINE=InnoDB CHARACTER SET utf8;

MySQL> ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title, body) WITH PARSER ngram;
ngram Full-Text Parser

* Or:

```sql
CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSER ngram;
```

**ngram Parser Space Handling**

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

**ngram Parser Stopword Handling**

The built-in MySQL full-text parser compares words to entries in the stopword list. If a word is equal to an entry in the stopword list, the word is excluded from the index. For the ngram parser, stopword handling is performed differently. Instead of excluding tokens that are equal to entries in the stopword list, the ngram parser excludes tokens that contain stopwords. For example, assuming `ngram_token_size=2`, a document that contains “a,b” is parsed to “a,” and “,b”. If a comma (“,”) is defined as a stopword, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopword list, which contains a list of English stopwords. For a stopword list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopword list, see Section 12.9.4, “Full-Text Stopwords”.

Stopwords greater in length than `ngram_token_size` are ignored.

**ngram Parser Term Search**

For natural language mode search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming `ngram_token_size=2`) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For boolean mode search, the search term is converted to an ngram phrase search. For example, the string ‘abc’ (assuming `ngram_token_size=2`) is converted to “ab bc”. Given two documents, one containing ‘ab’ and the other containing ‘abc’, the search phrase “ab bc” only matches the document containing ‘abc’.

**ngram Parser Wildcard Search**

Because an ngram FULLTEXT index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram FULLTEXT search indexes:

- If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on “a*” returns all rows starting with “a”.

- If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an “abc*” wildcard search is converted to “ab bc”.

**ngram Parser Phrase Search**

Phrase searches are converted to ngram phrase searches. For example, The search phrase “abc” is converted to “ab bc”, which returns documents containing “abc” and “ab bc”.

1921
The search phrase “abc def” is converted to “ab bc de ef”, which returns documents containing “abc def” and “ab bc de ef”. A document that contains “abcdef” is not returned.

12.9.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with InnoDB and MyISAM.

Note

MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see Section 12.9.8, “ngram Full-Text Parser”.

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes “データベース管理” ("Database Management") into “データベース” ("Database") and “管理” ("Management"). By comparison, the ngram full-text parser tokenizes text into a contiguous sequence of $n$ characters, where $n$ represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in Section 12.9, “Full-Text Search Functions” applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the MeCab: Yet Another Part-of-Speech and Morphological Analyzer project on Github.

Installing the MeCab Parser Plugin

The MeCab parser plugin requires mecab and mecab-ipadic.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system mecab version is too old), MySQL dynamically links to the system mecab installation if it is installed to the default location. On other supported Unix-like platforms, libmecab.so is statically linked in libpluginmecab.so, which is located in the MySQL plugin directory. mecab-ipadic is included in MySQL binaries and is located in MYSQL_HOME\lib\mecab.

You can install mecab and mecab-ipadic using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build mecab and mecab-ipadic from source. For information about installing mecab and mecab-ipadic using a native package management utility, see Installing MeCab From a Binary Distribution (Optional). If you want to build mecab and mecab-ipadic from source, see Building MeCab From Source (Optional).

On Windows, libmecab.dll is found in the MySQL bin directory. mecab-ipadic is located in MYSQL_HOME/lib/mecab.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the mecab_rc_file configuration option to the location of the mecabrc configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the mecabrc file is located in MYSQL_HOME/lib/mecab/etc/.
The `loose` prefix is an option modifier. The `mecab_rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

For information about the MySQL configuration file and its location, see Section 4.2.7, “Using Option Files”.

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For InnoDB tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For MyISAM tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains and entry similar to the following:

   ```
   dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
   ```

   To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

   ```
   dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
   ```

   If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file will differ, as will the dictionaries and their location.

3. After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

   - The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpms` character sets.
   - The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets.
   - The `ipadic_utf-8` dictionary supports the `utf8` and `utf8mb4` character sets.

   `mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.

5. Install the MeCab parser plugin:
The MeCab parser plugin is installed using `INSTALL PLUGIN` syntax. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

```
INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';
```

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

```
mysql> SHOW PLUGINS;
```

A `mecab` plugin should appear in the list of plugins.

### Creating a FULLTEXT Index that uses the MeCab Parser

To create a `FULLTEXT` index that uses the mecab parser, specify `WITH PARSER ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

This example demonstrates creating a table with a `mecab FULLTEXT` index, inserting sample data, and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table:

```
mysql> USE test;
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body) WITH PARSER mecab
) ENGINE=InnoDB CHARACTER SET utf8;
mysql> SET NAMES utf8;
mysql> INSERT INTO articles (title,body) VALUES
  ('データベース管理','このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),
  ('データベースアプリケーション開発','データベースアプリケーションを開発することを学ぶ');
mysql> SET GLOBAL innodb_ft_aux_table="test/articles";
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a `FULLTEXT` index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```
CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER mecab;
```

```
# Or:
CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSER mecab;
```

### MeCab Parser Space Handling

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes `データベース管理 as データベース and 管理`.
MeCab Full-Text Parser Plugin

MeCab Parser Stopword Handling

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

MeCab Parser Term Search

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

MeCab Parser Wildcard Search

Wildcard search terms are not tokenized. A search on データベース管理* is performed on the prefix, データベース管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理*' IN BOOLEAN MODE);
```

MeCab Parser Phrase Search

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

Installing MeCab From a Binary Distribution (Optional)

This section describes how to install mecab and mecab-ipadic from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
apt-get install mecab
apt-get install mecab-ipadic
```

Installing MeCab From Source (Optional)

If you want to build mecab and mecab-ipadic from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for mecab and mecab-ipadic from http://taku910.github.io/mecab/#download. As of February, 2016, the latest available packages are mecab-0.996.tar.gz and mecab-ipadic-2.7.0-20070801.tar.gz.

2. Install mecab:

```
tar xzvf mecab-0.996.tar
cd mecab-0.996
./configure
make
make check
su
make install
```
3. Install `mecab-ipadic`:

```bash
tar zxfv mecab-ipadic-2.7.0-20070801.tar
cd mecab-ipadic-2.7.0-20070801
./configure
make
su
make install
```

4. Compile MySQL using the `WITH_MECAB` CMake option. Set the `WITH_MECAB` option to `system` if you have installed `mecab` and `mecab-ipadic` to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set `WITH_MECAB` to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

12.10 Cast Functions and Operators

Table 12.14 Cast Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>Cast a string to a binary string</td>
</tr>
<tr>
<td>CAST()</td>
<td>Cast a value as a certain type</td>
</tr>
<tr>
<td>CONVERT()</td>
<td>Cast a value as a certain type</td>
</tr>
</tbody>
</table>

Cast functions and operators enable conversion of values from one data type to another.

`CONVERT()` with a `USING` clause provides a way to convert data between different character sets:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8_table (utf8_column)
  SELECT CONVERT(latin1_column USING utf8) FROM latin1_table;
```

You can also use `CONVERT()` without `USING` or `CAST()` to convert strings between different character sets:

```
CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)
```

Examples:

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8);
SELECT CAST('test' AS CHAR CHARACTER SET utf8);
```

If you specify `CHARACTER SET charset_name` as just shown, the resulting character set and collation are `charset_name` and the default collation of `charset_name`. If you omit `CHARACTER SET charset_name`, the resulting character set and collation are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”).
A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, this is legal:

```sql
SELECT CAST('test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

But this is illegal:

```sql
SELECT CAST('test' AS CHAR CHARACTER SET utf8 COLLATE utf8_bin);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the binary character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result character set has a case-insensitive collation, a `LIKE` operation is not case-sensitive:

```sql
SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statement. To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```sql
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci FROM tbl_name;
```

`CONVERT()` and `CAST()` can be used more generally for comparing strings that are represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```sql
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (latin2_general_ci,IMPLICIT) for operation '='
```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```sql
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+------------------+
| @s1 = CONVERT(@s2 USING latin1) |
+------------------+
| 1 |
```

For string literals, another way to specify the character set is to use a character set introducer (`_latin1` and `_latin2` in the preceding example are instances of introducers). Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see Section 10.3.8, “Character Set Introducers”.

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string:

```sql
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+------------------+------------------+
| @str             | @str             |
+------------------+------------------+
| {binary}         | {string}         |
```

1927
Cast Functions and Operators

<table>
<thead>
<tr>
<th>LOWER(@str)</th>
<th>LOWER(CONVERT(@str USING utf8mb4))</th>
</tr>
</thead>
<tbody>
<tr>
<td>New York</td>
<td>new york</td>
</tr>
</tbody>
</table>

If you convert an indexed column using `BINARY`, `CAST()`, or `CONVERT()`, MySQL may not be able to use the index efficiently.

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```sql
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
```

```sql
mysql> SHOW CREATE TABLE new_table\G
```

```
*************************** 1. row ***************************
Table: new_table
Create Table: CREATE TABLE `new_table` (  `c1` date DEFAULT NULL ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```sql
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ',CAST(NOW() AS DATE))`.

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See Section 12.7, "Date and Time Functions".

To cast a string to a number, you normally need do nothing other than use the string value in numeric context:

```sql
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```sql
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```sql
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see Section 12.2, "Type Conversion in Expression Evaluation".

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see
Section 12.6.1, “Arithmetic Operators”). To override this, use the \texttt{SIGNED} or \texttt{UNSIGNED} cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

\begin{verbatim}
mysql> SELECT 1 - 2;
   -> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
   -> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
   -> -1
\end{verbatim}

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, \texttt{DECIMAL} column values are regarded as floating-point values.)

\begin{verbatim}
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
   -> -1.0
\end{verbatim}

The SQL mode affects the result of conversion operations (see Section 5.1.11, “Server SQL Modes”). Examples:

- For conversion of a “zero” date string to a date, \texttt{CONVERT()} and \texttt{CAST()} return \texttt{NULL} and produce a warning when the \texttt{NO_ZERO_DATE} SQL mode is enabled.

- For integer subtraction, if the \texttt{NO_UNSIGNED_SUBTRACTION} SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

The following list describes the available cast functions and operators:

- \texttt{BINARY \textit{expr}}

  The \texttt{BINARY} operator converts the expression to a binary string. A common use for \texttt{BINARY} is to force a character string comparison to be done byte by byte rather than character by character, in effect becoming case-sensitive. The \texttt{BINARY} operator also causes trailing spaces in comparisons to be significant.

\begin{verbatim}
mysql> SELECT 'a' = 'A';
   -> 1
mysql> SELECT BINARY 'a' = 'A';
   -> 0
mysql> SELECT 'a' = 'a ';
   -> 1
mysql> SELECT BINARY 'a' = 'a ';
   -> 0
\end{verbatim}

In a comparison, \texttt{BINARY} affects the entire operation; it can be given before either operand with the same result.

For purposes of converting a string expression to a binary string, these constructs are equivalent:

\begin{verbatim}
BINARY \textit{expr}
CAST(\textit{expr} AS BINARY)
CONVERT(\textit{expr} USING BINARY)
\end{verbatim}

If a value is a string literal, it can be designated as a binary string without performing any conversion by using the \texttt{_binary} character set introducer:

\begin{verbatim}
mysql> SELECT 'a' = 'A';
   -> 1
mysql> SELECT _binary 'a' = 'A';
\end{verbatim}
For information about introducers, see Section 10.3.8, “Character Set Introducers”.

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. A character column defined with the `BINARY` attribute is assigned table default character set and the binary (\_bin) collation of that character set. Every nonbinary character set has a \_bin collation. For example, the binary collation for the `utf8` character set is `utf8_bin`, so if the table default character set is `utf8`, these two column definitions are equivalent:

```sql
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```sql
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

- **CAST(expr AS type)**

  The `CAST()` function takes an expression of any type and produces a result value of the specified type, similar to `CONVERT()`. For more information, see the description of `CONVERT()`.

  `CAST()` is standard SQL syntax.

- **CONVERT(expr, type), CONVERT(expr USING transcoding_name)**

  The `CONVERT()` function takes an expression of any type and produces a result value of the specified type.

  Discussion of `CONVERT(expr, type)` syntax here also applies to `CAST(expr AS type)`, which is equivalent.

  `CONVERT(... USING ...)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

  `CONVERT()` with `USING` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the `utf8` character set:

  ```sql
  SELECT CONVERT('abc' USING utf8);
  ```

  `CONVERT()` without `USING` and `CAST()` take an expression and a `type` value specifying the result type. These `type` values are permitted:

  - **BINARY[(N)]**

    Produces a string with the `BINARY` data type. See Section 11.4.2, “The BINARY and VARBINARY Types” for a description of how this affects comparisons. If the optional length `N` is given, `BINARY(N)`
causes the cast to use no more than $N$ bytes of the argument. Values shorter than $N$ bytes are padded with 0x00 bytes to a length of $N$.

- **CHAR[($N$)] [charset_info]**

  Produces a string with the CHAR data type. If the optional length $N$ is given, CHAR($N$) causes the cast to use no more than $N$ characters of the argument. No padding occurs for values shorter than $N$ characters.

  With no charset_info clause, CHAR produces a string with the default character set. To specify the character set explicitly, these charset_info values are permitted:

  - **CHARACTER SET charset_name**:
    Produces a string with the given character set.

  - **ASCII**: Shorthand for CHARACTER SET latin1.

  - **UNICODE**: Shorthand for CHARACTER SET ucs2.

  In all cases, the string has the default collation for the character set.

- **DATE**

  Produces a DATE value.

- **DATETIME**

  Produces a DATETIME value.

- **DECIMAL[($M[,D])]**

  Produces a DECIMAL value. If the optional $M$ and $D$ values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale).

- **JSON**

  Produces a JSON value. For details on the rules for conversion of values between JSON and other types, see Comparison and Ordering of JSON Values.

- **NCHAR[($N$)]**

  Like CHAR, but produces a string with the national character set. See Section 10.3.7, “The National Character Set”.

  Unlike CHAR, NCHAR does not permit trailing character set information to be specified.

- **SIGNED [INTEGER]**

  Produces a signed integer value.

- **TIME**

  Produces a TIME value.

- **UNSIGNED [INTEGER]**

  Produces an unsigned integer value.
XML Functions

12.11 XML Functions

Table 12.15 XML Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExtractValue()</td>
<td>Extract a value from an XML string using XPath notation</td>
</tr>
<tr>
<td>UpdateXML()</td>
<td>Return replaced XML fragment</td>
</tr>
</tbody>
</table>

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the mysql and mysqldump clients by invoking them with the --xml option. See Section 4.5.1, "mysql — The MySQL Command-Line Client", and Section 4.5.4, "mysqldump — A Database Backup Program".

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the XML Path Language (XPath) 1.0 standard for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 8.0 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the MySQL XML User Forum.

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax $@variable_name (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) $@myvariable is used where $@myvariable was intended.

Example:

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>'; Query OK, 0 rows affected (0.00 sec)
mysql> SET @i =1, @j = 2; Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');
+-----+------------------+
| @i  | ExtractValue(@xml, '//b[$@i]') |
|-----+------------------|
| 1   | X                |
+-----+------------------+
1 row in set (0.00 sec)
mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');
+-----+------------------+
| @j  | ExtractValue(@xml, '//b[$@j]') |
|-----+------------------|
|     |                  |
+-----+------------------+
```
XML Functions

Variables in stored programs (strong checking). Variables using the syntax `$variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
-> DECLARE i INT DEFAULT 1;
-> DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>'; 
-> WHILE i < 4 DO
-> SELECT xml, i, ExtractValue(xml, '//a[$i]');
-> SET i = i+1;
-> END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> CALL myproc();
```

<table>
<thead>
<tr>
<th>xml</th>
<th>i</th>
<th>ExtractValue(xml, '//a[$i]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;a&gt;X&lt;/a&gt;&lt;a&gt;Y&lt;/a&gt;&lt;a&gt;Z&lt;/a&gt;</td>
<td>1</td>
<td>X</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)

<table>
<thead>
<tr>
<th>xml</th>
<th>i</th>
<th>ExtractValue(xml, '//a[$i]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;a&gt;X&lt;/a&gt;&lt;a&gt;Y&lt;/a&gt;&lt;a&gt;Z&lt;/a&gt;</td>
<td>2</td>
<td>Y</td>
</tr>
</tbody>
</table>
1 row in set (0.01 sec)

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.
Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

**Note**

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- ExtractValue(xml_frag, xpath_expr)

ExtractValue() takes two string arguments, a fragment of XML markup xml_frag and an XPath expression xpath_expr (also known as a locator); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the xpath_expr after appending /text(). In other words, ExtractValue('<a><b>Sakila</b></a>', '/a/b') and ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()') produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit /text())—for whatever reason, as long as xpath_expr is valid, and xml_frag consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in xml_frag or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath count() function. For example, both of these statements return an empty string, as shown here:

```sql
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><b/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><c/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```sql
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-------------------------------------+
| 1                                   |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)
```
XML Functions

Important

ExtractValue() returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
    -> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
```

```
+------+------+------+------+---------+
| val1 | val2 | val3 | val4 | val5    |
+------+------+------+------+---------+
| ccc  | ddd  | ddd  |      | ddd eee |
+------+------+------+------+---------+
```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see Section 10.8.4, "Collation Coercibility in Expressions", for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
```

```
| ExtractValue('<a>c</a><b', '//a') |
+-----------------------------------+
| NULL                              |
+-----------------------------------+
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning

```

```
| ExtractValue('<a>c</a><b/>', '//a') |
+-------------------------------------+
| c                                   |
+-------------------------------------+
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
```

UpdateXML(xml_target, xpath_expr, new_xml)
This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

```sql
mysql> SELECT
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
    -> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
    -> END;
```

```plaintext
*************************** 1. row ***************************
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

**Note**

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the XML Path Language (XPath) 1.0 specification for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

  Matches `<tag/>` if and only if `<tag/>` is the root element.

  Example: `/a` has a match in `<a><b/></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a/></b>` because in this instance it is the child of another element.

- `/tag1/tag2`

  Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

  Example: `/a/b` matches the `b` element in the XML fragment `<a><b/></a>` because it is a child of the root element `a`. It does not have a match in `<b><a/></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b/></c></a>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

  This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c/></b></a>`.

- `//tag`

  Matches any instance of `<tag>`.

  Example: `//a` matches the `a` element in any of the following: `<a><b><c/></b></a>; <c><a><b/></a></c><b><a/></b>`.

1936
// can be combined with /. For example, //a/b matches the b element in either of the fragments <a><b/></a> or <c><a><b/></a></c>.

**Note**

//tag is the equivalent of /descendant-or-self::*//tag. A common error is to confuse this with /descendant-or-self::*tag, although the latter expression can actually lead to very different results, as can be seen here:

```sql
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @xml;
+-----------------------------------------+
| @xml                                    |
+-----------------------------------------+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a> |
+-----------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT ExtractValue(@xml, '//b[1]');
+------------------------------+
| ExtractValue(@xml, '//b[1]') |
+------------------------------+
| x z                          |
+------------------------------+
1 row in set (0.00 sec)
mysql> SELECT ExtractValue(@xml, '//b[2]');
+------------------------------+
| ExtractValue(@xml, '//b[2]') |
+------------------------------+
|                              |
+------------------------------+
1 row in set (0.01 sec)
mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[1]');
+---------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[1]') |
+---------------------------------------------------+
| x z                                               |
+---------------------------------------------------+
1 row in set (0.06 sec)
mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[2]');
+---------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[2]') |
+---------------------------------------------------+
|                                                   |
+---------------------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[1]');
+-------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[1]') |
+-------------------------------------------------+
| z                                               |
+-------------------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[2]');
+-------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[2]') |
+-------------------------------------------------+
```
XML Functions

```
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-------------------------------------------------+
| x                                               |
+-------------------------------------------------+
1 row in set (0.00 sec)
```

• The * operator acts as a "wildcard" that matches any element. For example, the expression */b matches the b element in either of the XML fragments <a><b/></a> or <c><b/></c>. However, the expression does not produce a match in the fragment <b><a/></b> because b must be a child of some other element. The wildcard may be used in any position: The expression */b/* will match any child of a b element that is itself not the root element.

• You can match any of several locators using the | (UNION) operator. For example, the expression //b//* matches all b and c elements in the XML target.

• It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax tag[@attribute="value"]. For example, the expression //b[@id="idB"] matches the second b element in the fragment <a><b id="idA"/></c><b id="idB"/></a>. To match against any element having attribute="value", use the XPath expression //*[@attribute="value"].

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression //b[@c="x"][@d="y"] matches the element <b c="x" d="y"/> occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the | operator. For example, to match all b elements whose c attributes have either of the values 23 or 17, use the expression //b[@c="23"]|//b[@c="17"]. You can also use the logical or operator for this purpose: //b[@c="23" or @c="17"].

```
Note
The difference between or and | is that or joins conditions, while | joins result sets.
```

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

• Nodeset-to-nodeset comparison (such as '/a/b[@c=@d]') is not supported.

• All of the standard XPath comparison operators are supported. (Bug #22823)

• Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
    -> '<a><b c="1">X</b><b c="2">Y</b></a>',
    -> 'a/b
    -> ) AS result;
+--------+
| result |
+--------+
| X Y    |
+--------+
1 row in set (0.03 sec)
```

In this case, the locator a/b resolves to /a/b.
Relative locators are also supported within predicates. In the following example, \( d[../@c="1"] \) is resolved as \( /a/b[@c="1"]/d \):

```sql
mysql> SELECT ExtractValue('...
    |<a>
    |   |<b c="1"><d>X</d></b>
    |   |<b c="2"><d>X</d></b>
    |   |<</a>',
    |   |  'a/b/d[../@c="1"]'
    |   | AS result;
>--------+
| result |
>--------+
| X      |
>--------+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.

- The `::` operator is not supported in combination with node types such as the following:
  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
  - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');
+-----------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b') |
| x                           |
+-----------------------------+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');
+-----------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*') |
| x y                         |
+-----------------------------+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).

- The following XPath functions are not supported, or have known issues as indicated:
  - `id()`
  - `lang()`
  - `local-name()`
XML Functions

- `name()`
- `namespace-uri()`
- `normalize-space()`
- `starts-with()`
- `string()`
- `substring-after()`
- `substring-before()`
- `translate()`

- The following axes are not supported:
  - `following-sibling`
  - `following`
  - `preceding-sibling`
  - `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```sql
mysql> SET @xml = '<a>111<b:c>222</d><e:f>444</e:f></b:c></a>);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----------------------------+
| ExtractValue(@xml, '//e:f') |
+-----------------------------+
| 444                         |
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>);
+--------------------------------------------+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |<g:h>555</g:h></b:c></a>                   |
+--------------------------------------------+<g:h>555</g:h></b:c></a>                   |
1 row in set (0.00 sec)

This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '/*a');
```
XML Functions

ERROR 1105 (HY000): XPATH syntax error: 'a'

If xml_frag does not consist of elements which are properly nested and closed, NULL is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '/a') |
| NULL                             |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)
```

```
SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)
```

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-------------------------------------+
| ExtractValue('<a>c</a><b/>', '/a') |
| c                                  |
+-------------------------------------+
1 row in set (0.00 sec)
```

**Important**

The replacement XML used as the third argument to `UpdateXML()` is not checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.** *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of an application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```php
<?php

$file = "users.xml";
$login = $POST["login"]; 
$password = $POST["password"]; 

$xpath = "/user[login/text()="$login" and password/text()="$password"]/attribute::id";

```
if( file_exists($file) )
{
    $xml = simplexml_load_file($file);

    if($result = $xml->xpath($xpath))
        echo "You are now logged in as user $result[0].";
    else
        echo "Invalid login name or password.";
} else
    exit("Failed to open $file.");
?>

No checks are performed on the input. This means that a malevolent user can "short-circuit" the test by entering ' or 1=1 for both the login name and password, resulting in $xpath being evaluated as shown here:

//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id

Since the expression inside the square brackets always evaluates as true, it is effectively the same as this one, which matches the id attribute of every user element in the XML document:

//user/attribute::id

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of $xpath, forcing the values passed from a Web form to be converted to strings:

$xpath = "//user[login/text()='$login' and password/text()='$password']/attribute::id";

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper Blind XPath Injection (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL ExtractValue() function:

cmsql> SELECT ExtractValue("load_file('users.xml'),
       //user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id" AS id;
+-------------------------------+
<table>
<thead>
<tr>
<th>id</th>
</tr>
</thead>
</table>
+-------------------------------+
Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```sql
mysql> SELECT @id = ExtractValue(
    -> LOAD_FILE('users.xml'),
    -> '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
    -> );
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT IF(
    -> INSTR(@id, ' ') = 0,
    -> @id,
    -> 'Unable to retrieve user ID'
    -> ) AS singleID;
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

### 12.12 Bit Functions and Operators

#### Table 12.16 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>BIT_COUNT()</code></td>
<td>Return the number of bits that are set</td>
</tr>
<tr>
<td><code>&amp;</code></td>

</tr>
<tr>
<td><code>&gt;&gt;</code></td>
<td>Right shift</td>
</tr>
</tbody>
</table>

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()` , `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions are described in Section 12.20.1, “Aggregate (GROUP BY) Function Descriptions”.) Prior to MySQL 8.0, bit functions and operators required `BIGINT` (64-bit integer) arguments and returned `BIGINT` values, so they had a maximum range of 64 bits. Non-`BIGINT` arguments were converted to `BIGINT` prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type, which enables them to take arguments and produce return
Bit Operations Prior to MySQL 8.0

values larger than 64 bits. Nonbinary string arguments are converted to BIGINT and processed as such, as before.

An implication of this change in behavior is that bit operations on binary string arguments might produce a different result in MySQL 8.0 than in 5.7. For information about how to prepare in MySQL 5.7 for potential incompatibilities between MySQL 5.7 and 8.0, see Bit Functions and Operators, in MySQL 5.7 Reference Manual.

• Bit Operations Prior to MySQL 8.0
• Bit Operations in MySQL 8.0
• Binary String Bit-Operation Examples
• Bitwise AND, OR, and XOR Operations
• Bitwise Complement and Shift Operations
• BIT_COUNT() Operations
• BIT_AND(), BIT_OR(), and BIT_XOR() Operations
• Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals
• Bit-Operation Incompatibilities with MySQL 5.7

Bit Operations Prior to MySQL 8.0

Bit operations prior to MySQL 8.0 handle only unsigned 64-bit integer argument and result values (that is, unsigned BIGINT values). Conversion of arguments of other types to BIGINT occurs as necessary. Examples:

• This statement operates on numeric literals, treated as unsigned 64-bit integers:

```
mysql> SELECT 127 | 128, 128 << 2, BIT_COUNT(15);
+-----------+----------+---------------+
| 127 | 128 | 128 << 2 | BIT_COUNT(15) |
+-----------+----------+---------------+
|       255 |      512 |             4 |
```

• This statement performs to-number conversions on the string arguments ("127" to 127, and so forth) before performing the same operations as the first statement and producing the same results:

```
mysql> SELECT '127' | '128', '128' << 2, BIT_COUNT('15');
+---------------+------------+-----------------+
| '127' | '128' | '128' << 2 | BIT_COUNT('15') |
+---------------+------------+-----------------+
|           255 |        512 |               4 |
```

• This statement uses hexadecimal literals for the bit-operation arguments. MySQL by default treats hexadecimal literals as binary strings, but in numeric context evaluates them as numbers (see Section 9.1.4, “Hexadecimal Literals”). Prior to MySQL 8.0, numeric context includes bit operations. Examples:

```
mysql> SELECT X'7F' | X'80', X'80' << 2, BIT_COUNT(X'0F');
|-----------------|-----------------|
```

1944
Handling of bit-value literals in bit operations is similar to hexadecimal literals (that is, as numbers).

### Bit Operations in MySQL 8.0

MySQL 8.0 extends bit operations to handle binary string arguments directly (without conversion) and produce binary string results. (Arguments that are not integers or binary strings are still converted to integers, as before.) This extension enhances bit operations in the following ways:

- Bit operations become possible on values longer than 64 bits.
- It is easier to perform bit operations on values that are more naturally represented as binary strings than as integers.

For example, consider UUID values and IPv6 addresses, which have human-readable text formats like this:

**UUID**: 6ccd780c-baba-1026-9564-5b8c656024db  
**IPv6**: fe80::219:d1ff:fe91:1a72

It is cumbersome to operate on text strings in those formats. An alternative is convert them to fixed-length binary strings without delimiters. `UUID_TO_BIN()` and `INET6_ATON()` each produce a value of data type `BINARY(16)`, a binary string 16 bytes (128 bits) long. The following statements illustrate this (`HEX()` is used to produce displayable values):

```
mysql> SELECT HEX(UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db'));
+----------------------------------------------------------+
| HEX(UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db')) |
| 6CCD780CBABA102695645B8C656024DB                         |
+----------------------------------------------------------+

mysql> SELECT HEX(INET6_ATON('fe80::219:d1ff:fe91:1a72'));
+---------------------------------------------+
| HEX(INET6_ATON('fe80::219:d1ff:fe91:1a72')) |
| FE8000000000000219D1FFFE911A72            |
+---------------------------------------------+
```

Those binary values are easily manipulable with bit operations to perform actions such as extracting the timestamp from UUID values, or extracting the network and host parts of IPv6 addresses. (For examples, see later in this discussion.)

Arguments that count as binary strings include column values, routine parameters, local variables, and user-defined variables that have a binary string type: `BINARY`, `VARBINARY`, or one of the `BLOB` types.

What about hexadecimal literals and bit literals? Recall that those are binary strings by default in MySQL, but numbers in numeric context. How are they handled for bit operations in MySQL 8.0? Does MySQL continue to evaluate them in numeric context, as is done prior to MySQL 8.0? Or do bit operations evaluate them as binary strings, now that binary strings can be handled “natively” without conversion?

Answer: It has been common to specify arguments to bit operations using hexadecimal literals or bit literals with the intent that they represent numbers, so MySQL continues to evaluate bit operations in numeric context when all bit arguments are hexadecimal or bit literals, for backward compatibility. If you require evaluation as binary strings instead, that is easily accomplished: Use the `_binary` introducer for at least one literal.
• These bit operations evaluate the hexadecimal literals and bit literals as integers:

```
mysql> SELECT X'40' | X'01', b'11110001' & b'01001111';
+---------------+---------------------------+
| X'40' | X'01' | b'11110001' & b'01001111' |
| 65 | 65 |
+---------------+---------------------------+
```

• These bit operations evaluate the hexadecimal literals and bit literals as binary strings, due to the `_binary` introducer:

```
mysql> SELECT _binary X'40' | X'01', b'11110001' & _binary b'01001111';
+-----------------------+-----------------------------------+
| _binary X'40' | X'01' | b'11110001' & _binary b'01001111' |
| A | A |
+-----------------------+-----------------------------------+
```

Although the bit operations in both statements produce a result with a numeric value of 65, the second statement operates in binary-string context, for which 65 is ASCII A.

In numeric evaluation context, permitted values of hexadecimal literal and bit literal arguments have a maximum of 64 bits, as do results. By contrast, in binary-string evaluation context, permitted arguments (and results) can exceed 64 bits:

```
mysql> SELECT _binary X'4040404040404040' | X'0102030405060708';
+---------------------------------------------------+
| _binary X'4040404040404040' | X'0102030405060708' |
| ABCDEFGH |
+---------------------------------------------------+
```

There are several ways to refer to a hexadecimal literal or bit literal in a bit operation to cause binary-string evaluation:

- `_binary literal`
- `BINARY literal`
- `CAST(literal AS BINARY)`

Another way to produce binary-string evaluation of hexadecimal literals or bit literals is to assign them to user-defined variables, which results in variables that have a binary string type:

```
mysql> SET @v1 = X'40', @v2 = X'01', @v3 = b'11110001', @v4 = b'01001111';
mysql> SELECT @v1 | @v2, @v3 & @v4;
+-----------+-----------+
| @v1 | @v2 | @v3 & @v4 |
| A         | A         |
+-----------+-----------+
```

In binary-string context, bitwise operation arguments must have the same length or an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs:

```
mysql> SELECT _binary X'40' | X'0001';
ERROR 3513 (HY000): Binary operands of bitwise operators must be of equal length
```
To satisfy the equal-length requirement, pad the shorter value with leading zero digits or, if the longer value begins with leading zero digits and a shorter result value is acceptable, strip them:

```sql
mysql> SELECT _binary X'0040' | X'0001';
+---------------------------+
| _binary X'0040' | X'0001' |
+---------------------------+
| A                        |
```

Padding or stripping can also be accomplished using functions such as `LPAD()`, `RPAD()`, `SUBSTR()`, or `CAST()`. In such cases, the expression arguments are no longer all literals and `_binary` becomes unnecessary. Examples:

```sql
mysql> SELECT LPAD(X'40', 2, X'00') | X'0001';
+---------------------------------+
| LPAD(X'40', 2, X'00') | X'0001' |
+---------------------------------+
|  A                              |
```

```sql
mysql> SELECT X'40' | SUBSTR(X'0001', 2, 1);
+-------------------------------+
| X'40' | SUBSTR(X'0001', 2, 1) |
+-------------------------------+
| A                             |
```

**Binary String Bit-Operation Examples**

The following example illustrates use of bit operations to extract parts of a UUID value, in this case, the timestamp and IEEE 802 node number. This technique requires bitmasks for each extracted part.

Convert the text UUID to the corresponding 16-byte binary value so that it can be manipulated using bit operations in binary-string context:

```sql
mysql> SET @uuid = UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db');
mysql> SELECT HEX(@uuid);
+----------------------------------+
| HEX(@uuid)                       |
+----------------------------------+
| 6CCD780CBABA102695645B8C656024DB |
```

Construct bitmasks for the timestamp and node number parts of the value. The timestamp comprises the first three parts (64 bits, bits 0 to 63) and the node number is the last part (48 bits, bits 80 to 127):

```sql
mysql> SET @ts_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16));
mysql> SET @node_mask = CAST(X'FFFFFFFFFFFFFF' AS BINARY(16)) >> 80;
mysql> SELECT HEX(@ts_mask);
+----------------------------------+
| HEX(@ts_mask)                    |
+----------------------------------+
| FFFFFFFFFFFFFFF0000000000000000 |
```
The `CAST(... AS BINARY(16))` function is used here because the masks must be the same length as the UUID value against which they are applied. The same result can be produced using other functions to pad the masks to the required length:

```sql
SET @ts_mask = RPAD(X'FFFFFFFFFFFFFFFF', 16, X'00');
SET @node_mask = LPAD(X'FFFFFFFFFFFF', 16, X'00');
```

Use the masks to extract the timestamp and node number parts:

```sql
mysql> SELECT HEX(@uuid & @ts_mask) AS 'timestamp part';
+----------------------------------+
| timestamp part                   |
| 6CCD780CBABA10260000000000000000 |
+----------------------------------+
mysql> SELECT HEX(@uuid & @node_mask) AS 'node part';
+----------------------------------+
| node part                        |
| 000000000000000000005B8C656024DB |
+----------------------------------+
```

The preceding example uses these bit operations: right shift (`>>`) and bitwise AND (`&`).

### Note

`UUID_TO_BIN()` takes a flag that causes some bit rearrangement in the resulting binary UUID value. If you use that flag, modify the extraction masks accordingly.

The next example uses bit operations to extract the network and host parts of an IPv6 address. Suppose that the network part has a length of 80 bits. Then the host part has a length of `128 - 80 = 48` bits. To extract the network and host parts of the address, convert it to a binary string, then use bit operations in binary-string context.

Convert the text IPv6 address to the corresponding binary string:

```sql
mysql> SET @ip = INET6_ATON('fe80::219:d1ff:fe91:1a72');
```

Define the network length in bits:

```sql
mysql> SET @net_len = 80;
```

Construct network and host masks by shifting the all-ones address left or right. To do this, begin with the address `::`, which is shorthand for all zeros, as you can see by converting it to a binary string like this:

```sql
mysql> SELECT HEX(INET6_ATON('::')) AS 'all zeros';
+----------------------------------+
| all zeros                        |
| 00000000000000000000000000000000 |
+----------------------------------+
```
To produce the complementary value (all ones), use the ~ operator to invert the bits:

```sql
mysql> SELECT HEX(~INET6_ATON('::')) AS 'all ones';
+----------------------------------+
| all ones                         |
| FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF |
+----------------------------------+
```

Shift the all-ones value left or right to produce the network and host masks:

```sql
mysql> SET @net_mask = ~INET6_ATON('::') << (128 - @net_len);
mysql> SET @host_mask = ~INET6_ATON('::') >> @net_len;
```

Display the masks to verify that they cover the correct parts of the address:

```sql
mysql> SELECT INET6_NTOA(@net_mask) AS 'network mask';
+----------------------------+
| network mask               |
| ffff:ffff:ffff:ffff:ffff:: |
+----------------------------+
mysql> SELECT INET6_NTOA(@host_mask) AS 'host mask';
+------------------------+
| host mask              |
| ::ffff:255.255.255.255 |
+------------------------+
```

Extract and display the network and host parts of the address:

```sql
mysql> SET @net_part = @ip & @net_mask;
mysql> SET @host_part = @ip & @host_mask;
mysql> SELECT INET6_NTOA(@net_part) AS 'network part';
+-----------------+
| network part    |
| fe80::219:0:0:0 |
+-----------------+
mysql> SELECT INET6_NTOA(@host_part) AS 'host part';
+------------------+
| host part        |
| ::d1ff:fe91:1a72 |
+------------------+
```

The preceding example uses these bit operations: Complement (~), left shift (<<), and bitwise AND (&).

The remaining discussion provides details on argument handling for each group of bit operations, more information about literal-value handling in bit operations, and potential incompatibilities between MySQL 8.0 and older MySQL versions.

**Bitwise AND, OR, and XOR Operations**

For &, |, and ~ bit operations, the result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
Bitwise Complement and Shift Operations

- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

Examples of numeric evaluation:

```
mysql> SELECT 64 | 1, X'40' | X'01';
+--------+---------------+
| 64     | 1             |
| X'40'  | X'01'         |
| 65     | 65            |
+--------+---------------+
```

Examples of binary-string evaluation:

```
mysql> SELECT _binary X'40' | X'01';
+-----------------------+
| _binary X'40' | X'01' |
| A             |
+-----------------------+
mysql> SET @var1 = X'40', @var2 = X'01';
mysql> SELECT @var1 | @var2;
+---------------+
| @var1 | @var2 |
| A     |
+---------------+
```

Bitwise Complement and Shift Operations

For ~, <<, and >> bit operations, the result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For shift operations, bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

Examples of numeric evaluation:

```
mysql> SELECT ~0, 64 << 2, X'40' << 2;
+----------------------+---------+------------+
| ~0                   | 64 << 2 | X'40' << 2 |
| 18446744073709551615 |     256 |        256 |
+----------------------+---------+------------+
```

Examples of binary-string evaluation:

```
mysql> SELECT HEX(_binary X'1111000022220000' >> 16);
+----------------------------------------+
| HEX(_binary X'1111000022220000' >> 16) |
```
BIT_COUNT() Operations

The `BIT_COUNT()` function always returns an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```
mysql> CREATE TABLE t (group_id INT, a VARBINARY(6));
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (2, NULL);
mysql> INSERT INTO t VALUES (2, X'1234');
mysql> INSERT INTO t VALUES (2, X'FF34');
```

BIT_AND(), BIT_OR(), and BIT_XOR() Operations

For the `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` bit functions, the result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the length of the argument values (all bits 1 for `BIT_AND()`, all bits 0 for `BIT_OR()`, and `BIT_XOR()`).

Example:
Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

For backward compatibility, MySQL 8.0 evaluates bit operations in numeric context when all bit arguments are hexadecimal literals, bit literals, or NULL literals. That is, bit operations on binary-string bit arguments do not use binary-string evaluation if all bit arguments are unadorned hexadecimal literals, bit literals, or NULL literals. (This does not apply to such literals if they are written with a **_binary** introducer, **BINARY** operator, or other way of specifying them explicitly as binary strings.)

The literal handling just described is the same as prior to MySQL 8.0. Examples:

- These bit operations evaluate the literals in numeric context and produce a **BIGINT** result:
  ```
  b'0001' | b'0010'
  X'0008' << 8
  ```

- These bit operations evaluate **NULL** in numeric context and produce a **BIGINT** result that has a **NULL** value:
  ```
  NULL & NULL
  NULL >> 4
  ```

In MySQL 8.0, you can cause those operations to evaluate the arguments in binary-string context by indicating explicitly that at least one argument is a binary string:

```
_binary b'0001' | b'0010'
_binary X'0008' << 8
BINARY NULL & NULL
BINARY NULL >> 4
```

The result of the last two expressions is **NULL**, just as without the **BINARY** operator, but the data type of the result is a binary string type rather than an integer type.

**Bit-Operation Incompatibilities with MySQL 5.7**

Because bit operations can handle binary string arguments natively in MySQL 8.0, some expressions produce a different result in MySQL 8.0 than in 5.7. The five problematic expression types to watch out for are:

```
nonliteral_binary { & | ^ } binary
binary { & | ^ } nonliteral_binary
nonliteral_binary { << >> } anything
~ nonliteral_binary
AGGR_BIT_FUNC(nonliteral_binary)
```

Those expressions return **BIGINT** in MySQL 5.7, binary string in 8.0.

Explanation of notation:

- `{ op1 op2 ... }`: List of operators that apply to the given expression type.
- **binary**: Any kind of binary string argument, including a hexadecimal literal, bit literal, or `NULL` literal.
- **nonliteral_binary**: An argument that is a binary string value other than a hexadecimal literal, bit literal, or `NULL` literal.
- **AGGR_BIT_FUNC**: An aggregate function that takes bit-value arguments: `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`.

For information about how to prepare in MySQL 5.7 for potential incompatibilities between MySQL 5.7 and 8.0, see Bit Functions and Operators, in MySQL 5.7 Reference Manual.

The following list describes available bit functions and operators:

- **|**

  Bitwise OR.

  The result type depends on whether the arguments are evaluated as binary strings or numbers:

  - Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

  - Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  For more information, see the introductory discussion in this section.

  ```
  mysql> SELECT 29 | 15;
  -> 31
  mysql> SELECT _binary X'40404040' | X'01020304';
  -> 'ABCD'
  ```

- **&**

  Bitwise AND.

  The result type depends on whether the arguments are evaluated as binary strings or numbers:

  - Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

  - Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

  For more information, see the introductory discussion in this section.

  ```
  mysql> SELECT 29 & 15;
  -> 13
  mysql> SELECT HEX(_binary X'FF' & b'11110000');
  -> 'F0'
  ```

- **^**

  Bitwise XOR.
The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
mysql> SELECT HEX(_binary X'FEDC' ^ X'1111');
-> 'EFCD'
```

- `<<`

  Shifts a longlong (BIGINT) number or binary string to the left.

  The result type depends on whether the bit argument is evaluated as a binary string or number:

  - Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

  - Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

  Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

  For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 << 2;
-> 4
mysql> SELECT HEX(_binary X'00FF00FF00FF' << 8);
-> 'FF00FF00FF00'
```

- `>>`

  Shifts a longlong (BIGINT) number or binary string to the right.

  The result type depends on whether the bit argument is evaluated as a binary string or number:

  - Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.

  - Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.
Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 4 >> 2;
-> 1
mysql> SELECT HEX(_binary X'00FF00FF00FF' >> 8);
-> '0000FF00FF00'
```

• `~`

Invert all bits.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 5 & ~1;
-> 4
mysql> SELECT HEX(~X'0000FFFF1111EEEE');
-> 'FFFF0000EEEE1111'
```

• `BIT_COUNT(N)`

Returns the number of bits that are set in the argument `N` as an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```
mysql> SELECT BIT_COUNT(64), BIT_COUNT(BINARY 64);
-> 1, 7
mysql> SELECT BIT_COUNT('64'), BIT_COUNT(_binary '64');
-> 1, 7
mysql> SELECT BIT_COUNT(X'40'), BIT_COUNT(_binary X'40');
-> 1, 1
```

### 12.13 Encryption and Compression Functions

**Table 12.17 Encryption Functions**

<table>
<thead>
<tr>
<th>Name</th>

<tr>
<td>ASYMMETRIC_SIGN()</td>
<td>Generate signature from digest</td>
</tr>
</tbody>
</table>
Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `SHA()`, `SHA1()`, `SHA2()`, `STATEMENT_DIGEST()`, `STATEMENT_DIGEST_TEXT()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is `binary`.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);

To convert hex strings to more compact form, modify the application to use UNHEX() and BINARY(16) instead as follows:

CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

**Note**

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as SHA2().

**Caution**

Passwords or other sensitive values supplied as arguments to encryption functions are sent in cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- **AES_DECRYPT(crypt_str, key_str[, init_vector])**

  This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of AES_ENCRYPT().

  The optional initialization vector argument, init_vector. Statements that use AES_DECRYPT() are unsafe for statement-based replication.

- **AES_ENCRYPT(str, key_str[, init_vector])**

  AES_ENCRYPT() and AES_DECRYPT() implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

  AES_ENCRYPT() encrypts the string str using the key string key_str and returns a binary string containing the encrypted output. AES_DECRYPT() decrypts the encrypted string crypt_str using the key string key_str and returns the original cleartext string. If either function argument is NULL, the function returns NULL.

  The str and crypt_str arguments can be any length, and padding is automatically added to str so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the AES_DECRYPT() function. The length of crypt_str can be calculated using this formula:

  $$16 \times (\text{trunc}(\text{string\_length} \div 16) + 1)$$
For a key length of 128 bits, the most secure way to pass a key to the `key_str` argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```sql
INSERT INTO t
VALUES (1, AES_ENCRYPT('text', UNHEX('F329A0B371ED29441B839D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```sql
INSERT INTO t
VALUES (1, AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

Do not pass a password or passphrase directly to `crypt_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

`AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode and take an optional `init_vector` initialization vector argument:

- The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see Section 5.1.8, "Server System Variables".

- The optional `init_vector` argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional `init_vector` argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing.

For modes that do not require `init_vector`, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`. For encryption modes that require an initialization vector, the same vector must be used for encryption and decryption.

```sql
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT AES_DECRYPT(@crypt_str,@key_str,@init_vector);
<table>
<thead>
<tr>
<th>AES_DECRYPT(@crypt_str,@key_str,@init_vector)</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
</tr>
</tbody>
</table>
```

The following table lists each permitted block encryption mode, the SSL libraries that support it, and whether the initialization vector argument is required.

<table>
<thead>
<tr>
<th>Block Encryption Mode</th>
<th>SSL Libraries that Support Mode</th>
<th>Initialization Vector Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECB</td>
<td>OpenSSL, wolfSSL</td>
<td>No</td>
</tr>
</tbody>
</table>
## Encryption and Compression Functions

<table>
<thead>
<tr>
<th>Block Encryption Mode</th>
<th>SSL Libraries that Support Mode</th>
<th>Initialization Vector Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>CBC</td>
<td>OpenSSL, wolfSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB1</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB8</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB128</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>OFB</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication.

- **COMPRESS(string_to_compress)**

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as *zlib*. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```sql
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000))); -> 21
mysql> SELECT LENGTH(COMPRESS('')); -> 0
mysql> SELECT LENGTH(COMPRESS('a')); -> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16))); -> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `. character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)

- **DECODE(crypt_str,pass_str)**

This function was removed in MySQL 8.0.3.

Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- **DES_DECRYPT(crypt_str[,key_str])**

This function was removed in MySQL 8.0.3.

Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- **DES_ENCRYPT(str[,key_num|key_str])**

This function was removed in MySQL 8.0.3.

Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- **ENCODE(str,pass_str)**

This function was removed in MySQL 8.0.3.
Encryption and Compression Functions

Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- `ENCRYPT(str[,salt])`
  
  This function was removed in MySQL 8.0.3. For one-way hashing, consider using `SHA2()` instead.

- `MD5(str)`

  Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

  The return value is a string in the connection character set.

  If FIPS mode is enabled, `MD5()` returns `NULL`. See Section 6.6, “FIPS Support”.

  ```
  mysql> SELECT MD5('testing');
  -> 'ae2b1fca515949e5d54fb22b8ed95575'
  ```

  This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

  See the note regarding the MD5 algorithm at the beginning this section.

- `PASSWORD(str)`

  This function was removed in MySQL 8.0.11.

- `RANDOM_BYTES(len)`

  This function returns a binary string of `len` random bytes generated using the random number generator of the SSL library. Permitted values of `len` range from 1 to 1024. For values outside that range, `RANDOM_BYTES()` generates a warning and returns `NULL`.

  `RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, `len` must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

  `RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

- `SHA1(str), SHA(str)`

  Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. `SHA()` is synonymous with `SHA1()`.

  The return value is a string in the connection character set.

  ```
  mysql> SELECT SHA1('abc');
  -> 'a9993e3647068116aba3e25717850c26c9cd0d89d'
  ```

  `SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)`
Encryption and Compression Functions

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the cleartext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is NULL or the hash length is not one of the permitted values, the return value is NULL. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d822862a477bda255b32aadbe4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 6.4, “Using Encrypted Connections”.

SHA2() can be considered cryptographically more secure than MD5() or SHA1().

• STATEMENT_DIGEST(statement)

Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or NULL if the argument is NULL. The related STATEMENT_DIGEST_TEXT() function returns the normalized statement digest. For information about statement digesting, see Section 26.10, “Performance Schema Statement Digests and Sampling”.

Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

The max_digest_length system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```sql
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+------------------------------------------------------------------+
| STATEMENT_DIGEST(@stmt)                                          |
+------------------------------------------------------------------+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492c9d78387 |
+------------------------------------------------------------------+
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+----------------------------------------------------------+
| STATEMENT_DIGEST_TEXT(@stmt)                             |
+----------------------------------------------------------+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ?  |
+----------------------------------------------------------+
```

• STATEMENT_DIGEST_TEXT(statement)

Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or NULL if the argument is NULL. For additional discussion and examples, see the description of the related STATEMENT_DIGEST() function.

• UNCOMPRESS(string_to_uncompress)

Uncompresses a string compressed by the COMPRESS() function. If the argument is not a compressed value, the result is NULL. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL.
12.14 Locking Functions

This section describes functions used to manipulate user-level locks.

Table 12.18 Locking Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>
<td>Release all current named locks</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

- GET_LOCK(str, timeout)

---

### Locking Functions

- **UNCOMPRESSED_LENGTH(compressed_string)**

  Returns the length that the compressed string had before being compressed.

- **VALIDATE_PASSWORD_STRENGTH(str)**

  Given an argument representing a cleartext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

  Password assessment by VALIDATE_PASSWORD_STRENGTH() is done by the validate_password component. If that component is not installed, the function always returns 0. For information about installing validate_password, see Section 6.5.3, "The Password Validation Component". To examine or configure the parameters that affect password testing, check or set the system variables implemented by validate_password. See Section 6.5.3.2, “Password Validation Options and Variables”.

  The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the validate_password.check_user_name system variable is enabled and the password matches the user name, VALIDATE_PASSWORD_STRENGTH() returns 0 regardless of how other validate_password system variables are set.

<table>
<thead>
<tr>
<th>Password Test</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length &lt; 4</td>
<td>0</td>
</tr>
<tr>
<td>Length ≥ 4 and &lt; validate_password.length</td>
<td>25</td>
</tr>
<tr>
<td>Satisfies policy 1 (LOW)</td>
<td>50</td>
</tr>
<tr>
<td>Satisfies policy 2 (MEDIUM)</td>
<td>75</td>
</tr>
<tr>
<td>Satisfies policy 3 (STRONG)</td>
<td>100</td>
</tr>
</tbody>
</table>

---

```sql
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
    -> 'any string'
mysql> SELECT UNCOMPRESS('any string');
    -> NULL
```

```sql
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
    -> 30
```

---

### Chapter 12.14 Locking Functions

This section describes functions used to manipulate user-level locks.

Table 12.18 Locking Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>
<td>Release all current named locks</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

- GET_LOCK(str, timeout)
Locking Functions

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. For example, suppose that you execute these statements:

```sql
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success).

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

Uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER LEVEL LOCK` and the `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

MySQL enforces a maximum length on lock names of 64 characters.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. 
Caution

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see Section 29.3.1, “The Locking Service”.

- **IS_FREE_LOCK(str)**

  Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_USED_LOCK(str)**

  Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_ALL_LOCKS()**

  Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_LOCK(str)**

  Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

  The **DO** statement is convenient to use with `RELEASE_LOCK()`. See Section 13.2.3, “DO Syntax”.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.
12.15 Information Functions

Table 12.19 Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BENCHMARK()</td>
<td>Repeatedly execute an expression</td>
</tr>
<tr>
<td>CHARSET()</td>
<td>Return the character set of the argument</td>
</tr>
<tr>

<td>Synonym for USER()</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>

- **BENCHMARK**(count, expr)

The BENCHMARK() function executes the expression expr repeatedly count times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the mysql client, which reports query execution times:

```sql
mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));
+-------------------------+
| BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
| 0                      |
+-------------------------+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute BENCHMARK() several times, and to interpret the result with regard to how heavily loaded the server machine is.

BENCHMARK() is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:
Information Functions

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.

- Executing a `SELECT expr` statement \(N\) times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation \(N\) times each. The latter involves only runtime evaluation \(N\) times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'utf8'
mysql> SELECT CHARSET(CONVERT('abc' USING latin1));
-> 'latin1'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE utf8_swedish_ci);
  -> 0
mysql> SELECT COERCIBILITY(USER());
  -> 3
mysql> SELECT COERCIBILITY('abc');
  -> 4
mysql> SELECT COERCIBILITY(1000);
  -> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with <code>COLLATE</code> clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td><code>USER()</code> return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Numeric</td>
<td>Numeric or temporal value</td>
</tr>
<tr>
<td>5</td>
<td>Ignorable</td>
<td><code>NULL</code> or an expression derived from <code>NULL</code></td>
</tr>
</tbody>
</table>
For more information, see Section 10.8.4, “Collation Coercibility in Expressions”.

• **COLLATION**(str)

Returns the collation of the string argument.

```sql
mysql> SELECT COLLATION('abc');
-> 'utf8_general_ci'

mysql> SELECT COLLATION(_utf8mb4'abc');
-> 'utf8mb4_0900_ai_ci'

mysql> SELECT COLLATION(_latin1'abc');
-> 'latin1_swedish_ci'
```

• **CONNECTION_ID()**

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the ID column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the Id column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```sql
mysql> SELECT CONNECTION_ID();
-> 23786
```

• **CURRENT_ROLE()**

Returns a utf8 string containing the current active roles for the current session, separated by commas, or NONE if there are none. The value reflects the setting of the `sql_quote_show_create` system variable.

Suppose that an account is granted roles as follows:

```sql
GRANT 'r1', 'r2' TO 'u1'@'localhost';
SET DEFAULT ROLE ALL TO 'u1'@'localhost';
```

In sessions for u1, the initial `CURRENT_ROLE()` value names the default account roles. Using `SET ROLE` changes that:

```sql
mysql> SELECT CURRENT_ROLE();
+-------------------+
| CURRENT_ROLE()    |
+-------------------+
| `r1`@`%`,`r2`@`%` |
+-------------------+

mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| `r1`@`%`       |
+----------------+
```

• **CURRENT_USER, CURRENT_USER()**

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the utf8 character set.
The value of `CURRENT_USER()` can differ from the value of `USER()`.

```plaintext
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see Section 17.4.1.8, “Replication of `CURRENT_USER()`”.
Information Functions

Returns the default (current) database name as a string in the utf8 character set. If there is no default database, DATABASE() returns NULL. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```sql
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, DATABASE() returns NULL.

- FOUND_ROWS()

A SELECT statement may include a LIMIT clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the LIMIT, but without running the statement again. To obtain this row count, include an SQL_CALC_FOUND_ROWS option in the SELECT statement, and then invoke FOUND_ROWS() afterward:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
    ... WHERE id > 100 LIMIT 10;
```

The second SELECT returns a number indicating how many rows the first SELECT would have returned had it been written without the LIMIT clause.

In the absence of the SQL_CALC_FOUND_ROWS option in the most recent successful SELECT statement, FOUND_ROWS() returns the number of rows in the result set returned by that statement. If the statement includes a LIMIT clause, FOUND_ROWS() returns the number of rows up to the limit. For example, FOUND_ROWS() returns 10 or 60, respectively, if the statement includes LIMIT 10 or LIMIT 50, 10.

The row count available through FOUND_ROWS() is transient and not intended to be available past the statement following the SELECT SQL_CALC_FOUND_ROWS statement. If you need to refer to the value later, save it:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using SELECT SQL_CALC_FOUND_ROWS, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without LIMIT, because the result set need not be sent to the client.

SQL_CALC_FOUND_ROWS and FOUND_ROWS() can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using FOUND_ROWS() enables you to determine how many other pages are needed for the rest of the result.

The use of SQL_CALC_FOUND_ROWS and FOUND_ROWS() is more complex for UNION statements than for simple SELECT statements, because LIMIT may occur at multiple places in a UNION. It may be applied to individual SELECT statements in the UNION, or global to the UNION result as a whole.

The intent of SQL_CALC_FOUND_ROWS for UNION is that it should return the row count that would be returned without a global LIMIT. The conditions for use of SQL_CALC_FOUND_ROWS with UNION are:

- The SQL_CALC_FOUND_ROWS keyword must appear in the first SELECT of the UNION.
Information Functions

• The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.

• If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

• `ICU_VERSION()`

The version of the International Components for Unicode (ICU) library used to support regular expression operations (see Section 12.5.2, “Regular Expressions”). This function is primarily intended for use in test cases.

• `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```sql
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

• If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
• For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first *AUTO_INCREMENT* value generated for most recent statement affecting an *AUTO_INCREMENT* column *by that client*. This value cannot be affected by other clients, even if they generate *AUTO_INCREMENT* values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the *AUTO_INCREMENT* column of a row to a non-“magic” value (that is, a value that is not *NULL* and not 0).

---

**Important**

If you insert multiple rows using a single *INSERT* statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same *INSERT* statement against some other server.

For example:

```
mysql> USE test;
mysql> CREATE TABLE t (  
    id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    name VARCHAR(10) NOT NULL  
);  
mysql> INSERT INTO t VALUES (NULL, 'Bob');  
mysql> SELECT * FROM t;  
+----+------+  
| id | name |  
| 1 | Bob  |  
+----+------+  
mysql> SELECT LAST_INSERT_ID();  
+------------------+  
| LAST_INSERT_ID() |  
+------------------+  
mysql> INSERT INTO t VALUES  
    (NULL, 'Mary'),  
    (NULL, 'Jane'),  
    (NULL, 'Lisa');  
mysql> SELECT * FROM t;  
+----+------+  
| id | name |  
| 1 | Bob  |  
| 2 | Mary |  
| 3 | Jane |  
| 4 | Lisa |  
+----+------+  
mysql> SELECT LAST_INSERT_ID();  
+------------------+  
| LAST_INSERT_ID() |  
+------------------+  
```
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to `1` or `2`, as demonstrated in the following example:

```
mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+------------------+
| @@innodb_autoinc_lock_mode |
+------------------+
| 1                 |
+------------------+

mysql> CREATE TABLE `t` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `val` INT(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

# Insert two rows

mysql> INSERT INTO t (val) VALUES (1),(2);

# With auto_increment_offset=1, the inserted rows
# result in an AUTO_INCREMENT value of 3

mysql> SHOW CREATE TABLE t;
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1

# LAST_INSERT_ID() returns the first automatically generated
# value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1                |
+------------------+

# The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0
```

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
Information Functions

# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
 Table: t
Create Table: CREATE TABLE `t` (  `id` int(11) NOT NULL AUTO_INCREMENT,  `val` int(11) DEFAULT NULL,  PRIMARY KEY (`id`),  UNIQUE KEY `i1` (`val`) ) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

For more information, see Section 15.6.1.4, “AUTO_INCREMENT Handling in InnoDB”.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

    mysql> CREATE TABLE sequence (id INT NOT NULL);
    mysql> INSERT INTO sequence VALUES (0);

2. Use the table to generate sequence numbers like this:

    mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
    mysql> SELECT LAST_INSERT_ID();

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See Section 28.7.7.38, “mysql_insert_id()”.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- **ROLES_GRAPHML()**

Returns a `utf8` string containing a GraphML document representing memory role subgraphs. The `ROLE_ADMIN` or `SUPER` privilege is required to see content in the `<graphml>` element. Otherwise, the result shows only an empty element:
• **ROW_COUNT()**

**ROW_COUNT()** returns a value as follows:

- **DDL statements**: 0. This applies to statements such as **CREATE TABLE** or **DROP TABLE**.
- **DML statements other than SELECT**: The number of affected rows. This applies to statements such as **UPDATE**, **INSERT**, or **DELETE** (as before), but now also to statements such as **ALTER TABLE** and **LOAD DATA**.
- **SELECT**: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for **SELECT * FROM t1, ROW_COUNT()** returns -1. For **SELECT * FROM t1 INTO OUTFILE 'file_name'**, **ROW_COUNT()** returns the number of rows written to the file.
- **SIGNAL** statements: 0.

For **UPDATE** statements, the affected-rows value by default is the number of rows actually changed. If you specify the **CLIENT_FOUND_ROWS** flag to **mysql_real_connect()** when connecting to **mysqld**, the affected-rows value is the number of rows “found”; that is, matched by the **WHERE** clause.

For **REPLACE** statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For **INSERT ... ON DUPLICATE KEY UPDATE** statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the **CLIENT_FOUND_ROWS** flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The **ROW_COUNT()** value is similar to the value from the **mysql_affected_rows()** C API function and the row count that the **mysql** client displays following statement execution.
Important

ROW_COUNT() is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- **SCHEMA()**
  This function is a synonym for DATABASE().

- **SESSION_USER()**
  SESSION_USER() is a synonym for USER().

- **SYSTEM_USER()**
  SYSTEM_USER() is a synonym for USER().

- **USER()**
  Returns the current MySQL user name and host name as a string in the utf8 character set.

  ```
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of CURRENT_USER().

- **VERSION()**
  Returns a string that indicates the MySQL server version. The string uses the utf8 character set. The value might have a suffix in addition to the version number. See the description of the version system variable in Section 5.1.8, “Server System Variables”.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

```
mysql> SELECT VERSION();
-> '8.0.17-standard'
```  

### 12.16 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.5, “Spatial Data Types”.
12.16.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GeomCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>MBRCoveredBy()</td>
<td>Whether one MBR is covered by another</td>
</tr>
<tr>
<td>MBRCovers()</td>
<td>Whether one MBR covers another</td>
</tr>
<tr>
<td>MBRDisjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>MBREquals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td>ST_Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>ST_AsBinary(),ST_AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>ST_AsGeoJSON()</td>
<td>Generate GeoJSON object from geometry</td>
</tr>
<tr>
<td>ST_AsText(),ST_AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>ST_Buffer()</td>
<td>Return geometry of points within given distance from</td>
</tr>
<tr>
<td></td>
<td>geometry</td>
</tr>
<tr>
<td>ST_Buffer_Strategy()</td>
<td>Produce strategy option for ST_Buffer()</td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>ST_Contains()</td>
<td>Whether one geometry contains another</td>
</tr>
<tr>
<td>ST_ConvexHull()</td>
<td>Return convex hull of geometry</td>
</tr>
<tr>
<td>ST_Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>ST_Difference()</td>
<td>Return point set difference of two geometries</td>
</tr>
<tr>
<td>ST_Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>ST_Disjoint()</td>
<td>Whether one geometry is disjoint from another</td>
</tr>
<tr>
<td>ST_Distance()</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>ST_Distance_Sphere()</td>
<td>Minimum distance on earth between two geometries</td>
</tr>
<tr>
<td>ST_EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>ST_Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ST_Equals()</td>
<td>Whether one geometry is equal to another</td>
</tr>
<tr>
<td>ST_ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>ST_GeoHash()</td>
<td>Produce a geohash value</td>
</tr>
<tr>
<td>ST_GeomCollFromText(), ST_GeometryCollectionFromText(), ST_GeomCollFromText()</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB()</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>ST_GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>ST_GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>ST_GeomFromGeoJSON()</td>
<td>Generate geometry from GeoJSON object</td>
</tr>
<tr>
<td>ST_GeomFromText(), ST_GeometryFromText()</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>ST_GeomFromWKB(), ST_GeometryFromWKB()</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>ST_InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>ST_Intersection()</td>
<td>Return point set intersection of two geometries</td>
</tr>
<tr>
<td>ST_Intersects()</td>
<td>Whether one geometry intersects another</td>
</tr>
<tr>
<td>ST_IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>ST_IsEmpty()</td>
<td>Placeholder function</td>
</tr>
<tr>
<td>ST_IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>ST_IsValid()</td>
<td>Whether a geometry is valid</td>
</tr>
<tr>
<td>ST_LatFromGeoHash()</td>
<td>Return latitude from geohash value</td>
</tr>
<tr>
<td>ST_Latitude()</td>
<td>Return latitude of Point</td>
</tr>
<tr>
<td>ST_Length()</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>ST_LineFromText(), ST_LineStringFromText()</td>
<td>Construct LineString from WKT</td>
</tr>
<tr>
<td>ST_LineFromWKB(), ST_LineStringFromWKB()</td>
<td>Construct LineString from WKB</td>
</tr>
<tr>
<td>ST_LongFromGeoHash()</td>
<td>Return longitude from geohash value</td>
</tr>
<tr>
<td>ST_Longitude()</td>
<td>Return longitude of Point</td>
</tr>
<tr>
<td>ST_MakeEnvelope()</td>
<td>Rectangle around two points</td>
</tr>
<tr>
<td>ST_MLineFromText(), ST_MultiLineStringFromText()</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>ST_MLineFromWKB(), ST_MultiLineStringFromWKB()</td>
<td>Construct MultiLineString from WKB</td>
</tr>
<tr>
<td>ST_MPointFromText(), ST_MultiPointFromText()</td>
<td>Construct MultiPoint from WKT</td>
</tr>
<tr>
<td>ST_MPointFromWKB(), ST_MultiPointFromWKB()</td>
<td>Construct MultiPoint from WKB</td>
</tr>
</tbody>
</table>
12.16.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described at Section 11.5.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional argument-handling characteristics, as discussed in the sections where those function descriptions occur.

Spatial functions are defined only for valid geometry values.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.
SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

Spatial functions that take multiple geometry arguments require those arguments to have the same SRID value (that is, same value in the lower 32 bits). Assuming equal SRIDs, spatial functions do nothing with them after performing the equality check; geometry values are implicitly handled using Cartesian coordinates (SRID 0). If a spatial function returns ER_GIS_DIFFERENT_SRIDS, it means that the geometry arguments did not all have the same SRID. You must modify them to have the same SRID.

The Open Geospatial Consortium guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

Empty geometry-collection handling is as follows: An empty WKT input geometry collection may be specified as 'GEOMETRYCOLLECTION()'. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

**12.16.3 Functions That Create Geometry Values from WKT Values**

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see Well-Known Text (WKT) Format.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

`ST_GeomFromText()` accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

- `ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')`
- `ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')`

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Functions such as `ST_AsWKT()` that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+--------------------------+--------------------------+
| ST_AsWKT(@s1)            | ST_AsWKT(@s2)            |
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+--------------------------+--------------------------+
```
Unless otherwise specified, functions in this section handle their arguments as follows:

- If any geometry argument is \texttt{NULL} or is not a syntactically well-formed geometry, or if the SRID argument is \texttt{NULL}, the return value is \texttt{NULL}.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional \texttt{options} argument may be given to override the default axis order. \texttt{options} consists of a list of comma-separated \texttt{key=value}. The only permitted \texttt{key} value is \texttt{axis-order}, with permitted values of \texttt{lat-long}, \texttt{long-lat} and \texttt{srid-defined} (the default).

  If the \texttt{options} argument is \texttt{NULL}, the return value is \texttt{NULL}. If the \texttt{options} argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an \texttt{ER_SRS_NOT_FOUND} error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an \texttt{ER_LONGITUDE_OUT_OF_RANGE} error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an \texttt{ER_LATITUDE_OUT_OF_RANGE} error occurs.

  Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

- \texttt{ST_GeomCollFromText(wkt[, srid [, options]])}, \texttt{ST_GeometryCollectionFromText(wkt[, srid [, options]])}, \texttt{ST_GeomCollFromTxt(wkt[, srid [, options]])}

  Constructs a \texttt{GeometryCollection} value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10))";
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+--------------------------------------------+
| ST_AsText(ST_GeomCollFromText(@g))         |
+--------------------------------------------+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+--------------------------------------------+
```

- \texttt{ST_GeomFromText(wkt[, srid [, options]])}, \texttt{ST_GeometryFromText(wkt[, srid [, options]])}

  Constructs a geometry value of any type using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- \texttt{ST_LineFromText(wkt[, srid [, options]])}, \texttt{ST_LineStringFromText(wkt[, srid [, options]])}

  Constructs a \texttt{LineString} value using its WKT representation and SRID.

  These functions handle their arguments as described in the introduction to this section.
• **ST_MLineFromText**\( (\text{wkt}, \text{srid}, \text{options}) \), **ST_MultiLineStringFromText**\( (\text{wkt}, \text{srid}, \text{options}) \)

Constructs a **MultiLineString** value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• **ST_MPointFromText**\( (\text{wkt}, \text{srid}, \text{options}) \), **ST_MultiPointFromText**\( (\text{wkt}, \text{srid}, \text{options}) \)

Constructs a **MultiPoint** value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• **ST_MPolyFromText**\( (\text{wkt}, \text{srid}, \text{options}) \), **ST_MultiPolygonFromText**\( (\text{wkt}, \text{srid}, \text{options}) \)

Constructs a **MultiPolygon** value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• **ST_PointFromText**\( (\text{wkt}, \text{srid}, \text{options}) \)

Constructs a **Point** value using its WKT representation and SRID.

**ST_PointFromText**() handles its arguments as described in the introduction to this section.

• **ST_PolyFromText**\( (\text{wkt}, \text{srid}, \text{options}) \), **ST_PolygonFromText**\( (\text{wkt}, \text{srid}, \text{options}) \)

Constructs a **Polygon** value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

### 12.16.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a **BLOB** containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see [Well-Known Binary (WKB) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

**ST_GeomFromWKB**() accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 8.0, these functions also accepted geometry objects as returned by the functions in Section 12.16.5, “MySQL-Specific Functions That Create Geometry Values”. Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

- Rewrite constructs such as **ST_GeomFromWKB**\( (\text{Point}(0, 0)) \) as **Point**\( (0, 0) \).

- Rewrite constructs such as **ST_GeomFromWKB**\( (\text{Point}(0, 0), 4326), \text{Point}(0, 0), 4326) \) as **ST_SRID**\( (\text{Point}(0, 0), 4326), \text{Point}(0, 0), 4326) \) or **ST_GeomFromWKB**\( (\text{ST_AsWKB}(\text{Point}(0, 0)), 4326) \).

Unless otherwise specified, functions in this section handle their arguments as follows:

- If the WKB or SRID argument is **NULL**, the return value is **NULL**.
Functions That Create Geometry Values from WKB Values

• By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional \texttt{options} argument may be given to override the default axis order. \texttt{options} consists of a list of comma-separated \texttt{key} = \texttt{value}. The only permitted \texttt{key} value is \texttt{axis-order}, with permitted values of \texttt{lat-long}, \texttt{long-lat} and \texttt{srid-defined} (the default).

  If the \texttt{options} argument is \texttt{NULL}, the return value is \texttt{NULL}. If the \texttt{options} argument is invalid, an error occurs to indicate why.

• If an SRID argument refers to an undefined spatial reference system (SRS), an \texttt{ER_SRS_NOT_FOUND} error occurs.

• For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  • If a longitude value is not in the range \((-180, 180]\), an \texttt{ER_LONGITUDE_OUT_OF_RANGE} error occurs.
  • If a latitude value is not in the range \([-90, 90]\], an \texttt{ER_LATITUDE_OUT_OF_RANGE} error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

• \texttt{ST_GeomCollFromWKB(wkb[, srid [, options]])}, \texttt{ST_GeometryCollectionFromWKB(wkb[, srid [, options]])}

  Constructs a \texttt{GeometryCollection} value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• \texttt{ST_GeomFromWKB(wkb[, srid [, options]])}, \texttt{ST_GeometryFromWKB(wkb[, srid [, options]])}

  Constructs a geometry value of any type using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• \texttt{ST_LineFromWKB(wkb[, srid [, options]])}, \texttt{ST_LineStringFromWKB(wkb[, srid [, options]])}

  Constructs a \texttt{LineString} value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• \texttt{ST_MLineFromWKB(wkb[, srid [, options]])}, \texttt{ST_MultiLineStringFromWKB(wkb[, srid [, options]])}

  Constructs a \texttt{MultiLineString} value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

• \texttt{ST_MPointFromWKB(wkb[, srid [, options]])}, \texttt{ST_MultiPointFromWKB(wkb[, srid [, options]])}

  Constructs a \texttt{MultiPoint} value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.
MySQL-Specific Functions That Create Geometry Values

- **ST_MPolyFromWKB**(wkb[, srid [, options]]), **ST_MultiPolygonFromWKB**(wkb[, srid [, options]])

  Constructs a MultiPolygon value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

- **ST_PointFromWKB**(wkb[, srid [, options]])

  Constructs a Point value using its WKB representation and SRID.

  **ST_PointFromWKB()** handles its arguments as described in the introduction to this section.

- **ST_PolyFromWKB**(wkb[, srid [, options]]), **ST_PolygonFromWKB**(wkb[, srid [, options]])

  Constructs a Polygon value using its WKB representation and SRID.

  These functions handle their arguments as described in the introduction to this section.

### 12.16.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is **NULL**.

For example, you can insert the geometry return value from **Point()** directly into a **POINT** column:

```sql
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- **GeomCollection**(g [, g] ...)

  Constructs a GeomCollection value from the geometry arguments.

  **GeomCollection()** returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  **GeomCollection()** with no arguments is permitted as a way to create an empty geometry. Also, functions such as **ST_GeomFromText()** that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

  **GeomCollection()** and **GeometryCollection()** are synonymous, with **GeomCollection()** the preferred function.

- **GeometryCollection**(g [, g] ...)

  Constructs a GeomCollection value from the geometry arguments.

  **GeometryCollection()** returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  **GeometryCollection()** with no arguments is permitted as a way to create an empty geometry. Also, functions such as **ST_GeomFromText()** that accept WKT geometry collection arguments
understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- **LineString(pt [, pt] ...)**
  Constructs a LineString value from a number of Point or WKB Point arguments. If the number of arguments is less than two, the return value is NULL.

- **MultiLineString(ls [, ls] ...)**
  Constructs a MultiLineString value using LineString or WKB LineString arguments.

- **MultiPoint(pt [, pt2] ...)**
  Constructs a MultiPoint value using Point or WKB Point arguments.

- **MultiPolygon(poly [, poly] ...)**
  Constructs a MultiPolygon value from a set of Polygon or WKB Polygon arguments.

- **Point(x, y)**
  Constructs a Point using its coordinates.

- **Polygon(ls [, ls] ...)**
  Constructs a Polygon value from a number of LineString or WKB LineString arguments. If any argument does not represent a LinearRing (that is, not a closed and simple LineString), the return value is NULL.

### 12.16.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.16.3, “Functions That Create Geometry Values from WKT Values”, and Section 12.16.4, “Functions That Create Geometry Values from WKB Values”.

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce 'GEOMETRYCOLLECTION EMPTY' standard syntax:

```sql
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+--------------------------+--------------------------+
| ST_AsWKT(@s1)            | ST_AsWKT(@s2)            |
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+--------------------------+--------------------------+
mysql> SELECT ST_AsWKT(GeomCollection());
+---------------------------------+
| ST_AsWKT(GeomCollection())      |
+---------------------------------+
```
Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.

- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.

- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an **ER_WARN_SRS_NOT_FOUND_AXIS_ORDER** warning occurs.

- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is **NULL**, the return value is **NULL**. If the `options` argument is invalid, an error occurs to indicate why.

- Otherwise, the return value is non-**NULL**.

These functions are available for format conversions or coordinate swapping:

- **ST_AsBinary(g [, options]), ST_AsWKB(g [, options])**

  Converts a value in internal geometry format to its WKB representation and returns the binary result.

  The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

  **ST_AsBinary()** and **ST_AsWKB()** handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));     
+----------------------------------------------------------------+  
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)))                       |  
+----------------------------------------------------------------+  
| LINESTRING(5 0,10 5,15 10)                                    |  
+----------------------------------------------------------------+  
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
+----------------------------------------------------------------+  
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')))  |  
+----------------------------------------------------------------+  
| LINESTRING(0 5,10,10 15)                                      |  
+----------------------------------------------------------------+  
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
+----------------------------------------------------------------+  
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')))  |  
+----------------------------------------------------------------+  
| LINESTRING(5 0,10,15 10)                                      |  
+----------------------------------------------------------------+  

- **ST_AsText(g [, options]), ST_AsWKT(g [, options])**

  Converts a value in internal geometry format to its WKT representation and returns the string result.
The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional options argument may be given to override the default axis order.

**ST_AsText()** and **ST_AsWKT()** handle their arguments as described in the introduction to this section.

```sql
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+--------------------------+
| ST_AsText(ST_GeomFromText(@g)) |
+--------------------------+
| LINESTRING(1 1,2 2,3 3) |
+--------------------------+
```

Output for MultiPoint values includes parentheses around each point. For example:

```sql
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+---------------------------------+
| ST_AsText(ST_GeomFromText(@mp)) |
+---------------------------------+
| MULTIPOINT((1 1),(2 2),(3 3)) |
+---------------------------------+
```

- **ST_SwapXY(g)**

  Accepts an argument in internal geometry format, swaps the X and Y values of each coordinate pair within the geometry, and returns the result.

**ST_SwapXY()** handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)');
mysql> SELECT ST_AsText(@g);
+-----------------------------+
| ST_AsText(@g)              |
+-----------------------------+
| LINESTRING(0 5,5 10,10 15) |
+-----------------------------+
mysql> SELECT ST_AsText(ST_SwapXY(@g));
+-----------------------------+
| ST_AsText(ST_SwapXY(@g))   |
+-----------------------------+
| LINESTRING(5 0,10 5,15 10) |
+-----------------------------+
```

### 12.16.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return **NULL** if the argument is of an incorrect geometry type. For example, the **ST_Area()** polygon function returns **NULL** if the object type is neither **Polygon** nor **MultiPolygon**.

#### 12.16.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type. Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.
• If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

• If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

• If any SRID argument is not within the range of a 32-bit unsigned integer, an ER_DATA_OUT_OF_RANGE error occurs.

• If any SRID argument refers to an undefined SRS, an ER_SRS_NOT_FOUND error occurs.

• Otherwise, the return value is non-NUL.

These functions are available for obtaining geometry properties:

• **ST_Dimension(g)**

  Returns the inherent dimension of the geometry value g. The dimension can be −1, 0, 1, or 2. The meaning of these values is given in Section 11.5.2.2, “Geometry Class”.

  ST_Dimension() handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
+------------------------------------------------------+
| ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
+------------------------------------------------------+
| 1                                                   |
+------------------------------------------------------+
```

• **ST_Envelope(g)**

  Returns the minimum bounding rectangle (MBR) for the geometry value g. The result is returned as a Polygon value that is defined by the corner points of the bounding box:

  POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))

```sql
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
+----------------------------------------------------------------+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)'))) |
+----------------------------------------------------------------+
| POLYGON((1 1,2 1,2 2,1 2,1 1))                                |
+----------------------------------------------------------------+
```

If the argument is a point or a vertical or horizontal line segment, ST_Envelope() returns the point or the line segment as its MBR rather than returning an invalid polygon:

```sql
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
+----------------------------------------------------------------+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)'))) |
+----------------------------------------------------------------+
| LINESTRING(1 1,1 2)                                            |
+----------------------------------------------------------------+
```

ST_Envelope() handles its arguments as described in the introduction to this section, with this exception:

• If the geometry has an SRID value for a geographic spatial reference system (SRS), an ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.
Geometry Property Functions

- **ST_GeometryType**(g)
  Returns a binary string indicating the name of the geometry type of which the geometry instance g is a member. The name corresponds to one of the instantiable Geometry subclasses.
  
  ST_GeometryType() handles its arguments as described in the introduction to this section.

  ```
  mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
  +---------------------------------------------+
  | ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
  +---------------------------------------------+
  | POINT                                         |
  +---------------------------------------------+
  ```

- **ST_IsEmpty**(g)
  This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise.
  The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS EMPTY values such as POINT EMPTY.
  
  ST_IsEmpty() handles its arguments as described in the introduction to this section.

- **ST_IsSimple**(g)
  Returns 1 if the geometry value g is simple according to the ISO SQL/MM Part 3: Spatial standard.
  ST_IsSimple() returns 0 if the argument is not simple.
  
  The descriptions of the instantiable geometric classes given under Section 11.5.2, “The OpenGIS Geometry Model” include the specific conditions that cause class instances to be classified as not simple.
  
  ST_IsSimple() handles its arguments as described in the introduction to this section, with this exception:
  
  - If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
    - If any longitude argument is not in the range \((-180, 180]\), an ER_LONGITUDE_OUT_OF_RANGE error occurs.
    - If any latitude argument is not in the range \([-90, 90]\), an ER_LATITUDE_OUT_OF_RANGE error occurs.
  
  Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- **ST_SRID**(g[, srid])
  With a single argument representing a valid geometry object g, ST_SRID() returns an integer indicating the ID of the spatial reference system (SRS) associated with g.
  
  With the optional second argument representing a valid SRID value, ST_SRID() returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.
  
  ST_SRID() handles its arguments as described in the introduction to this section, with this exception:
  
  - For the single-argument syntax, ST_SRID() returns the geometry SRID even if it refers to an undefined SRS. An ER_SRS_NOT_FOUND error does not occur.
ST_SRID \( (g, \ target\_srid) \) and ST_Transform \( (g, \ target\_srid) \) differ as follows:

- **ST_SRID()** changes the geometry SRID value without transforming its coordinates.
- **ST_Transform()** transforms the geometry coordinates in addition to changing its SRID value.

```sql
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+-------------+
<table>
<thead>
<tr>
<th>ST_SRID(@g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+-------------+
<table>
<thead>
<tr>
<th>ST_SRID(@g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4326</td>
</tr>
</tbody>
</table>
```

It is possible to create a geometry in a particular SRID by passing to **ST_SRID()** the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

```sql
SET @g1 = ST_SRID(Point(1, 1), 4326);
```

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```sql
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of **ST_SRID()** is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.

### 12.16.7.2 Point Property Functions

A **Point** consists of X and Y coordinates, which may be obtained using the **ST_X()** and **ST_Y()** functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the **Point** object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For **Point** objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the **ST_Longitude()** and **ST_Latitude()** functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the **Point** object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is **NULL**, the return value is **NULL**.
- If any geometry argument is a valid geometry but not a **Point** object, an **ER_UNEXPECTED_GEOMETRY_TYPE** error occurs.
Geometry Property Functions

- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.

- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.

- If a longitude or latitude argument is out of range, an error occurs:
  - If any longitude argument is not in the range (-180, 180], an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If any latitude argument is not in the range [-90, 90], an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

  Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

  With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of `p` as a double-precision number.

  With the optional second argument representing a valid latitude value, `ST_Latitude()` returns a `Point` object like the first argument with its latitude equal to the second argument.

  `ST_Latitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+------------------+
| ST_Latitude(@pt) |
+------------------+
| 45               |
mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+---------------------------------+
| ST_AsText(ST_Latitude(@pt, 10)) |
| POINT(10 90)                  |
```

This function was added in MySQL 8.0.12.

- `ST_Longitude(p [, new_longitude_val])`

  With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Longitude()` returns the longitude value of `p` as a double-precision number.

  With the optional second argument representing a valid longitude value, `ST_Longitude()` returns a `Point` object like the first argument with its longitude equal to the second argument.
ST_Longitude() handles its arguments as described in the introduction to this section, with the addition that if the Point object is valid but does not have a geographic SRS, an ER_SRS_NOT_GEOGRAPHIC error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Longitude(@pt);
+-------------------+
| ST_Longitude(@pt) |
+-------------------+
|                90 |
+-------------------+
mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
+----------------------------------+
| ST_AsText(ST_Longitude(@pt, 10)) |
+----------------------------------+
| POINT(45 10)                   |
+----------------------------------+
```

This function was added in MySQL 8.0.12.

- **ST_X(p[, new_x_val])**

  With a single argument representing a valid Point object p, ST_X() returns the X-coordinate value of p as a double-precision number. As of MySQL 8.0.12, the X coordinate is considered to refer to the axis that appears first in the Point spatial reference system (SRS) definition.

  With the optional second argument, ST_X() returns a Point object like the first argument with its X coordinate equal to the second argument. As of MySQL 8.0.12, if the Point object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

  ST_X() handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_X(Point(56.7, 53.34));
+--------------------------+
| ST_X(Point(56.7, 53.34)) |
+--------------------------+
|                     56.7 |
+--------------------------+
mysql> SELECT ST_AsText(ST_X(Point(56.7, 53.34), 10.5));
+-------------------------------------------+
| ST_AsText(ST_X(Point(56.7, 53.34), 10.5)) |
+-------------------------------------------+
| POINT(10.5 53.34)                        |
+-------------------------------------------+
```

- **ST_Y(p[, new_y_val])**

  With a single argument representing a valid Point object p, ST_Y() returns the Y-coordinate value of p as a double-precision number. As of MySQL 8.0.12, the Y coordinate is considered to refer to the axis that appears second in the Point spatial reference system (SRS) definition.

  With the optional second argument, ST_Y() returns a Point object like the first argument with its Y coordinate equal to the second argument. As of MySQL 8.0.12, if the Point object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

  ST_Y() handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_Y(Point(56.7, 53.34));
```
12.16.7.3 LineString and MultiLineString Property Functions

A **LineString** consists of **Point** values. You can extract particular points of a **LineString**, count the number of points that it contains, or obtain its length.

Some functions in this section also work for **MultiLineString** values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is **NULL** or any geometry argument is an empty geometry, the return value is **NULL**.
- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- Otherwise, the return value is non-**NULL**.

These functions are available for obtaining linestring properties:

- **ST_EndPoint(ls)**

  Returns the **Point** that is the endpoint of the **LineString** value **ls**.

  **ST_EndPoint()** handles its arguments as described in the introduction to this section.

- **ST_IsClosed(ls)**

  For a **LineString** value **ls**, **ST_IsClosed()** returns 1 if **ls** is closed (that is, its **ST_StartPoint()** and **ST_EndPoint()** values are the same).

  For a **MultiLineString** value **ls**, **ST_IsClosed()** returns 1 if **ls** is closed (that is, the **ST_StartPoint()** and **ST_EndPoint()** values are the same for each **LineString** in **ls**).

  **ST_IsClosed()** returns 0 if **ls** is not closed, and **NULL** if **ls** is **NULL**.

  **ST_IsClosed()** handles its arguments as described in the introduction to this section, with this exception:
• If the geometry has an SRID value for a geographic spatial reference system (SRS), an 
  ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS error occurs.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
+------------------------------------+
| ST_IsClosed(ST_GeomFromText(@ls1)) |
+------------------------------------+
|                                  0 |
+------------------------------------+

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
+------------------------------------+
| ST_IsClosed(ST_GeomFromText(@ls2)) |
+------------------------------------+
|                                  1 |
+------------------------------------+

mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
+------------------------------------+
| ST_IsClosed(ST_GeomFromText(@ls3)) |
+------------------------------------+
|                                  0 |
+------------------------------------+
```

- **ST_Length(ls [, unit])**

  Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference system. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements.

  **ST_Length()** computes a result as follows:

  • If the geometry is a valid `LineString` in a Cartesian SRS, the return value is the Cartesian length of the geometry.

  • If the geometry is a valid `MultiLineString` in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.

  • If the geometry is a valid `LineString` in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.

  • If the geometry is a valid `MultiLineString` in a geographic SRS, the return value is the sum of the geodetic lengths of its elements in that SRS, in meters.

  **ST_Length()** handles its arguments as described in the introduction to this section, with these exceptions:

  • If the geometry is not a `LineString` or `MultiLineString`, the return value is `NULL`.

  • If the geometry is geometrically invalid, either the result is an undefined length (that is, it can be any number), or an error occurs.

  • If the length computation result is `+inf`, an ER_DATA_OUT_OF_RANGE error occurs.
• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  • If any longitude argument is not in the range \([-180, 180]\), an **ER_LONGITUDE_OUT_OF_RANGE** error occurs.
  • If any latitude argument is not in the range \([-90, 90]\), an **ER_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

As of MySQL 8.0.16, **ST_Length()** permits an optional *unit* argument that specifies the linear unit for the returned length value. These rules apply:

• If a unit is specified but not supported by MySQL, an **ER_UNIT_NOT_FOUND** error occurs.

• If a supported linear unit is specified and the SRID is 0, an **ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT** error occurs.

• If a supported linear unit is specified and the SRID is not 0, the result is in that unit.

• If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

A unit is supported if it is found in the **INFORMATION_SCHEMA ST_UNITS_OF_MEASURE** table. See Section 25.29, "The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table".

```sql
mysql> SET @ls = ST_GeomFromText('LineString(1 1,2 2,3 3)');
mysql> SELECT ST_Length(@ls);
+--------------------+
| ST_Length(@ls)     |
+--------------------+
| 2.8284271247461903 |
+--------------------+
mysql> SET @mls = ST_GeomFromText('MultiLineString((1 1,2 2,3 3),(4 4,5 5))');
mysql> SELECT ST_Length(@mls);
+-------------------+
| ST_Length(@mls)   |
+-------------------+
| 4.242640687119286 |
+-------------------+
mysql> SET @ls = ST_GeomFromText('LineString(1 1,2 2,3 3)', 4326);
mysql> SELECT ST_Length(@ls);
+-------------------+
| ST_Length(@ls)    |
+-------------------+
| 313701.962304328  |
+-------------------+
mysql> SELECT ST_Length(@ls, 'metre');
+-------------------------+
| ST_Length(@ls, 'metre') |
+-------------------------+
| 313701.962304328        |
+-------------------------+
mysql> SELECT ST_Length(@ls, 'foot');
+------------------------+
| ST_Length(@ls, 'foot') |
+------------------------+
| 1029205.9131247795     |
+------------------------+
```
Geometry Property Functions

• **ST_NumPoints(ls)**

Returns the number of Point objects in the LineString value `ls`.

`ST_NumPoints()` handles its arguments as described in the introduction to this section.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
           +------------------------------------+
+ ST_NumPoints(ST_GeomFromText(@ls)) | 3 |
+------------------------------------+
```

• **ST_PointN(ls, N)**

Returns the N-th Point in the Linestring value `ls`. Points are numbered beginning with 1.

`ST_PointN()` handles its arguments as described in the introduction to this section.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls), 2));
+-----------------------------------------------+
| ST_AsText(ST_PointN(ST_GeomFromText(@ls), 2)) |
| POINT(2 2)                                   |
+-----------------------------------------------+
```

• **ST_StartPoint(ls)**

Returns the Point that is the start point of the LineString value `ls`.

`ST_StartPoint()` handles its arguments as described in the introduction to this section.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
+-----------------------------------------------+
| ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
| POINT(1 1)                                   |
+-----------------------------------------------+
```

12.16.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of Polygon or MultiPolygon values.

Unless otherwise specified, functions in this section handle their arguments as follows:

• If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.

• If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

• If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

• For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an ER_GIS_DIFFERENT_SRIDS error occurs.

• Otherwise, the return value is non-NULL.
These functions are available for obtaining polygon properties:

- **ST_Area({poly|mpoly})**

  Returns a double-precision number indicating the area of the `Polygon` or `MultiPolygon` argument, as measured in its spatial reference system.

  As of MySQL 8.0.13, `ST_Area()` handles its arguments as described in the introduction to this section, with these exceptions:

  - If the geometry is geometrically invalid, either the result is an undefined area (that is, it can be any number), or an error occurs.
  
  - If the geometry is valid but is not a `Polygon` or `MultiPolygon` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
  
  - If the geometry is a valid `Polygon` in a Cartesian SRS, the result is the Cartesian area of the polygon.
  
  - If the geometry is a valid `MultiPolygon` in a Cartesian SRS, the result is the sum of the Cartesian area of the polygons.
  
  - If the geometry is a valid `Polygon` in a geographic SRS, the result is the geodetic area of the polygon in that SRS, in square meters.
  
  - If the geometry is a valid `MultiPolygon` in a geographic SRS, the result is the sum of geodetic area of the polygons in that SRS, in square meters.
  
  - If an area computation results in `+inf`, an `ER_DATA_OUT_OF_RANGE` error occurs.
  
  - If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
    
    - If any longitude argument is not in the range (-180, 180], an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
    
    - If any latitude argument is not in the range [-90, 90], an `ER_LATITUDE_OUT_OF_RANGE` error occurs.
  
  Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, `ST_Area()` handles its arguments as described in the introduction to this section, with these exceptions:

- For arguments of dimension 0 or 1, the result is 0.

- If a geometry is empty, the return value is 0 rather than `NULL`.

- For a geometry collection, the result is the sum of the area values of all components. If the geometry collection is empty, its area is returned as 0.

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
m昀sql> SELECT ST_Area(ST_GeomFromText(@poly));
+--------------------------+
<table>
<thead>
<tr>
<th>ST_Area(ST_GeomFromText(@poly))</th>
</tr>
</thead>
</table>
```
Geometry Property Functions

mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,1 1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
+----------------------------------+
|                                8 |

- **ST_Centroid({poly|mpoly})**

Returns the mathematical centroid for the Polygon or MultiPolygon argument as a Point. The result is not guaranteed to be on the MultiPolygon.

This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single MultiPolygon, MultiLineString, or MultiPoint for centroid computation.

**ST_Centroid()** handles its arguments as described in the introduction to this section, with these exceptions:

- The return value is **NULL** for the additional condition that the argument is an empty geometry collection.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs.

mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+------------------------+--------------------------------------------+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
+------------------------+--------------------------------------------+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |

- **ST_ExteriorRing(poly)**

Returns the exterior ring of the Polygon value poly as a LineString.

**ST_ExteriorRing()** handles its arguments as described in the introduction to this section.

mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,1 1 1))';
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
+----------------------------------------------------+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
+----------------------------------------------------+
| LINESTRING(0 0,0 3,3 3,3 0,0)                       |

- **ST_InteriorRingN(poly, N)**

Returns the N-th interior ring for the Polygon value poly as a LineString. Rings are numbered beginning with 1.
ST_InteriorRingN() handles its arguments as described in the introduction to this section.

mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
<table>
<thead>
<tr>
<th>ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINESTRING(1 1,1 2,2 2,2 1,1 1)</td>
</tr>
</tbody>
</table>

• ST_NumInteriorRing(poly), ST_NumInteriorRings(poly)

Returns the number of interior rings in the Polygon value poly.

ST_NumInteriorRing() and ST_NumInteriorRings() handle their arguments as described in the introduction to this section.

mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
<table>
<thead>
<tr>
<th>ST_NumInteriorRings(ST_GeomFromText(@poly))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

12.16.7.5 GeometryCollection Property Functions

These functions return properties of GeometryCollection values.

Unless otherwise specified, functions in this section handle their arguments as follows:

• If any argument is NULL or any geometry argument is an empty geometry, the return value is NULL.

• If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

• If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.

• Otherwise, the return value is non-NULL.

These functions are available for obtaining geometry collection properties:

• ST_GeometryN(gc, N)

Returns the N-th geometry in the GeometryCollection value gc. Geometries are numbered beginning with 1.

ST_GeometryN() handles its arguments as described in the introduction to this section.

mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
<table>
<thead>
<tr>
<th>ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(1 1)</td>
</tr>
</tbody>
</table>
• \texttt{ST\_NumGeometries(gc)}

Returns the number of geometries in the \texttt{GeometryCollection} value \( gc \).

\texttt{ST\_NumGeometries()} handles its arguments as described in the introduction to this section.

\begin{verbatim}
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST\_NumGeometries(ST\_GeomFromText(@gc));
+----------------------------------------+
<table>
<thead>
<tr>
<th>ST_NumGeometries(ST_GeomFromText(@gc))</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+----------------------------------------+
\end{verbatim}

12.16.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

Unless otherwise specified, functions in this section handle their arguments as follows:

• If any argument is \texttt{NULL}, the return value is \texttt{NULL}.

• If any geometry argument is not a syntactically well-formed geometry, an \texttt{ER\_GIS\_INVALID\_DATA} error occurs.

• If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an \texttt{ER\_SRS\_NOT\_FOUND} error occurs.

• For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an \texttt{ER\_GIS\_DIFFERENT\_SRIDS} error occurs.

• If any geometry argument has an SRID value for a geographic SRS, an \texttt{ER\_NOT\_IMPLEMENTED\_FOR\_GEOGRAPHIC\_SRS} error occurs.

• Otherwise, the return value is non-\texttt{NULL}.

These spatial operator functions are available:

• \texttt{ST\_Buffer(g, d[, strategy1[, strategy2[, strategy3]]])}

Returns a geometry that represents all points whose distance from the geometry value \( g \) is less than or equal to a distance of \( d \).

If the geometry argument is empty, \texttt{ST\_Buffer()} returns an empty geometry.

If the distance is 0, \texttt{ST\_Buffer()} returns the geometry argument unchanged:

\begin{verbatim}
mysql> SET @pt = ST\_GeomFromText('POINT(0 0)');
mysql> SELECT ST\_AsText(ST\_Buffer(@pt, 0));
+----------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_Buffer(@pt, 0))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(0 0)</td>
</tr>
</tbody>
</table>
+----------------------------------------+
\end{verbatim}
ST_Buffer() supports negative distances for Polygon and MultiPolygon values, and for geometry collections containing Polygon or MultiPolygon values. The result may be an empty geometry.

ST_Buffer() permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the ST_Buffer_Strategy() function, to be used for point, join, and end strategies:

- **Point strategies** apply to Point and MultiPoint geometries. If no point strategy is specified, the default is ST_Buffer_Strategy('point_circle', 32).

- **Join strategies** apply to LineString, MultiLineString, Polygon, and MultiPolygon geometries. If no join strategy is specified, the default is ST_Buffer_Strategy('join_round', 32).

- **End strategies** apply to LineString and MultiLineString geometries. If no end strategy is specified, the default is ST_Buffer_Strategy('end_round', 32).

Up to one strategy of each type may be specified, and they may be given in any order.

ST_Buffer() handles its arguments as described in the introduction to this section, with these exceptions:

- For a negative distance for Point, MultiPoint, LineString, and MultiLineString values, and for geometry collections not containing any Polygon or MultiPolygon values, an ER_WRONG_ARGUMENTS error occurs.

- If multiple strategies of a given type are specified, an ER_WRONG_ARGUMENTS error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
+--------------------------------------------+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
+--------------------------------------------+
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))       |
+--------------------------------------------+
```

```sql
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
+---------------------------------------------------------------+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))   |
| POLYGON((5 5,5 10,0 10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0 0,5 0,5 5))                                       |
+---------------------------------------------------------------+
```

**ST_Buffer_Strategy(strategy[, points_per_circle])**

This function returns a strategy byte string for use with ST_Buffer() to influence buffer computation. Information about strategies is available at Boost.org.

The first argument must be a string indicating a strategy option:

- For point strategies, permitted values are 'point_circle' and 'point_square'.
Spatial Operator Functions

- For join strategies, permitted values are 'join_round' and 'join_miter'.
- For end strategies, permitted values are 'end_round' and 'end_flat'.

If the first argument is 'point_circle', 'join_round', 'join_miter', or 'end_round', the points_per_circle argument must be given as a positive numeric value. The maximum points_per_circle value is the value of the max_points_in_geometry system variable.

For examples, see the description of ST_Buffer().

ST_Buffer_Strategy() handles its arguments as described in the introduction to this section, with these exceptions:

- If any argument is invalid, an ER_WRONG_ARGUMENTS error occurs.
- If the first argument is 'point_square' or 'end_flat', the points_per_circle argument must not be given or an ER_WRONG_ARGUMENTS error occurs.

ST_ConvexHull(g)

Returns a geometry that represents the convex hull of the geometry value g.

This function computes a geometry's convex hull by first checking whether its vertex points are collinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a MultiPoint value from them, and computing its convex hull.

ST_ConvexHull() handles its arguments as described in the introduction to this section, with this exception:

- The return value is NULL for the additional condition that the argument is an empty geometry collection.

```sql
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----------------------------------------------+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----------------------------------------------+
| POLYGON((5 0,25 0,15 25,5 0))                 |
+-----------------------------------------------+
```

ST_Difference(g1, g2)

Returns a geometry that represents the point set difference of the geometry values g1 and g2.

ST_Difference() handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+------------------------------------+
| ST_AsText(ST_Difference(@g1, @g2)) |
+------------------------------------+
| POINT(1 1)                         |
+------------------------------------+
```

ST_Intersection(g1, g2)

Returns a geometry that represents the point set intersection of the geometry values g1 and g2.

ST_Intersection() handles its arguments as described in the introduction to this section.
Spatial Operator Functions

Returns a geometry that represents the point set intersection of the geometry values \( g_1 \) and \( g_2 \).

**ST_Intersection()** handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
+--------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_Intersection(@g1, @g2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(2 2)</td>
</tr>
</tbody>
</table>
+--------------------------------------+
```

**ST_SymDifference\((g_1, \ g_2)\)**

Returns a geometry that represents the point set symmetric difference of the geometry values \( g_1 \) and \( g_2 \), which is defined as:

\[ g_1 \ symmetric \ difference \ g_2 := (g_1 \ union \ g_2) \ difference \ (g_1 \ intersection \ g_2) \]

Or, in function call notation:

\[
\text{ST_SymDifference}(g_1, g_2) = \text{ST_Difference}(\text{ST_Union}(g_1, g_2), \text{ST_Intersection}(g_1, g_2))
\]

**ST_SymDifference()** handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
+---------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_SymDifference(@g1, @g2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTIPOINT((1 1),(2 2))</td>
</tr>
</tbody>
</table>
+---------------------------------------+
```

**ST_Transform\((g, \ target\_srid)\)**

Transforms a geometry from one spatial reference system (SRS) to another. The return value is a geometry of the same type as the input geometry with all coordinates transformed to the target SRID, `target_srid`. Transformation support is limited to geographic SRSs, unless the SRID of the geometry argument is the same as the target SRID value, in which case the return value is the input geometry for any valid SRS.

**ST_Transform()** handles its arguments as described in the introduction to this section, with these exceptions:

- Geometry arguments that have an SRID value for a geographic SRS do not produce an error.
- If the geometry or target SRID argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If the geometry is in an SRS that `ST_Transform()` cannot transform from, an `ER_TRANSFORM_SOURCE_SRS_NOT_SUPPORTED` error occurs.
- If the target SRID is in an SRS that `ST_Transform()` cannot transform to, an `ER_TRANSFORM_TARGET_SRS_NOT_SUPPORTED` error occurs.
Spatial Operator Functions

- If the geometry is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_SOURCE_SRS_MISSING_TOWGS84` error occurs.

- If the target SRID is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_TARGET_SRS_MISSING_TOWGS84` error occurs.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```sql
mysql> SET @p = ST_GeomFromText('POINT(52.381389 13.064444)', 4326);
mysql> SELECT ST_AsText(@p);
+----------------------------+
| ST_AsText(@p)              |
+----------------------------+
| POINT(52.381389 13.064444) |
+----------------------------+

mysql> SET @p = ST_Transform(@p, 4230);
mysql> SELECT ST_AsText(@p);
+---------------------------------------------+
| ST_AsText(@p)                               |
+---------------------------------------------+
| POINT(52.38208611407426 13.065520672345304) |
+---------------------------------------------+
```

- `ST_Union(g1, g2)`

Returns a geometry that represents the point set union of the geometry values `g1` and `g2`.

`ST_Union()` handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
+--------------------------------------+
| ST_AsText(ST_Union(@g1, @g2))        |
+--------------------------------------+
| MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
+--------------------------------------+
```

In addition, Section 12.16.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `ST_Envelope(g)`
- `ST_StartPoint(ls)`
- `ST_EndPoint(ls)`
- `ST_PointN(ls, N)`
- `ST_ExteriorRing(poly)`
- `ST_InteriorRingN(poly, N)`
- `ST_GeometryN(gc, N)`
12.16.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

12.16.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values \( g_1 \) and \( g_2 \), using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except for \( \text{ST_Distance()} \), which returns distance values.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is \texttt{NULL} or any geometry argument is an empty geometry, the return value is \texttt{NULL}.
- If any geometry argument is not a syntactically well-formed geometry, an \texttt{ER_GIS_INVALID_DATA} error occurs.
- If any geometry argument refers to an undefined spatial reference system (SRS), an \texttt{ER_SRS_NOT_FOUND} error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an \texttt{ER_GIS_DIFFERENT_SRIDS} error occurs.
- If any geometry argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range \((-180, 180]\), an \texttt{ER_LONGITUDE_OUT_OF_RANGE} error occurs.
  - If a latitude value is not in the range \([-90, 90]\), an \texttt{ER_LATITUDE_OUT_OF_RANGE} error occurs.

These object-shape functions are available for testing geometry relationships:

- \( \text{ST_Contains}(g_1, g_2) \)
  Returns 1 or 0 to indicate whether \( g_1 \) completely contains \( g_2 \). This tests the opposite relationship as \( \text{ST_Within()} \).
  \( \text{ST_Contains()} \) handles its arguments as described in the introduction to this section.

- \( \text{ST_Crosses}(g_1, g_2) \)
  Two geometries \textit{spatially cross} if their spatial relation has the following properties:
Functions That Test Spatial Relations Between Geometry Objects

- Unless $g_1$ and $g_2$ are both of dimension 1: $g_1$ crosses $g_2$ if the interior of $g_2$ has points in common with the interior of $g_1$, but $g_2$ does not cover the entire interior of $g_1$.

- If both $g_1$ and $g_2$ are of dimension 1: If the lines cross each other in a finite number of points (that is, no common line segments, only single points in common).

This function returns 1 or 0 to indicate whether $g_1$ spatially crosses $g_2$.

$ST_Crosses()$ handles its arguments as described in the introduction to this section except that the return value is $NULL$ for these additional conditions:

- $g_1$ is of dimension 2 ($Polygon$ or $MultiPolygon$).
- $g_2$ is of dimension 1 ($Point$ or $MultiPoint$).

$ST_Disjoint(g_1, g_2)$

Returns 1 or 0 to indicate whether $g_1$ is spatially disjoint from (does not intersect) $g_2$.

$ST_Disjoint()$ handles its arguments as described in the introduction to this section.

$ST_Distance(g_1, g_2 [, \text{unit}])$

Returns the distance between $g_1$ and $g_2$, measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the unit of the optional $\text{unit}$ argument if that is specified.

This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

$ST_Distance()$ handles its geometry arguments as described in the introduction to this section, with these exceptions:

- $ST_Distance()$ detects arguments in a geographic (ellipsoidal) spatial reference system and returns the geodetic distance on the ellipsoid. The only permitted geographic argument types are $Point$ and $Point$, or $Point$ and $MultiPoint$ (in any argument order). If called with other geometry type argument combinations in a geographic SRS, an $ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS$ error occurs.

- If any argument is geometrically invalid, either the result is an undefined distance (that is, it can be any number), or an error occurs.

- If an intermediate or final result produces $NaN$ or a negative number, an $ER_GIS_INVALID_DATA$ error occurs.

As of MySQL 8.0.14, $ST_Distance()$ permits an optional $\text{unit}$ argument that specifies the linear unit for the returned distance value. These rules apply:

- If a unit is specified but not supported by MySQL, an $ER_UNIT_NOT_FOUND$ error occurs.

- If a supported linear unit is specified and the SRID is 0, an $ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT$ error occurs.

- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.

- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.
Functions That Test Spatial Relations Between Geometry Objects

A unit is supported if it is found in the INFORMATION_SCHEMA ST_UNITS_OF_MEASURE table. See Section 25.29, “The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table”.

```
mysql> SET @g1 = Point(1,1);
mysql> SET @g2 = Point(2,2);
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
+-----------------------+
| 1.4142135623730951    |
+-----------------------+
mysql> SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)', 4326);
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
+-----------------------+
| 156874.3859490455     |
+-----------------------+
```

For the special case of distance calculations on a sphere, see the ST_Distance_Sphere() function.

- **ST_Equals(g1, g2)**

  Returns 1 or 0 to indicate whether g1 is spatially equal to g2.

  ST_Equals() handles its arguments as described in the introduction to this section, except that it does not return NULL for empty geometry arguments.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+---------------------+---------------------+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+---------------------+---------------------+
|                   1 |                   0 |
+---------------------+---------------------+
```

- **ST_Intersects(g1, g2)**

  Returns 1 or 0 to indicate whether g1 spatially intersects g2.

  ST_Intersects() handles its arguments as described in the introduction to this section.

- **ST_Overlaps(g1, g2)**

  Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
Functions That Test Spatial Relations Between Geometry Objects

This function returns 1 or 0 to indicate whether \( g_1 \) spatially overlaps \( g_2 \).

\texttt{ST	extunderscore Overlaps()} handles its arguments as described in the introduction to this section except that the return value is \texttt{NULL} for the additional condition that the dimensions of the two geometries are not equal.

- \texttt{ST	extunderscore Touches(g1, g2)}

Two geometries \textit{spatially touch} if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether \( g_1 \) spatially touches \( g_2 \).

\texttt{ST	extunderscore Touches()} handles its arguments as described in the introduction to this section except that the return value is \texttt{NULL} for the additional condition that both geometries are of dimension 0 (\texttt{Point} or \texttt{MultiPoint}).

- \texttt{ST	extunderscore Within(g1, g2)}

Returns 1 or 0 to indicate whether \( g_1 \) is spatially within \( g_2 \). This tests the opposite relationship as \texttt{ST	extunderscore Contains()}. 

\texttt{ST	extunderscore Within()} handles its arguments as described in the introduction to this section.

12.16.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries \( g_1 \) and \( g_2 \). The return values 1 and 0 indicate true and false, respectively.

The bounding box of a point is interpreted as a point that is both boundary and interior.

The bounding box of a straight horizontal or vertical line is interpreted as a line where the interior of the line is also boundary. The endpoints are boundary points.

If any of the parameters are geometry collections, the interior, boundary, and exterior of those parameters are those of the union of all elements in the collection.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is \texttt{NULL} or an empty geometry, the return value is \texttt{NULL}.

- If any geometry argument is not a syntactically well-formed geometry, an \texttt{ER	extunderscore GIS	extunderscore INVALID	extunderscore DATA} error occurs.

- If any geometry argument refers to an undefined spatial reference system (SRS), an \texttt{ER	extunderscore SRS	extunderscore NOT	extunderscore FOUND} error occurs.

- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an \texttt{ER	extunderscore GIS	extunderscore DIFFERENT	extunderscore SRIDS} error occurs.

- If any argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.

- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs.
 Functions That Test Spatial Relations Between Geometry Objects

- If a longitude value is not in the range \((-180, 180]\), an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range \([-90, 90]\), an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These MBR functions are available for testing geometry relationships:

- \( \text{MBRContains}(g1, g2) \)

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g1\) contains the minimum bounding rectangle of \(g2\). This tests the opposite relationship as \(\text{MBRWithin}()\).

  \(\text{MBRContains}()\) handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
  mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
  mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
  +----------------------+--------------------+
  | MBRContains(@g1,@g2) | MBRWithin(@g2,@g1) |
  +----------------------+--------------------+
  |                    1 |                  1 |
  +----------------------+--------------------+
  ```

- \( \text{MBRCoveredBy}(g1, g2) \)

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g1\) is covered by the minimum bounding rectangle of \(g2\). This tests the opposite relationship as \(\text{MBRCovers}()\).

  \(\text{MBRCoveredBy}()\) handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
  mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
  mysql> SELECT MBRCovers(@g1,@g2), MBRCoveredby(@g1,@g2);
  +--------------------+-----------------------+
  | MBRCovers(@g1,@g2) | MBRCoveredby(@g1,@g2) |
  +--------------------+-----------------------+
  |                  1 |                     0 |
  +--------------------+-----------------------+
  mysql> SELECT MBRCovers(@g2,@g1), MBRCoveredby(@g2,@g1);
  +--------------------+-----------------------+
  | MBRCovers(@g2,@g1) | MBRCoveredby(@g2,@g1) |
  +--------------------+-----------------------+
  |                  0 |                     1 |
  +--------------------+-----------------------+
  ```

- \( \text{MBRCovers}(g1, g2) \)

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g1\) covers the minimum bounding rectangle of \(g2\). This tests the opposite relationship as \(\text{MBRCoveredBy}()\). See the description of \(\text{MBRCoveredBy}()\) for examples.

  \(\text{MBRCovers}()\) handles its arguments as described in the introduction to this section.

- \( \text{MBRDisjoint}(g1, g2) \)
Functions That Test Spatial Relations Between Geometry Objects

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g_1 \) and \( g_2 \) are disjoint (do not intersect).

\textbf{MBRDisjoint()} handles its arguments as described in the introduction to this section.

- \textbf{MBREquals}(\( g_1, g_2 \))

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g_1 \) and \( g_2 \) are the same.

\textbf{MBREquals()} handles its arguments as described in the introduction to this section, except that it does not return \texttt{NULL} for empty geometry arguments.

- \textbf{MBRIntersects}(\( g_1, g_2 \))

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g_1 \) and \( g_2 \) intersect.

\textbf{MBRIntersects()} handles its arguments as described in the introduction to this section.

- \textbf{MBROverlaps}(\( g_1, g_2 \))

Two geometries \textit{spatially overlap} if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g_1 \) and \( g_2 \) overlap.

\textbf{MBROverlaps()} handles its arguments as described in the introduction to this section.

- \textbf{MBRTouches}(\( g_1, g_2 \))

Two geometries \textit{spatially touch} if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g_1 \) and \( g_2 \) touch.

\textbf{MBRTouches()} handles its arguments as described in the introduction to this section.

- \textbf{MBRWithin}(\( g_1, g_2 \))

Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g_1 \) is within the minimum bounding rectangle of \( g_2 \). This tests the opposite relationship as \textbf{MBRContains()}.

\textbf{MBRWithin()} handles its arguments as described in the introduction to this section.

```sql
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
m有限> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
m有限> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+--------------------+--------------------+
|                  1 |                  0 |
```
Spatial Geohash Functions

12.16.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvwxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

Unless otherwise specified, functions in this section handle their arguments as follows:

• If any argument is NULL, the return value is NULL.
• If any argument is invalid, an error occurs.
• If any argument has a longitude or latitude that is out of range, an error occurs:
  • If any longitude argument is not in the range \((-180, 180]\), an ER_LONGITUDE_OUT_OF_RANGE error occurs.
  • If any latitude argument is not in the range \([-90, 90]\), an ER_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

• If any point argument does not have SRID 0 or 4326, an ER_SRS_NOT_FOUND error occurs. point argument SRID validity is not checked.
• If any SRID argument refers to an undefined spatial reference system (SRS), an ER_SRS_NOT_FOUND error occurs.
• If any SRID argument is not within the range of a 32-bit unsigned integer, an ER_DATA_OUT_OF_RANGE error occurs.
• Otherwise, the return value is non-NULL.

These geohash functions are available:

• `ST_GeoHash(longitude, latitude, max_length)`, `ST_GeoHash(point, max_length)`

Returns a geohash string in the connection character set and collation.

For the first syntax, the `longitude` must be a number in the range \([-180, 180]\), and the `latitude` must be a number in the range \([-90, 90]\). For the second syntax, a POINT value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

The resulting string is no longer than `max_length` characters, which has an upper limit of 100. The string might be shorter than `max_length` characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or `max_length` characters, whichever comes first.

`ST_GeoHash()` handles its arguments as described in the introduction to this section.

```sql
mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
+----------------------+-------------------------+
| ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
| xbpbpbpbpb          | 000000000000000         |
+----------------------+-------------------------+
```
Spatial Geohash Functions

- **ST_LatFromGeoHash** (*geohash_str*)

  Returns the latitude from a geohash string value, as a double-precision number in the range \([-90, 90]\).

  The **ST_LatFromGeoHash**() decoding function reads no more than 433 characters from the *geohash_str* argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

  **ST_LatFromGeoHash**() handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45,-20,10));
  +------------------------------------------+
  | ST_LatFromGeoHash(ST_GeoHash(45,-20,10)) |
  +------------------------------------------+
  |                                      -20 |
  +------------------------------------------+
  
  mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
  +-------------------------------------------+
  | ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
  +-------------------------------------------+
  |                                        45 |
  +-------------------------------------------+
  
  mysql> SET @gh = ST_GeoHash(45,-20,10);
  mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
  +---------------------------------------+
  | ST_AsText(ST_PointFromGeoHash(@gh,0)) |
  +---------------------------------------+
  | POINT(45 -20)                         |
  +---------------------------------------+
  ```

- **ST_LongFromGeoHash** (*geohash_str*)

  Returns the longitude from a geohash string value, as a double-precision number in the range \([-180, 180]\).

  The remarks in the description of **ST_LatFromGeoHash**() regarding the maximum number of characters processed from the *geohash_str* argument also apply to **ST_LongFromGeoHash**().

  **ST_LongFromGeoHash**() handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
  +-------------------------------------------+
  | ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
  +-------------------------------------------+
  |                                        45 |
  +-------------------------------------------+
  ```

- **ST_PointFromGeoHash** (*geohash_str*, *srid*)

  Returns a **POINT** value containing the decoded geohash value, given a geohash string value.

  The X and Y coordinates of the point are the longitude in the range \([-180, 180]\) and the latitude in the range \([-90, 90]\), respectively.

  The *srid* argument is an 32-bit unsigned integer.

  The remarks in the description of **ST_LatFromGeoHash**() regarding the maximum number of characters processed from the *geohash_str* argument also apply to **ST_PointFromGeoHash**().

  **ST_PointFromGeoHash**() handles its arguments as described in the introduction to this section.

  ```sql
  mysql> SET @gh = ST_GeoHash(45,-20,10);
  mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
  +---------------------------------------+
  | ST_AsText(ST_PointFromGeoHash(@gh,0)) |
  +---------------------------------------+
  | POINT(45 -20)                         |
  +---------------------------------------+
  ```
Spatial GeoJSON Functions

12.16.11 Spatial GeoJSON Functions
This section describes functions for converting between GeoJSON documents and spatial values.
GeoJSON is an open standard for encoding geometric/geographical features. For more information, see
http://geojson.org. The functions discussed here follow GeoJSON specification revision 1.0.
GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and
FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS
support is limited to values that identify an SRID.
MySQL also supports a native JSON data type and a set of SQL functions to enable operations on JSON
values. For more information, see Section 11.6, “The JSON Data Type”, and Section 12.17, “JSON
Functions”.
• ST_AsGeoJSON(g [, max_dec_digits [, options]])
Generates a GeoJSON object from the geometry g. The object string has the connection character set
and collation.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.
max_dec_digits, if specified, limits the number of decimal digits for coordinates and causes rounding
32
of output. If not specified, this argument defaults to its maximum value of 2 − 1. The minimum is 0.
options, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry
argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

Flag
Value

Meaning

0

No options. This is the default if options is not specified.

1

Add a bounding box to the output.

2

Add a short-format CRS URN to the output. The default format is a short format
(EPSG:srid).

4

Add a long-format CRS URN (urn:ogc:def:crs:EPSG::srid). This flag overrides flag
2. For example, option values of 5 and 7 mean the same (add a bounding box and a longformat CRS URN).

mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2);
+-------------------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2) |
+-------------------------------------------------------------+
| {"type": "Point", "coordinates": [11.11, 12.22]}
|
+-------------------------------------------------------------+

• ST_GeomFromGeoJSON(str [, options [, srid]])
Parses a string str representing a GeoJSON object and returns a geometry.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.
options, if given, describes how to handle GeoJSON documents that contain geometries with
coordinate dimensions higher than 2. The following table shows the permitted options values.
2012


### Spatial Convenience Functions

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Reject the document and produce an error. This is the default if <code>options</code> is not specified.</td>
</tr>
<tr>
<td>2, 3, 4</td>
<td>Accept the document and strip off the coordinates for higher coordinate dimensions.</td>
</tr>
</tbody>
</table>

`options` values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, these values will produce different effects.

The `srid` argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

If `srid` refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range \((-180, 180]\), an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range \([-90, 90]\), an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

GeoJSON geometry, feature, and feature collection objects may have a `crs` property. The parsing function parses named CRS URNs in the `urn:ogc:def:crs:EPSG::srid` and `EPSG:srid` namespaces, but not CRSs given as link objects. Also, `urn:ogc:def:crs:OGC:1.3:CRS84` is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional `srid` argument is given, any CRS is ignored even if it is invalid.

If a `crs` member that specifies an SRID different from the top-level object SRID is found at a lower level of the GeoJSON document, an `ER_INVALID_GEOJSON_CRS_NOT_TOP_LEVEL` error occurs.

As specified in the GeoJSON specification, parsing is case sensitive for the `type` member of the GeoJSON input (Point, LineString, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case-sensitive.

This example shows the parsing result for a simple GeoJSON object:

```sql
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0]}';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+--------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_GeomFromGeoJSON(@json))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(102 0)</td>
</tr>
</tbody>
</table>
+--------------------------------------+
```

### 12.16.12 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`. 
Spatial Convenience Functions

- If any geometry argument is not a syntactically well-formed geometry, an **ER_GIS_INVALID_DATA** error occurs.
- If any geometry argument has an SRID value that refers to an undefined spatial reference system (SRS), an **ER_SRS_NOT_FOUND** error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an **ER_GIS_DIFFERENT_SRIDS** error occurs.
- Otherwise, the return value is non-**NULL**.

These convenience functions are available:

- **ST_Distance_Sphere(g1, g2 [, radius])**
  
  Returns the minimum spherical distance between Point or MultiPoint arguments on a sphere, in meters. (For general-purpose distance calculations, see the **ST_Distance()** function.) The optional **radius** argument should be given in meters.

  If both geometry parameters are valid Cartesian Point or MultiPoint values in SRID 0, the return value is shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is 6,370,986 meters, Point X and Y coordinates are interpreted as longitude and latitude, respectively, in degrees.

  If both geometry parameters are valid Point or MultiPoint values in a geographic spatial reference system (SRS), the return value is the shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is equal to the mean radius, defined as (2a+b)/3, where a is the semi-major axis and b is the semi-minor axis of the SRS.

  **ST_Distance_Sphere()** handles its arguments as described in the introduction to this section, with these exceptions:

  - Supported geometry argument combinations are Point and Point, or Point and MultiPoint (in any argument order). If at least one of the geometries is neither Point nor MultiPoint, and its SRID is 0, an **ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS** error occurs. If at least one of the geometries is neither Point nor MultiPoint, and its SRID refers to a geographic SRS, an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs. If any geometry refers to a projected SRS, an **ER_NOT_IMPLEMENTED_FOR_PROJECTED_SRS** error occurs.

  - If any argument has a longitude or latitude that is out of range, an error occurs:
    - If any longitude argument is not in the range \((-180, 180]\), an **ER_LONGITUDE_OUT_OF_RANGE** error occurs.
    - If any latitude argument is not in the range \([-90, 90]\), an **ER_LATITUDE_OUT_OF_RANGE** error occurs.

      Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

  - If the **radius** argument is present but not positive, an **ER_NONPOSITIVE_RADIUS** error occurs.

  - If the distance exceeds the range of a double-precision number, an **ER_STD_OVERFLOW_ERROR** error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
m.mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
```
Spatial Convenience Functions

mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+--------------------------------+
| ST_Distance_Sphere(@pt1, @pt2) |
| 20015042.813723423              |
+--------------------------------+

• **ST_IsValid(g)**

Returns 1 if the argument is geometrically valid, 0 if the argument is not geometrically valid. Geometry validity is defined by the OGC specification.

The only valid empty geometry is represented in the form of an empty geometry collection value. **ST_IsValid()** returns 1 in this case. MySQL does not support GIS EMPTY values such as POINT EMPTY.

**ST_IsValid()** handles its arguments as described in the introduction to this section, with this exception:

• If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  • If any longitude argument is not in the range (-180, 180], an ER_LONGITUDE_OUT_OF_RANGE error occurs.
  • If any latitude argument is not in the range [-90, 90], an ER_LATITUDE_OUT_OF_RANGE error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,-0.00 0,0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+------------------+
| ST_IsValid(@ls1) |
| 0                |
+------------------+
mysql> SELECT ST_IsValid(@ls2);
+------------------+
| ST_IsValid(@ls2) |
| 1                |
+------------------+

• **ST_MakeEnvelope(pt1, pt2)**

Returns the rectangle that forms the envelope around two points, as a Point, LineString, or Polygon.

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points pt1 and pt2, **ST_MakeEnvelope()** creates the result geometry on an abstract plane like this:

• If pt1 and pt2 are equal, the result is the point pt1.
• Otherwise, if \((pt1, pt2)\) is a vertical or horizontal line segment, the result is the line segment \((pt1, pt2)\).

• Otherwise, the result is a polygon using \(pt1\) and \(pt2\) as diagonal points.

The result geometry has an SRID of 0.

\textit{ST_MakeEnvelope()} handles its arguments as described in the introduction to this section, with these exceptions:

• If the arguments are not \textbf{Point} values, an \textbf{ER_WRONG_ARGUMENTS} error occurs.

• An \textbf{ER_GIS_INVALID_DATA} error occurs for the additional condition that any coordinate value of the two points is infinite or \textbf{NaN}.

• If any geometry has an SRID value for a geographic spatial reference system (SRS), an \textbf{ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS} error occurs.

\begin{verbatim}
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+----------------------------------------+
| ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
+----------------------------------------+
| POLYGON((0 0,1 0,1 1,0 1,0 0))         |
+----------------------------------------+
\end{verbatim}

• \textit{ST_Simplify}(g, \textit{max_distance})

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type.

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The \textit{max_distance} argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to \textit{ST_IsValid()}.

\textit{ST_Simplify()} handles its arguments as described in the introduction to this section, with this exception:

• If the \textit{max_distance} argument is not positive, or is \textbf{NaN}, an \textbf{ER_WRONG_ARGUMENTS} error occurs.

\begin{verbatim}
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
+---------------------------------+
| ST_AsText(ST_Simplify(@g, 0.5)) |
+---------------------------------+
| LINESTRING(0 0,0 1,1 1,2 3,3 3) |
+---------------------------------+
mysql> SELECT ST_AsText(ST_Simplify(@g, 1.0));
+---------------------------------+
\end{verbatim}
### ST_Validate(g)

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid:

```
POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))
```

ST_Validate() returns the geometry if it is syntactically well-formed and is geometrically valid, **NULL** if the argument is not syntactically well-formed or is not geometrically valid or is **NULL**.

ST_Validate() can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input Polygon or MultiPolygon has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. ST_Validate() returns it directly without further checks in this case.

As of MySQL 8.0.13, ST_Validate() handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If any longitude argument is not in the range (−180, 180], an **ER_LONGITUDE_OUT_OF_RANGE** error occurs.
  - If any latitude argument is not in the range [−90, 90], an **ER_LATITUDE_OUT_OF_RANGE** error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, ST_Validate() handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not syntactically well-formed, the return value is **NULL**. An **ER_GIS_INVALID_DATA** error does not occur.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an **ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS** error occurs.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_AsText(ST_Validate(@ls1));
+-------------------+
| ST_AsText(ST_Validate(@ls1)) |
+-------------------+
| NULL              |
+-------------------+
mysql> SELECT ST_AsText(ST_Validate(@ls2));
+-------------------+
| ST_AsText(ST_Validate(@ls2)) |
+-------------------+
| LINESTRING(0 0, 1 1) |
+-------------------+
```
12.17 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the JSON data type and additional examples showing how to use these functions, see Section 11.6, “The JSON Data Type”.

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by `json_doc`; arguments indicated by `val` are not parsed.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.16.11, “Spatial GeoJSON Functions”.

12.17.1 JSON Function Reference

Table 12.21 JSON Functions

<table>
<thead>

</tbody>
</table>

MySQL supports two aggregate JSON functions JSON_ARRAYAGG() and JSON_OBJECTAGG(). See Section 12.20, “Aggregate (GROUP BY) Functions”, for descriptions of these.

MySQL also supports “pretty-printing” of JSON values in an easy-to-read format, using the JSON_PRETTY() function. You can see how much storage space a given JSON value takes up, and how much space remains for additional storage, using JSON_STORAGE_SIZE() and JSON_STORAGE_FREE(), respectively. For complete descriptions of these functions, see Section 12.17.7, “JSON Utility Functions”.

12.17.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.

• JSON_ARRAY([val[, val] ...])

Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

```
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+---------------------------------------------+
| JSON_ARRAY(1, "abc", NULL, TRUE, "11:30:24.000000") |
+---------------------------------------------+
```

• JSON_OBJECT([key, val[, key, val] ...])

Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An error occurs if any key name is NULL or the number of arguments is odd.

```
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
+-----------------------------------------+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----------------------------------------+
```

• JSON_QUOTE(string)

Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a utf8mb4 string. Returns NULL if the argument is NULL.

This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

Certain special characters are escaped with backslashes per the escape sequences shown in Table 12.22, “JSON_UNQUOTE() Special Character Escape Sequences”.

2019
You can also obtain JSON values by casting values of other types to the JSON type using `CAST(value AS JSON)`; see Converting between JSON and non-JSON values, for more information.

Two aggregate functions generating JSON values are available. `JSON_ARRAYAGG()` returns a result set as a single JSON array, and `JSON_OBJECTAGG()` returns a result set as a single JSON object. For more information, see Section 12.20, “Aggregate (GROUP BY) Functions”.

### 12.17.3 Functions That Search JSON Values

The functions in this section perform search operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them.

- **`JSON_CONTAINS(target, candidate[, path])`**

  Indicates by returning 1 or 0 whether a given candidate JSON document is contained within a target JSON document, or—if a path argument was supplied—whether the candidate is found at a specific path within the target. Returns `NULL` if any argument is `NULL`, or if the path argument does not identify a section of the target document. An error occurs if `target` or `candidate` is not a valid JSON document, or if the path argument is not a valid path expression or contains a `*` or `**` wildcard.

  To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

  The following rules define containment:

  - A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.

  - A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.

  - A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.

  - A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

  Otherwise, the candidate value is not contained in the target document.
Functions That Search JSON Values

| JSON_CONTAINS(@j, @j2, '$.a') | 1 |
|-------------------------------+---|

mysql> SELECT JSON_CONTAINS(@j, @j2, '$.b');

| JSON_CONTAINS(@j, @j2, '$.b') | 0 |
|-------------------------------+---|

mysql> SET @j2 = '{"d": 4}';

mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');

| JSON_CONTAINS(@j, @j2, '$.a') | 0 |
|-------------------------------+---|

mysql> SELECT JSON_CONTAINS(@j, @j2, '$.c');

| JSON_CONTAINS(@j, @j2, '$.c') | 1 |
|-------------------------------+---|

• JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document, any path argument is not a valid path expression, or one_or_all is not 'one' or 'all'.

To check for a specific value at a path, use JSON_CONTAINS() instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the one_or_all argument:

• 'one': 1 if at least one path exists within the document, 0 otherwise.
• 'all': 1 if all paths exist within the document, 0 otherwise.

mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';

mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e');

| JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e') | 1 |
|---------------------------------------------+---|

mysql> SELECT JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e');

| JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e') | 0 |
|---------------------------------------------+---|

mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d');

| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') | 1 |
|----------------------------------------+---|

mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d');

| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') | 0 |

2021
Functions That Search JSON Values

- **JSON_EXTRACT(json_doc, path[, path] ...)**

Returns data from a JSON document, selected from the parts of the document matched by the `path` arguments. Returns `NULL` if any argument is `NULL` or no paths locate a value in the document. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression.

The return value consists of all values matched by the `path` arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

```sql
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]');
+--------------------------------------------+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]') |
+--------------------------------------------+
| 20                                         |
+--------------------------------------------+

mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]');
+----------------------------------------------------+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]') |
+----------------------------------------------------+
| [20, 10]                                           |
+----------------------------------------------------+

mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]');
+-----------------------------------------------+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]') |
+-----------------------------------------------+
| [30, 40]                                      |
+-----------------------------------------------+
```

MySQL supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a JSON column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- **column->path**

The `->` operator serves as an alias for the `JSON_EXTRACT()` function when used with two arguments, a column identifier on the left and a JSON path on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column identifiers wherever they occur in SQL statements.

The two `SELECT` statements shown here produce the same output:

```sql
mysql> SELECT c, JSON_EXTRACT(c, "$.id"), g
    > FROM jemp
    > WHERE JSON_EXTRACT(c, "$.id") > 1
    > ORDER BY JSON_EXTRACT(c, "$.name");
+-------------------------------+-----------+------+
<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
</tr>
</tbody>
</table>
+-------------------------------+-----------+------+
3 rows in set (0.00 sec)

mysql> SELECT c, c->"$.id", g
    > FROM jemp
    > WHERE c->"$.id" > 1
```
Functions That Search JSON Values

> ORDER BY c->"$.name";

<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

This functionality is not limited to `SELECT`, as shown here:

```sql
mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT c, c->"$.id", g, n
   > FROM jemp
   > WHERE JSON_EXTRACT(c, "$$.id") > 1
   > ORDER BY c->"$.name";

<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
<td>NULL</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
<td>NULL</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n
   > FROM jemp
   > WHERE JSON_EXTRACT(c, "$$.id") > 1
   > ORDER BY c->"$.name";

<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
<td>NULL</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
<td>NULL</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

(See Indexing a Generated Column to Provide a JSON Column Index, for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10
   > VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,22,44,66]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]" FROM tj10;
```

2023
Functions That Search JSON Values

```
| 44 |
| [22, 44, 66] |
```

2 rows in set (0.00 sec)

mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
```
+---------+------+
| a       | b    |
+---------+------+
| [3, 10, 5, 17, 44] | 33   |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+---------+------+
```

2 rows in set (0.00 sec)

Nested arrays are supported. An expression using -> evaluates as NULL if no matching key is found in the target JSON document, as shown here:

```
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
```
```
+---------+------+
| a       | b    |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+---------+------+
```

mysql> SELECT a->"$[4][1]" FROM tj10;
```
+--------+
| a->"$[4][1]" |
+--------+
| NULL   |
| 44     |
+--------+
```

2 rows in set (0.00 sec)

This is the same behavior as seen in such cases when using JSON_EXTRACT():

mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
```
| JSON_EXTRACT(a, "$[4][1]") |
+----------------------------+
| NULL                       |
| 44                         |
+----------------------------+
```

2 rows in set (0.00 sec)

- **column->>path**

This is an improved, unquoting extraction operator. Whereas the -> operator simply extracts a value, the ->> operator in addition unquotes the extracted result. In other words, given a JSON column value `column` and a path expression `path`, the following three expressions return the same value:

- `JSON_UNQUOTE(JSON_EXTRACT(column, path))`
- `JSON_UNQUOTE(column->>path)`
- `column->>path`

The ->> operator can be used wherever JSON_UNQUOTE(JSON_EXTRACT()) would be allowed. This includes (but is not limited to) SELECT lists, WHERE and HAVING clauses, and ORDER BY and GROUP BY clauses.
Functions That Search JSON Values

The next few statements demonstrate some ->> operator equivalences with other expressions in the
mysql client:
mysql> SELECT * FROM jemp WHERE g > 2;
+-------------------------------+------+
| c
| g
|
+-------------------------------+------+
| {"id": "3", "name": "Barney"} |
3 |
| {"id": "4", "name": "Betty"} |
4 |
+-------------------------------+------+
2 rows in set (0.01 sec)
mysql> SELECT c->'$.name' AS name
->
FROM jemp WHERE g > 2;
+----------+
| name
|
+----------+
| "Barney" |
| "Betty" |
+----------+
2 rows in set (0.00 sec)
mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
->
FROM jemp WHERE g > 2;
+--------+
| name
|
+--------+
| Barney |
| Betty |
+--------+
2 rows in set (0.00 sec)
mysql> SELECT c->>'$.name' AS name
->
FROM jemp WHERE g > 2;
+--------+
| name
|
+--------+
| Barney |
| Betty |
+--------+
2 rows in set (0.00 sec)

See Indexing a Generated Column to Provide a JSON Column Index, for the SQL statements used to
create and populate the jemp table in the set of examples just shown.
This operator can also be used with JSON arrays, as shown here:
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
mysql> INSERT INTO tj10 VALUES
->
('[3,10,5,"x",44]', 33),
->
('[3,10,5,17,[22,"y",66]]', 0);
Query OK, 2 rows affected (0.04 sec)
Records: 2 Duplicates: 0 Warnings: 0
mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
+-----------+--------------+
| a->"$[3]" | a->"$[4][1]" |
+-----------+--------------+
| "x"
| NULL
|
| 17
| "y"
|
+-----------+--------------+

2025


Functions That Search JSON Values

As with ->, the ->> operator is always expanded in the output of EXPLAIN, as the following example demonstrates:

```sql
mysql> EXPLAIN SELECT c->>'$.name' AS name
    -> FROM jemp WHERE g > 2\G
```

```plaintext
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
```

```
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select
json_unquote(json_extract(`jtest`.`jemp`.`c`,'$.name')) AS `name` from
`jtest`.`jemp` where (`jtest`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

This is similar to how MySQL expands the -> operator in the same circumstances.

- **JSON_KEYS**(*json_doc[, path]*)

  Returns the keys from the top-level value of a JSON object as a JSON array, or, if a *path* argument is given, the top-level keys from the selected path. Returns NULL if any argument is NULL, the *json_doc* argument is not an object, or *path*, if given, does not locate an object. An error occurs if the *json_doc* argument is not a valid JSON document or the *path* argument is not a valid path expression or contains a * or ** wildcard.

  The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.
Functions That Search JSON Values

+----------------------------------------------+
| ["c"]
|
+----------------------------------------------+

• JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])
Returns the path to the given string within a JSON document. Returns NULL if any of the json_doc,
search_str, or path arguments are NULL; no path exists within the document; or search_str is not
found. An error occurs if the json_doc argument is not a valid JSON document, any path argument is
not a valid path expression, one_or_all is not 'one' or 'all', or escape_char is not a constant
expression.
The one_or_all argument affects the search as follows:
• 'one': The search terminates after the first match and returns one path string. It is undefined which
match is considered first.
• 'all': The search returns all matching path strings such that no duplicate paths are included. If there
are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.
Within the search_str search string argument, the % and _ characters work as for the LIKE operator:
% matches any number of characters (including zero characters), and _ matches exactly one character.
To specify a literal % or _ character in the search string, precede it by the escape character. The default
is \ if the escape_char argument is missing or NULL. Otherwise, escape_char must be a constant
that is empty or one character.
For more information about matching and escape character behavior, see the description of LIKE in
Section 12.5.1, “String Comparison Functions”. For escape character handling, a difference from the
LIKE behavior is that the escape character for JSON_SEARCH() must evaluate to a constant at compile
time, not just at execution time. For example, if JSON_SEARCH() is used in a prepared statement and
the escape_char argument is supplied using a ? parameter, the parameter value might be constant at
execution time, but is not at compile time.
mysql> SET @j = '["abc", [{"k": "10"}, "def"], {"x":"abc"}, {"y":"bcd"}]';
mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'one', 'abc') |
+-------------------------------+
| "$[0]"
|
+-------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'abc') |
+-------------------------------+
| ["$[0]", "$[2].x"]
|
+-------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'ghi') |
+-------------------------------+
| NULL
|
+-------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', '10');
+------------------------------+
| JSON_SEARCH(@j, 'all', '10') |

2027


Functions That Modify JSON Values

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators * and **, see JSON Path Syntax.

12.17.4 Functions That Modify JSON Values

The functions in this section modify JSON values and return the result.

- **JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)**

  Appends values to the end of the indicated arrays within a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  If a path selects a scalar or object value, that value is autowrapped within an array and the new value is added to that array. Pairs for which the path does not identify any value in the JSON document are ignored.
Functions That Modify JSON Values

In MySQL 5.7, this function was named `JSON_APPEND()`. That name is no longer supported in MySQL 8.0.

- `JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)`

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard or does not end with an array element identifier.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.
Functions That Modify JSON Values

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same JSON_ARRAY_INSERT() call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

• JSON_INSERT(json_doc, path, val[, path, val] ...)

Inserts data into a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

• A member not present in an existing object. The member is added to the object and associated with the new value.

• A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of JSON_INSERT(), JSON_REPLACE(), and JSON_SET(), see the discussion of JSON_SET().
Functions That Modify JSON Values

mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON));
+------------------------------------------------------------------+
| JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON)) |
+------------------------------------------------------------------+
| {'a': 1, 'b': [2, 3], 'c': [true, false]}                       |
+------------------------------------------------------------------+
1 row in set (0.00 sec)

**• JSON_MERGE(json_doc, json_doc[, json_doc] ...)**

Merges two or more JSON documents. Synonym for JSON_MERGE_PRESERVE(); deprecated in MySQL 8.0.3 and subject to removal in a future release.

mysql> SELECT JSON_MERGE('[1, 2]', '[true, false]');
+---------------------------------------+
| JSON_MERGE('[1, 2]', '[true, false]') |
+---------------------------------------+
| [1, 2, true, false]                   |
+---------------------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1287
Message: 'JSON_MERGE' is deprecated and will be removed in a future release.
Please use JSON_MERGE_PRESERVE/JSON_MERGE_PATCH instead
1 row in set (0.00 sec)

For additional examples, see the entry for JSON_MERGE_PRESERVE().

**• JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)**

Performs an RFC 7396 compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

**Note**

For an explanation and example of the differences between this function and JSON_MERGE_PRESERVE(), see JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE().

**JSON_MERGE_PATCH()** performs a merge as follows:

1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.
2. If the second argument is not an object, the result of the merge is the second argument.
3. If both arguments are objects, the result of the merge is an object with the following members:
   - All members of the first object which do not have a corresponding member with the same key in the second object.
   - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON null literal.
• All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON null literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

For additional information, see Normalization, Merging, and Autowrapping of JSON Values.
Functions That Modify JSON Values

JSON_MERGE_PATCH() is supported in MySQL 8.0.3 and later.

JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(). The behavior of JSON_MERGE_PATCH() is the same as that of JSON_MERGE_PRESERVE(), with the following two exceptions:

- **JSON_MERGE_PATCH()** removes any member in the first object with a matching key in the second object, provided that the value associated with the key in the second object is not JSON null.

- If the second object has a member with a key matching a member in the first object, **JSON_MERGE_PATCH()** replaces the value in the first object with the value in the second object, whereas **JSON_MERGE_PRESERVE()** appends the second value to the first value.

This example compares the results of merging the same 3 JSON objects, each having a matching key "a", with each of these two functions:

```sql
mysql> SET @x = '{ "a": 1, "b": 2 }',
> @y = '{ "a": 3, "c": 4 }',
> @z = '{ "a": 5, "d": 6 }';
mysql> SELECT JSON_MERGE_PATCH(@x, @y, @z) AS Patch,
> JSON_MERGE_PRESERVE(@x, @y, @z) AS Preserve\G
*************************** 1. row ***************************
Patch: {"a": 5, "b": 2, "c": 4, "d": 6}
Preserve: {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}
```

- **JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)**

Merges two or more JSON documents and returns the merged result. Returns NULL if any argument is NULL. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see Normalization, Merging, and Autowrapping of JSON Values.

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

```sql
mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '[true, false]');
+--------------------------------------------+
| JSON_MERGE_PRESERVE('[1, 2]', '[true, false]') |
| [1, 2, true, false]                         |
+--------------------------------------------+```
### Functions That Modify JSON Values

This function was added in MySQL 8.0.3 as a synonym for `JSON_MERGE()`. The `JSON_MERGE()` function is now deprecated, and is subject to removal in a future release of MySQL.

This function is similar to but differs from `JSON_MERGE_PATCH()` in significant respects; see `JSON_MERGE_PATCH()` compared with `JSON_MERGE_PRESERVE()`, for more information.

- **`JSON_REMOVE(json_doc, path[, path] ...)`**

Removes data from a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or is `$` or contains a `*` or `**` wildcard.

The `path` arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.
Functions That Modify JSON Values

• **JSON_REPLACE(json_doc, path, val[, path, val] ...)**

Replaces existing values in a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the JSON_REPLACE() function and meets the conditions outlined in Partial Updates of JSON Values.

For a comparison of JSON_INSERT(), JSON_REPLACE(), and JSON_SET(), see the discussion of JSON_SET().

```sql
mysql> SET @j = '{ "a": 1, "b": [2, 3]};
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]);
+-----------------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----------------------------------------------------+
| {"a": 10, "b": [2, 3]}                              |
+-----------------------------------------------------+
```

• **JSON_SET(json_doc, path, val[, path, val] ...)**

Inserts or updates data in a JSON document and returns the result. Returns NULL if any argument is NULL or path, if given, does not locate an object. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a JSON column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the JSON_SET() function and meets the conditions outlined in Partial Updates of JSON Values.

The JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions are related:
Functions That Modify JSON Values

- **JSON_SET()** replaces existing values and adds nonexisting values.
- **JSON_INSERT()** inserts values without replacing existing values.
- **JSON_REPLACE()** replaces only existing values.

The following examples illustrate these differences, using one path that does exist in the document (\$.a) and another that does not exist (\$.c):

```sql
mysql> SET @j = '{ "a": 1, "b": [2, 3] }';
mysql> SELECT JSON_SET(@j, '\$.a', 10, '\$.c', 'true, false');
+-------------------------------------------------+
| JSON_SET(@j, '\$.a', 10, '\$.c', 'true, false') |
| {"a": 10, "b": [2, 3], "c": "true, false"} |
+-------------------------------------------------+
mysql> SELECT JSON_INSERT(@j, '\$.a', 10, '\$.c', 'true, false');
+----------------------------------------------------+
| JSON_INSERT(@j, '\$.a', 10, '\$.c', 'true, false') |
| {"a": 1, "b": [2, 3], "c": "true, false"}        |
+----------------------------------------------------+
mysql> SELECT JSON_REPLACE(@j, '\$.a', 10, '\$.c', 'true, false');
+-----------------------------------------------------+
| JSON_REPLACE(@j, '\$.a', 10, '\$.c', 'true, false') |
| {"a": 10, "b": [2, 3]}                              |
+-----------------------------------------------------+
```

- **JSON_UNQUOTE(json_val)**

Unquotes JSON value and returns the result as a utf8mb4 string. Returns NULL if the argument is NULL. An error occurs if the value starts with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the NO_BACKSLASH_ESCAPES SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the escape character. MySQL recognizes the escape sequences shown in Table 12.22, "JSON_UNQUOTE() Special Character Escape Sequences". For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B.

**Table 12.22 JSON_UNQUOTE() Special Character Escape Sequences**

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\f</td>
<td>A formfeed character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>\uXXXX</td>
<td>UTF-8 bytes for Unicode value XXXX</td>
</tr>
</tbody>
</table>

2037
Two simple examples of the use of this function are shown here:

```
mysql> SET @j = '"abc"';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-------+------------------+
| @j    | JSON_UNQUOTE(@j) |
+-------+------------------+
| "abc" | abc              |
+-------+------------------+
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----------+------------------+
| @j        | JSON_UNQUOTE(@j) |
+-----------+------------------+
| [1, 2, 3] | [1, 2, 3]        |
+-----------+------------------+
```

The following set of examples shows how JSON_UNQUOTE handles escapes with NO_BACKSLASH_ESCAPES disabled and enabled:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
| 2                           |
+------------------------------+
mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
| \t\u0032                   |
+------------------------------+
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
| 2                           |
+------------------------------+
```

12.17.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- **JSON_DEPTH(json_doc)**

  Returns the maximum depth of a JSON document. Returns NULL if the argument is NULL. An error occurs if the argument is not a valid JSON document.

  An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.
Functions That Return JSON Value Attributes

- **JSON_DEPTH(json_doc)**

  Returns the depth of a JSON value. The depth is the number of layers of arrays or objects in the JSON document.

  Returns NULL if any argument is NULL, or if the JSON document is not valid JSON.

- **JSON_LENGTH(json_doc[, path])**

  Returns the length of a JSON document, or, if a path argument is given, the length of the value within the document identified by the path. Returns NULL if any argument is NULL or the path argument does not identify a value in the document. An error occurs if the json_doc argument is not a valid JSON document or the path argument is not a valid path expression or contains a * or ** wildcard.

  The length of a document is determined as follows:

  - The length of a scalar is 1.
  - The length of an array is the number of array elements.
  - The length of an object is the number of object members.
  - The length does not count the length of nested arrays or objects.

  Returns a utf8mb4 string indicating the type of a JSON value. This can be an object, an array, or a scalar type, as shown here:
Functions That Return JSON Value Attributes

```sql
mysql> SET @j = '{{"a": [10, true]}}';
mysql> SELECT JSON_TYPE(@j);
+-------------------+
| JSON_TYPE(@j)     |
| OBJECT            |
+-------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
| ARRAY                |
+------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
| INTEGER              |
+---------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
| BOOLEAN             |
+---------------------------------------+
```

`JSON_TYPE()` returns **NULL** if the argument is **NULL**:

```sql
mysql> SELECT JSON_TYPE(NULL);
+-----------------+
| JSON_TYPE(NULL) |
| NULL            |
+-----------------+
```

An error occurs if the argument is not a valid JSON value:

```sql
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

For a non-**NULL**, non-error result, the following list describes the possible `JSON_TYPE()` return values:

- **Purely JSON types:**
  - **OBJECT**: JSON objects
  - **ARRAY**: JSON arrays
  - **BOOLEAN**: The JSON true and false literals
  - **NULL**: The JSON null literal

- **Numeric types:**
  - **INTEGER**: MySQL TINYINT, SMALLINT, MEDIUMINT and INT and BIGINT scalars
  - **DOUBLE**: MySQL DOUBLE FLOAT scalars
  - **DECIMAL**: MySQL DECIMAL and NUMERIC scalars
JSON Table Functions

• Temporal types:
• DATETIME: MySQL DATETIME and TIMESTAMP scalars
• DATE: MySQL DATE scalars
• TIME: MySQL TIME scalars
• String types:
• STRING: MySQL utf8 character type scalars: CHAR, VARCHAR, TEXT, ENUM, and SET
• Binary types:
• BLOB: MySQL binary type scalars including BINARY, VARBINARY, BLOB, and BIT
• All other types:
• OPAQUE (raw bits)
• JSON_VALID(val)
Returns 0 or 1 to indicate whether a value is valid JSON. Returns NULL if the argument is NULL.
mysql> SELECT JSON_VALID('{"a": 1}');
+------------------------+
| JSON_VALID('{"a": 1}') |
+------------------------+
|
1 |
+------------------------+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('"hello"');
+---------------------+-----------------------+
| JSON_VALID('hello') | JSON_VALID('"hello"') |
+---------------------+-----------------------+
|
0 |
1 |
+---------------------+-----------------------+

12.17.6 JSON Table Functions
This section contains information about JSON functions that convert JSON data to tabular data. In MySQL
8.0.4 and later, one such function—JSON_TABLE()—is supported.
• JSON_TABLE(expr, path COLUMNS (column_list) [AS] alias)
Extracts data from a JSON document and returns it as a relational table having the specified columns.
The complete syntax for this function is shown here:
JSON_TABLE(
expr,
path COLUMNS (column_list)
)
[AS] alias
column_list:
column[, column][, ...]
column:
name FOR ORDINALITY
| name type PATH string path [on_error] [on_empty]
| name type EXISTS PATH string path

**JSON Table Functions**

<table>
<thead>
<tr>
<th>JSON Table Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>NESTED [PATH] path COLUMNS (column_list)</td>
</tr>
</tbody>
</table>

**on_error:**

{NULL | ERROR | DEFAULT json_string} ON ERROR

**on_empty:**

{NULL | ERROR | DEFAULT json_string} ON EMPTY

**expr:** This is an expression that returns JSON data. This can be a constant ('{"a":1}'), a column (t1.json_data, given table t1 specified prior to JSON_TABLE() in the FROM clause), or a function call (JSON_EXTRACT(t1,jsn_data,'$.post.comments')).

**path:** A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the *row source*; this is used to generate a row of relational data. The *columns* clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The *alias* is required. The usual rules for table aliases apply (see Section 9.2, “Schema Object Names”).

**JSON_TABLE()** supports four types of columns, described in the following list:

1. **name FOR ORDINALITY:** This type enumerates rows in the *columns* clause; the column named *name* is a counter whose type is UNSIGNED INT, and whose initial value is 1. This is equivalent to specifying a column as AUTO_INCREMENT in a CREATE TABLE statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a NESTED [PATH] clause.

2. **name type PATH string_path [on_error] [on_empty]:** Columns of this type are used to extract values specified by *string_path.* *type* is a MySQL data type. **JSON_TABLE()** extracts data as JSON then coerces it to the column type, using the regular automatic type conversion applying to JSON data in MySQL. The exact behavior depends on the column type: If the column type is an SQL type, then only a scalar value can be saved in the column. Saving an object or array triggers the on error clause; this also occurs when an error takes place during coercion from the value saved as JSON to the table column, such as trying to save the string 'asd' to an integer column. A missing value triggers the on_empty clause.

The optional on_error clause determines what **JSON_TABLE()** does when saving an object or array:

- **NULL ON ERROR:** The column is set to NULL; this is the default behavior. If an error occurs during type coercion, a warning is thrown.
- **ERROR ON ERROR:** An error is thrown.
- **DEFAULT json_string ON ERROR:** The json_string is parsed as JSON (provided that it is valid) and stored instead of the object or array. A warning is thrown if the error is caused by type coercion. Column type rules also apply to the default value.

When a value saved to a column is truncated, such as saving 3.14159 in a DECIMAL(10,1) column, a warning is issued independently of any on error option. When multiple values are truncated in a single statement, the warning is issued only once.

The optional on empty clause determines what **JSON_TABLE()** does in the event that data is missing (depending on type). This clause is also triggered on a column in a NESTED PATH clause when the latter has no match and a NULL complemented row is produced for it. on empty takes one of the following values:
• **NULL ON EMPTY**: The column is set to **NULL**; this is the default behavior.

• **ERROR ON EMPTY**: An error is thrown.

• **DEFAULT json_string ON EMPTY**: the provided `json_string` is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.

This query demonstrates the use of the **ON ERROR** and **ON EMPTY** options. The row corresponding to `{"b":1}` is empty for the path `"$.a"`, and attempting to save `[1,2]` as a scalar produces an error; these rows are highlighted in the output shown.

```sql
mysql> SELECT *
  -> FROM
  -> JSON_TABLE(
  ->  '[{"a":"3"},{"a":2},{"b":1},{"a":0},{"a":[1,2]}]',
  ->  "$[*]"
  -> COLUMNS(
  ->  rowid FOR ORDINALITY,
  ->  ac VARCHAR(100) PATH "$a" DEFAULT '999' ON ERROR DEFAULT '111' ON EMPTY,
  ->  aj JSON PATH "$a" DEFAULT '{"x": 333}' ON EMPTY,
  ->  bx INT EXISTS PATH "$b"
  -> )
  -> ) AS tt;
```

<table>
<thead>
<tr>
<th>rowid</th>
<th>ac</th>
<th>aj</th>
<th>bx</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>&quot;3&quot;</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>111</td>
<td>{&quot;x&quot;: 333}</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>999</td>
<td>[1, 2]</td>
<td>0</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

3. **name type EXISTS PATH path**: This column returns 1 if any data is present at the location specified by `path`, and 0 otherwise. **type** can be any valid MySQL data type, but should normally be specified as some variety of **INT**.

4. **NESTED [PATH] path COLUMNS (column_list)**: This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple **PATH** options allows projection of JSON values from multiple levels of nesting into a single row.

The `path` is relative to the parent path row path of `JSON_TABLE()`), or the path of the parent **NESTED [PATH]** clause in the event of nested paths.

Column names are subject to the usual rules and limitations governing table column names. See Section 9.2, “Schema Object Names”.

All JSON and JSON path expressions are checked for validity; an invalid expression of either type causes an error.

Each match for the `path` preceding the **COLUMNS** keyword maps to an individual row in the result table. For example, the following query gives the result shown here:

```sql
mysql> SELECT *
```

2043
The expression "$[*]" matches each element of the array. You can filter the rows in the result by modifying the path; for example, using "$[1]" limits extraction to the second element of the JSON array used as the source, as shown here:

```sql
mysql> SELECT *
    -> FROM
    -> JSON_TABLE(
    ->   '[["x":2,"y":"8"],{"x":"3","y":"7"},{"x":"4","y":6}]',
    ->   "$[*]" COLUMNS(
    ->     xval VARCHAR(100) PATH "$x",
    ->     yval VARCHAR(100) PATH "$y"
    -> )
    -> ) AS jt1;
```

<table>
<thead>
<tr>
<th>xval</th>
<th>yval</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>

Within a column definition, "$" passes the entire match to the column; "$x" and "$y" pass only the values corresponding to the keys x and y, respectively, within that match. For more information, see JSON Path Syntax.

NESTED PATH (or simply NESTED; PATH is optional) produces a set of records for each match in the COLUMNS clause to which it belongs. If there is no match, all columns of the nested path are set to NULL. This implements an outer join between the topmost clause and NESTED [PATH]. An inner join can be emulated by applying a suitable condition in the WHERE clause, as shown here:

```sql
mysql> SELECT *
    -> FROM
    -> JSON_TABLE(
    ->   '[["a": 1, "b": [11,111]}, {"a": 2, "b": [22,222]}, {"a":3}]',
    ->   "$[*]" COLUMNS("a" INT PATH '$.a',
    ->   NESTED PATH '$.b[*]' COLUMNS (b INT PATH '$'))
    -> ) AS jt
    -> WHERE b IS NOT NULL;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11</td>
</tr>
<tr>
<td>1</td>
<td>111</td>
</tr>
</tbody>
</table>
Sibling nested paths—that is, two or more instances of `NESTED [PATH]` in the same `COLUMNS` clause—are processed one after another, one at a time. While one nested path is producing records, columns of any sibling nested path expressions are set to `NULL`. This means that the total number of records for a single match within a single containing `COLUMNS` clause is the sum and not the product of all records produced by `NESTED [PATH]` modifiers, as shown here:

```sql
mysql> SELECT * -> FROM -> JSON_TABLE(  -> '[["a": 1, "b": [11,111]],{"a": 2, "b": [22,222]]}',  -> '{$[*]}' COLUMNS(  -> a INT PATH '$.a',  -> NESTED PATH '$.b[*]' COLUMNS (b1 INT PATH '$'),  -> NESTED PATH '$.b[*]' COLUMNS (b2 INT PATH '$')  -> )  -> ) AS jt;
        +------+------+------+
        | a    | b1   | b2   |
        +------+------+------+
        | 1    | 11   | NULL |
        | 1    | 111  | NULL |
        | 1    | NULL | 111  |
        | 1    | NULL | 22   |
        | 2    | 22   | NULL |
        | 2    | NULL | 22   |
        +------+------+------+
```

An `FOR ORDINALITY` column enumerates records produced by the `COLUMNS` clause, and can be used to distinguish parent records of a nested path, especially if values in parent records are the same, as can be seen here:

```sql
mysql> SELECT * -> FROM -> JSON_TABLE("  -> '"a": "a_val",  -> 'b": "b": [("c": "c_val", "l": [1,2]])},  -> '{$[*]}' COLUMNS(  -> top_ord FOR ORDINALITY,  -> apath VARCHAR(10) PATH '$.a',  -> NESTED PATH '$.b[*]' COLUMNS (  -> bpath VARCHAR(10) PATH '$.c',  -> ord FOR ORDINALITY,  -> NESTED PATH '$.l[*]' COLUMNS (lpath VARCHAR(10) PATH '$'))  -> )  -> ) AS jt;
        +---------+---------+---------+------+-------+
        | top_ord | apath   | bpath   | ord  | lpath |
        +---------+---------+---------+------+-------+
        | 1       | a_val   | c_val   | 1    | 1     |
        | 1       | a_val   | c_val   | 1    | 2     |
        | 2       | a_val   | c_val   | 1    | 11    |
        | 2       | a_val   | c_val   | 2    | 22    |
        +---------+---------+---------+------+-------+
```
The source document contains an array of two elements; each of these elements produces two rows. The values of `apath` and `bpath` are the same over the entire result set; this means that they cannot be used to determine whether `lpath` values came from the same or different parents. The value of the `ord` column remains the same as the set of records having `top_ord` equal to 1, so these two values are from a single object. The remaining two values are from different objects, since they have different values in the `ord` column.

12.17.7 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. `JSON_PRETTY()` prints out a JSON value in a format that is easy to read. `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()` show, respectively, the amount of storage space used by a given JSON value and the amount of space remaining in a JSON column following a partial update.

- **`JSON_PRETTY(json_val)`**

  Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a `NULL` value, the function returns `NULL`. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

  Formatting of the output from this function adheres to the following rules:
  
  - Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.
  - Each level of indentation adds two leading spaces.
  - A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.
  - The key and the value of an object member are separated by a colon followed by a space (`:`).
  - An empty object or array is printed on a single line. No space is printed between the opening and closing brace.
  - Special characters in string scalars and key names are escaped employing the same rules used by the `JSON_QUOTE()` function.

```sql
mysql> SELECT JSON_PRETTY('123'); # scalar
+--------------------+
| JSON_PRETTY('123') |
+--------------------+
| 123                |
+--------------------+

mysql> SELECT JSON_PRETTY('[1,3,5]'); # array
+------------------------+
| JSON_PRETTY('[1,3,5]') |
+------------------------+
| [1, 3, 5]             |
+------------------------+
```
• **JSON_STORAGE_FREE(json_val)**

For a JSON column value, this function shows how much storage space was freed in its binary representation after it was updated in place using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The argument can also be a valid JSON document or a string which can be parsed as one—either as a literal value or as the value of a user variable—in which case the function returns 0. It returns a positive, nonzero value if the argument is a JSON column value which has been updated as described previously, such that its binary representation takes up less space than it did prior to the update. For a JSON column which has been updated such that its binary representation is the same as or larger than before, or if the update was not able to take advantage of a partial update, it returns 0; it returns **NULL** if the argument is **NULL**.

If `json_val` is not **NULL**, and neither is a valid JSON document nor can be successfully parsed as one, an error results.

In this example, we create a table containing a JSON column, then insert a row containing a JSON object:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.38 sec)

mysql> INSERT INTO jtable VALUES
```
Now we update the column value using JSON_SET() such that a partial update can be performed; in this case, we replace the value pointed to by the c key (the array [true, false]) with one that takes up less space (the integer 1):

```
mysql> UPDATE jtable
    > SET jcol = JSON_SET(jcol, ".a", 10, ".b", "wxyz", ".c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```
```
mysql> SELECT * FROM jtable;
+----------------------------------+
<table>
<thead>
<tr>
<th>jcol</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 10, &quot;b&quot;: &quot;wxyz&quot;, &quot;c&quot;: 1}</td>
</tr>
</tbody>
</table>
+----------------------------------+
1 row in set (0.00 sec)
```

The effects of successive partial updates on this free space are cumulative, as shown in this example using JSON_SET() to reduce the space taken up by the value having key b (and making no other changes):

```
mysql> UPDATE jtable
    > SET jcol = JSON_SET(jcol, ".a", 10, ".b", "wx", ".c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```
```
mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-------------------------+
<table>
<thead>
<tr>
<th>JSON_STORAGE_FREE(jcol)</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
</tr>
</tbody>
</table>
+-------------------------+
1 row in set (0.00 sec)
```

Updating the column without using JSON_SET(), JSON_REPLACE(), or JSON_REMOVE() means that the optimizer cannot perform the update in place; in this case, JSON_STORAGE_FREE() returns 0, as shown here:

```
mysql> UPDATE jtable SET jcol = '{"a": 10, "b": 1}';
Query OK, 1 row affected (0.05 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```
```
mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-------------------------+
<table>
<thead>
<tr>
<th>JSON_STORAGE_FREE(jcol)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-------------------------+
1 row in set (0.00 sec)
```
Partial updates of JSON documents can be performed only on column values. For a user variable that stores a JSON value, the value is always completely replaced, even when the update is performed using `JSON_SET()`:

```sql
mysql> SET @j = '{"a": 10, "b": "wxyz", "c": 
"[true, false]"}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$.a', 10, '$.b', 'wxyz', '$.c', '1');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_FREE(@j) AS Free;
+----------------------------------+------+
<table>
<thead>
<tr>
<th>@j</th>
<th>Free</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 10, &quot;b&quot;: &quot;wxyz&quot;, &quot;c&quot;: &quot;1&quot;}</td>
<td>0</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>------</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns 0:

```sql
mysql> SELECT JSON_STORAGE_FREE('{"a": 10, "b": 
"wxyz", "c": "1"}') AS Free;
+------+
<table>
<thead>
<tr>
<th>Free</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>------</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```

- **JSON_STORAGE_SIZE(json_val)**

  This function returns the number of bytes used to store the binary representation of a JSON document. When the argument is a JSON column, this is the space used to store the JSON document as it was inserted into the column, prior to any partial updates that may have been performed on it afterwards. `json_val` must be a valid JSON document or a string which can be parsed as one. In the case where it is string, the function returns the amount of storage space in the JSON binary representation that is created by parsing the string as JSON and converting it to binary. It returns `NULL` if the argument is `NULL`.

  An error results when `json_val` is not `NULL`, and is not—or cannot be successfully parsed as—a JSON document.

  To illustrate this function's behavior when used with a JSON column as its argument, we create a table named `jtable` containing a JSON column `jcol`, insert a JSON value into the table, then obtain the storage space used by this column with `JSON_STORAGE_SIZE()`, as shown here:

```sql
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO jtable VALUES
-> ('{"a": 1000, "b": "wxyz", "c": 
"[1, 3, 5, 7]"}');
Query OK, 1 row affected (0.04 sec)

mysql> SELECT
```
According to the output of `JSON_STORAGE_SIZE()`, the JSON document inserted into the column takes up 47 bytes. We also checked the amount of space freed by any previous partial updates of the column using `JSON_STORAGE_FREE()`; since no updates have yet been performed, this is 0, as expected.

Next we perform an UPDATE on the table that should result in a partial update of the document stored in `jcol`, and then test the result as shown here:

```
mysql> UPDATE jtable SET jcol = 
  -> JSON_SET(jcol, 
  -> "$.b", "a");
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT 
  -> jcol, 
  -> JSON_STORAGE_SIZE(jcol) AS Size, 
  -> JSON_STORAGE_FREE(jcol) AS Free 
  -> FROM jtable;
+------------------------------------------------+------+------+
| jcol                                           | Size | Free |
+------------------------------------------------+------+------+
| {"a": 1000, "b": "a", "c": "[1, 3, 5, 7]"}   | 47   | 3    |
+------------------------------------------------+------+------+
1 row in set (0.00 sec)
```

The value returned by `JSON_STORAGE_FREE()` in the previous query indicates that a partial update of the JSON document was performed, and that this freed 3 bytes of space used to store it. The result returned by `JSON_STORAGE_SIZE()` is unchanged by the partial update.

Partial updates are supported for updates using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The direct assignment of a value to a JSON column cannot be partially updated; following such an update, `JSON_STORAGE_SIZE()` always shows the storage used for the newly-set value:

```
mysql> UPDATE jtable 
mysql> SET jcol = '{"a": 4.55, "b": "wxyz", "c": 
  -> "[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT 
  -> jcol, 
  -> JSON_STORAGE_SIZE(jcol) AS Size, 
  -> JSON_STORAGE_FREE(jcol) AS Free 
  -> FROM jtable;
+------------------------------------------------+------+------+
| jcol                                           | Size | Free |
+------------------------------------------------+------+------+
| {"a": 4.55, "b": "wxyz", "c": "[true, false]"} | 56   | 0    |
+------------------------------------------------+------+------+
1 row in set (0.00 sec)
```
A JSON user variable cannot be partially updated. This means that this function always shows the space currently used to store a JSON document in a user variable:

```sql
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+------------------------------------+------+
| @j                                 | Size |
+------------------------------------+------+
| [100, "sakila", [1, 3, 5], 425.05] | 45   |
+------------------------------------+------+
1 row in set (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+----------------------------------+------+
| @j                               | Size |
+----------------------------------+------+
| [100, "json", [1, 3, 5], 425.05] | 43   |
+----------------------------------+------+
1 row in set (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$[2][0]', JSON_ARRAY(10, 20, 30));
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+---------------------------------------------+------+
| @j                                          | Size |
+---------------------------------------------+------+
| [100, "json", [[10, 20, 30], 3, 5], 425.05] | 56   |
+---------------------------------------------+------+
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns the current storage space used:

```sql
mysql> SELECT
    -> JSON_STORAGE_SIZE('[100, "sakila", [1, 3, 5], 425.05]') AS A,
    -> JSON_STORAGE_SIZE('{"a": 1000, "b": "a", "c": "[1, 3, 5, 7]"}') AS B,
    -> JSON_STORAGE_SIZE('{"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}') AS C,
    -> JSON_STORAGE_SIZE('[100, "json", [[10, 20, 30], 3, 5], 425.05]') AS D;
+----+----+----+----+
| A  | B  | C  | D  |
|----+----+----+----|
| 45 | 44 | 47 | 56 |
+----+----+----+----+
1 row in set (0.00 sec)
```

12.18 Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See GTID Sets for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:
## Functions Used with Global Transaction Identifiers (GTIDs)

### CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1,',',g2);

For more information about GTIDs and how these GTID functions are used in practice, see Section 17.1.3, "Replication with Global Transaction Identifiers".

### Table 12.23 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTID_SUBSET()</td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
</tr>
<tr>
<td>GTID_SUBTRACT()</td>
<td>Return all GTIDs in set that are not in subset.</td>
</tr>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET()</td>
<td>Wait until the given GTIDs have executed on slave.</td>
</tr>
<tr>
<td>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS</td>
<td>Wait until the given GTIDs have executed on slave.</td>
</tr>
</tbody>
</table>

- **GTID_SUBSET(set1,set2)**

  Given two sets of global transaction identifiers `set1` and `set2`, returns true if all GTIDs in `set1` are also in `set2`. Returns false otherwise.

  The GTID sets used with this function are represented as strings, as shown in the following examples:

  ```sql
  mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
  *************************** 1. row ***************************
  GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
  1 row in set (0.00 sec)
  
  mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
  *************************** 1. row ***************************
  GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
  1 row in set (0.00 sec)
  
  mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
                           '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
  *************************** 1. row ***************************
  GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 0
  1 row in set (0.00 sec)
  
- **GTID_SUBTRACT(set1,set2)**

  Given two sets of global transaction identifiers `set1` and `set2`, returns only those GTIDs from `set1` that are not in `set2`.

  All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

  ```sql
  mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                                '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
  *************************** 1. row ***************************
  GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
  1 row in set (0.00 sec)
  ```
Functions Used with Global Transaction Identifiers (GTIDs)

```sql
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                             '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')
                                 -> GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                                1 row in set (0.00 sec)
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                             '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')
                                 -> GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                                1 row in set (0.01 sec)
```

- **WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])**

  Wait until the server has applied all of the transactions whose global transaction identifiers are contained in **gtid_set**; that is, until the condition `GTID_SUBSET(gtid_subset, @@GLOBAL.gtid_executed)` holds. See Section 17.1.3.1, “GTID Format and Storage” for a definition of GTID sets.

  If a timeout is specified, and `timeout` seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. `timeout` is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied.

  ```sql
  WAIT_FOR_EXECUTED_GTID_SET() monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.
  
  For more information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.
  
  GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:
  ```
  ```sql
  mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
          -> 0
  ```
  For a syntax description for GTID sets, see Section 17.1.3.1, “GTID Format and Storage”.

  For **WAIT_FOR_EXECUTED_GTID_SET()**, the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

  `gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

- **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][, channel])**

  ```sql
  WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() is similar to WAIT_FOR_EXECUTED_GTID_SET() in that it waits until all of the transactions whose global transaction identifiers are contained in **gtid_set** have been applied, or until `timeout` seconds have elapsed, whichever occurs first. However, WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() applies to a specific replication channel, and stops only after the transactions have been applied on the specified channel, for which the applier must be running. In contrast, WAIT_FOR_EXECUTED_GTID_SET() stops after the transactions have been applied, regardless of where they were applied (on any replication channel or any user client), and whether or not any replication channels are running.

  The `channel` option names which replication channel the function applies to. If no channel is named and no channels other than the default replication channel exist, the function applies to the default replication channel. If multiple replication channels exist, you must specify a channel as otherwise it is
MySQL Enterprise Encryption Functions

not known which replication channel the function applies to. See Section 17.2.3, “Replication Channels” for more information on replication channels.

**Note**

Because `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` applies to a specific replication channel, if an expected transaction arrives on a different replication channel or from a user client, for example in a failover or manual recovery situation, the function can hang indefinitely if no timeout is set. Use `WAIT_FOR_EXECUTED_GTID_SET()` instead to ensure correct handling of transactions in these situations.

GTID sets used with `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` are represented as strings and must be quoted in the same way as for `WAIT_FOR_EXECUTED_GTID_SET()`. For `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`, the return value for the function is an arbitrary positive number. If GTID-based replication is not active (that is, if the value of the `gtid_mode` variable is OFF), then this value is undefined and `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` returns NULL. If the slave is not running then the function also returns NULL.

`gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

12.19 MySQL Enterprise Encryption Functions

**Note**

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, https://www.mysql.com/products/.

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

MySQL Enterprise Encryption supports the RSA, DSA, and DH cryptographic algorithms.

MySQL Enterprise Encryption is supplied as a user-defined function (UDF) library, from which individual functions can be installed individually.

12.19.1 MySQL Enterprise Encryption Installation

MySQL Enterprise Encryption functions are located in a user-defined function (UDF) library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The UDF library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements (adjust the file name suffix as necessary):
CREATE FUNCTION asymmetric_decrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING
  SONAME 'openssl_udf.so';

Once installed, UDFs remain installed across server restarts. To unload UDFs, use the `DROP FUNCTION` statement. For example, to unload the key-generation functions, do this:

DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;

In the `CREATE FUNCTION` and `DROP FUNCTION` statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The `CREATE FUNCTION` and `DROP FUNCTION` statements require the `INSERT` and `DROP` privilege, respectively, for the `mysql` database.

12.19.2 MySQL Enterprise Encryption Usage and Examples

To use MySQL Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks:

- Create a private/public key pair using RSA encryption
- Use the private key to encrypt data and the public key to decrypt it
- Generate a digest from a string
- Use the digest with a key pair
- Create a symmetric key
- Limit CPU usage by key-generation operations

Create a private/public key pair using RSA encryption

```sql
-- Encryption algorithm; can be 'DSA' or 'DH' instead
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 1024;

-- Create private key
SET @priv = CREATE_ASYM_METRIC_PRIV_KEY(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = CREATE_ASYM_METRIC_PUB_KEY(@algo, @priv);
```
Now you can use the key pair to encrypt and decrypt data, sign and verify data, or generate symmetric keys.

**Use the private key to encrypt data and the public key to decrypt it**

This requires that the members of the key pair be RSA keys.

```sql
SET @ciphertext = ASYMMETRIC_ENCRYPT(@algo, 'My secret text', @priv);
SET @cleartext = ASYMMETRIC_Decrypt(@algo, @ciphertext, @pub);
```

Conversely, you can encrypt using the public key and decrypt using the private key.

```sql
SET @ciphertext = ASYMMETRIC_ENCRYPT(@algo, 'My secret text', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT(@algo, @ciphertext, @priv);
```

In either case, the algorithm specified for the encryption and decryption functions must match that used to generate the keys.

**Generate a digest from a string**

```sql
-- Digest type; can be 'SHA256', 'SHA384', or 'SHA512' instead
SET @dig_type = 'SHA224';
-- Generate digest string
SET @dig = CREATE_DIGEST(@dig_type, 'My text to digest');
```

**Use the digest with a key pair**

The key pair can be used to sign data, then verify that the signature matches the digest.

```sql
-- Encryption algorithm; could be 'DSA' instead; keys must
-- have been created using same algorithm
SET @algo = 'RSA';
-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

**Create a symmetric key**

This requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to `CREATE_DH_PARAMETERS()`, then pass the secret as the “key length” to `CREATEASYMMETRIC_PRIV_KEY()`.

```sql
-- Generate DH shared symmetric secret
SET @dhp = CREATE_DH_PARAMETERS(1024);
-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = CREATEASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub1 = CREATEASYMMETRIC_PUB_KEY(@algo, @priv1);
SET @priv2 = CREATEASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub2 = CREATEASYMMETRIC_PUB_KEY(@algo, @priv2);
-- Generate symmetric key using public key of first party,
-- private key of second party
SET @sym1 = ASYMMETRIC_DERIVE(@pub1, @priv2);
-- Or use public key of second party, private key of first party
```
SET @sym2 = ASYMMETRIC_DERIVE(@pub2, @priv1);

Key string values can be created at runtime and stored into a variable or table using `SET`, `SELECT`, or `INSERT`:

```
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SELECT CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024) INTO @priv2;
INSERT INTO t (key_col) VALUES(CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024));
```

Key string values stored in files can be read using the `LOAD_FILE()` function by users who have the `FILE` privilege.

Digest and signature strings can be handled similarly.

**Limit CPU usage by key-generation operations**

The `CREATE_ASYMMETRIC_PRIV_KEY()` and `CREATE_DH_PARAMETERS()` encryption functions take a key-length parameter, and the amount of CPU resources required by these functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

OpenSSL imposes a minimum key length of 1,024 bits for all keys. OpenSSL also imposes a maximum key length of 10,000 bits and 16,384 bits for DSA and RSA keys, respectively, for `CREATE_ASYMMETRIC_PRIV_KEY()`, and a maximum key length of 10,000 bits for `CREATE_DH_PARAMETERS()`. If those maximum values are too high, three environment variables are available to enable MySQL server administrators to set lower maximum lengths for key generation, and thereby to limit CPU usage:

- `MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD`: Maximum DSA key length in bits for `CREATE_ASYMMETRIC_PRIV_KEY()`. The minimum and maximum values for this variable are 1,024 and 10,000.
- `MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD`: Maximum RSA key length in bits for `CREATE_ASYMMETRIC_PRIV_KEY()`. The minimum and maximum values for this variable are 1,024 and 16,384.
- `MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD`: Maximum key length in bits for `CREATE_DH_PARAMETERS()`. The minimum and maximum values for this variable are 1,024 and 10,000.

To use any of these environment variables, set them in the environment of the process that starts the server. If set, their values take precedence over the maximum key lengths imposed by OpenSSL. For example, to set a maximum key length of 4,096 bits for DSA and RSA keys for `CREATE_ASYMMETRIC_PRIV_KEY()`, set these variables:

```
export MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD=4096
export MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD=4096
```

The example uses Bourne shell syntax. The syntax for other shells may differ.

### 12.19.3 MySQL Enterprise Encryption Function Reference

**Table 12.24 MySQL Enterprise Encryption Functions**

</tbody>
</table>
### 12.19.4 MySQL Enterprise Encryption Function Descriptions

MySQL Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.

- If the arguments are not suitable to permit a function to perform the requested operation, it returns `NULL` or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key. (OpenSSL imposes its own key-length limits, and server administrators can impose additional limits on maximum key length by setting environment variables. See Section 12.19.2, "MySQL Enterprise Encryption Usage and Examples".)

- The underlying SSL library takes care of randomness initialization.

Several of the functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

#### Table 12.25 Supported Algorithms by Function

**Note**

Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other functions that take key arguments might accept only certain types of keys. For example, `ASYMMETRIC_ENCRYPT()` and `ASYMMETRIC_DECRYPT()` accept only RSA keys.

The following descriptions describe the calling sequences for MySQL Enterprise Encryption functions. For additional examples and discussion, see Section 12.19.2, "MySQL Enterprise Encryption Usage and Examples".

- `ASYMMETRIC_DECRYPT(algorithm, crypt_str, key_str)`
Decrypts an encrypted string using the given algorithm and key string, and returns the resulting cleartext as a binary string. If decryption fails, the result is \texttt{NULL}.

\texttt{key\_str} must be a valid key string in PEM format. For successful decryption, it must be the public or private key string corresponding to the private or public key string used with \texttt{ASYMMETRIC\_ENCRYPT()} to produce the encrypted string. \texttt{algorithm} indicates the encryption algorithm used to create the key.

Supported \texttt{algorithm} values: \texttt{'RSA'}

For a usage example, see the description of \texttt{ASYMMETRIC\_ENCRYPT()}.

- \texttt{ASYMMETRIC\_DERIVE(pub\_key\_str, priv\_key\_str)}

Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is \texttt{NULL}.

\texttt{pub\_key\_str} and \texttt{priv\_key\_str} must be valid key strings in PEM format. They must be created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

\begin{verbatim}
SET @dhp = CREATE_DH_PARAMETERS(1024);
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv2);
\end{verbatim}

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

\begin{verbatim}
ASYMMETRIC\_DERIVE(@pub1, @priv2) = ASYMMETRIC\_DERIVE(@pub2, @priv1)
\end{verbatim}

- \texttt{ASYMMETRIC\_ENCRYPT(algorithm, str, key\_str)}

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is \texttt{NULL}.

The \texttt{str} length cannot be greater than the \texttt{key\_str} length \(-\) 11, in bytes

\texttt{key\_str} must be a valid key string in PEM format. \texttt{algorithm} indicates the encryption algorithm used to create the key.

Supported \texttt{algorithm} values: \texttt{'RSA'}

To encrypt a string, pass a private or public key string to \texttt{ASYMMETRIC\_ENCRYPT()}. To recover the original unencrypted string, pass the encrypted string to \texttt{ASYMMETRIC\_DECRYPT()}, along with the public or private key string corresponding to the private or public key string used for encryption.

\begin{verbatim}
-- Generate private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('RSA', @priv);

-- Encrypt using private key, decrypt using public key
SET @ciphertext = ASYMMETRIC\_ENCRYPT('RSA', 'The quick brown fox', @priv);
SET @cleartext = ASYMMETRIC\_DECRYPT('RSA', @ciphertext, @pub);

-- Encrypt using public key, decrypt using private key
\end{verbatim}
Suppose that:

```sql
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @priv);
```

Then these identity relationships hold:

```sql
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @priv), @pub) = @s
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @pub), @priv) = @s
```

- **ASYMMETRIC_SIGN(algorithm, digest_str, priv_key_str, digest_type)**

  Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is NULL.

  - `digest_str` is the digest string. It can be generated by calling `CREATE_DIGEST()`. `digest_type` indicates the digest algorithm used to generate the digest string.
  - `priv_key_str` is the private key string to use for signing the digest string. It must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

  Supported `algorithm` values: 'RSA', 'DSA'

  Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

  For a usage example, see the description of **ASYMMETRIC_VERIFY()**.

- **ASYMMETRIC_VERIFY(algorithm, digest_str, sig_str, pub_key_str, digest_type)**

  Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed.

  - `digest_str` is the digest string. It can be generated by calling `CREATE_DIGEST()`. `digest_type` indicates the digest algorithm used to generate the digest string.
  - `sig_str` is the signature string. It can be generated by calling `ASYMMETRIC_SIGN()`.
  - `pub_key_str` is the public key string of the signer. It corresponds to the private key passed to `ASYMMETRIC_SIGN()` to generate the signature string and must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

  Supported `algorithm` values: 'RSA', 'DSA'

  Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```sql
-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA224';

-- Create private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY(@algo, 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv);

-- Generate digest from string
SET @dig = CREATE_DIGEST(@dig_type, 'The quick brown fox');

-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);

• CREATE ASYMMETRIC_PRIV_KEY(algorithm, {key_len|dh_secret})

Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. If key generation fails, the result is NULL.

Supported algorithm values: 'RSA', 'DSA', 'DH'

Supported key_len values: The minimum key length in bits is 1,024. The maximum key length depends on the algorithm: 16,384 for RSA and 10,000 for DSA. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See Section 12.19.2, “MySQL Enterprise Encryption Usage and Examples”.

For DH keys, pass a shared DH secret instead of a key length. To create the secret, pass the key length to CREATE_DH_PARAMETERS().

This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('DSA', 2048);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('DSA', @priv);

For an example showing DH key generation, see the description of ASYMMETRIC_DERIVE().

Some general considerations in choosing key lengths and encryption algorithms:

• The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.

• Generation of DH keys takes much longer than RSA or RSA keys.

• Asymmetric encryption functions are slower than symmetric functions. If performance is an important factor and the functions are to be used very frequently, you are better off using symmetric encryption. For example, consider using AES_ENCRYPT() and AES_DECRYPT().

• CREATE_ASYMMETRIC_PUB_KEY(algorithm, priv_key_str)

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. If key derivation fails, the result is NULL.

priv_key_str must be a valid key string in PEM format. algorithm indicates the encryption algorithm used to create the key.

Supported algorithm values: 'RSA', 'DSA', 'DH'

For a usage example, see the description of CREATE_ASYMMETRIC_PRIV_KEY().

• CREATE_DH_PARAMETERS(key_len)

Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to CREATE_ASYMMETRIC_PRIV_KEY(). If secret generation fails, the result is null.

Supported key_len values: The minimum and maximum key lengths in bits are 1,024 and 10,000. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose
additional limits on maximum key length by setting environment variables. See Section 12.19.2, “MySQL Enterprise Encryption Usage and Examples”.

For an example showing how to use the return value for generating symmetric keys, see the description of `ASYMMETRIC_DERIVE()`.

```sql
SET @dhp = CREATE_DH_PARAMETERS(1024);
```

- `CREATE_DIGEST(digest_type, str)`

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is `NULL`.

Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```sql
SET @dig = CREATE_DIGEST('SHA512', 'The quick brown fox');
```

The resulting digest string is suitable for use with `ASYMMETRIC_SIGN()` and `ASYMMETRIC_VERIFY()`.

### 12.20 Aggregate (GROUP BY) Functions

#### 12.20.1 Aggregate (GROUP BY) Function Descriptions

This section describes group (aggregate) functions that operate on sets of values.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td>BIT_AND()</td>
<td>Return bitwise AND</td>
</tr>
<tr>
<td>BIT_OR()</td>
<td>Return bitwise OR</td>
</tr>
<tr>
<td>BIT_XOR()</td>
<td>Return bitwise XOR</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>JSON_ARRAYAGG()</td>
<td>Return result set as a single JSON array</td>
</tr>
<tr>
<td>JSON_OBJECTAGG()</td>
<td>Return result set as a single JSON object</td>
</tr>
<tr>
<td>MAX()</td>
<td>Return the maximum value</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>STD()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_POP()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_SAMP()</td>
<td>Return the sample standard deviation</td>
</tr>
<tr>
<td>SUM()</td>
<td>Return the sum</td>

<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
</tbody>
</table>
Unless otherwise stated, group functions ignore **NULL** values.

If you use a group function in a statement containing no **GROUP BY** clause, it is equivalent to grouping on all rows. For more information, see Section 12.20.3, "MySQL Handling of GROUP BY".

Most aggregate functions can be used as window functions. Those that can be used this way are signified in their syntax description by `[over_clause]`, representing an optional **OVER** clause. **over_clause** is described in Section 12.21.2, "Window Function Concepts and Syntax", which also includes other information about window function usage.

For numeric arguments, the variance and standard deviation functions return a **DOUBLE** value. The **SUM()** and **AVG()** functions return a **DECIMAL** value for exact-value arguments (integer or **DECIMAL**), and a **DOUBLE** value for approximate-value arguments (**FLOAT** or **DOUBLE**).

The **SUM()** and **AVG()** aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as **SUM()** or **AVG()** that expect a numeric argument cast the argument to a number if necessary. For **SET** or **ENUM** values, the cast operation causes the underlying numeric value to be used.

The **BIT_AND()**, **BIT_OR()**, and **BIT_XOR()** aggregate functions perform bit operations. Prior to MySQL 8.0, bit functions and operators required **BIGINT** (64-bit integer) arguments and returned **BIGINT** values, so they had a maximum range of 64 bits. Non-**BIGINT** arguments were converted to **BIGINT** prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (**BINARY**, **VARBINARY**, and the **BLOB** types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. For discussion about argument evaluation and result types for bit operations, see the introductory discussion in Section 12.12, "Bit Functions and Operators".

- **AVG([DISTINCT] expr) [over_clause]**

  Returns the average value of **expr**. The **DISTINCT** option can be used to return the average of the distinct values of **expr**.

  If there are no matching rows, **AVG()** returns **NULL**.

  This function executes as a window function if **over_clause** is present. **over_clause** is as described in Section 12.21.2, "Window Function Concepts and Syntax"; it cannot be used with **DISTINCT**.

- **BIT_AND(expr) [over_clause]**

  Returns the bitwise **AND** of all bits in **expr**.

  The result type depends on whether the function argument values are evaluated as binary strings or numbers:
• Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

• Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. If the argument size exceeds 511 bytes, an ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, BIT_AND() returns a neutral value (all bits set to 1) having the same length as the argument values.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

As of MySQL 8.0.12, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

• BIT_OR(expr) [over_clause]

Returns the bitwise OR of all bits in expr.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

• Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

• Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. If the argument size exceeds 511 bytes, an ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, BIT_OR() returns a neutral value (all bits set to 0) having the same length as the argument values.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

As of MySQL 8.0.12, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

• BIT_XOR(expr) [over_clause]

Returns the bitwise XOR of all bits in expr.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:
Aggregate (GROUP BY) Function Descriptions

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or NULL literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.

- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an ER_INVALID_BITWISE_OPERANDS_SIZE error occurs. If the argument size exceeds 511 bytes, an ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, BIT_XOR() returns a neutral value (all bits set to 0) having the same length as the argument values.

NULL values do not affect the result unless all values are NULL. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in Section 12.12, “Bit Functions and Operators”.

As of MySQL 8.0.12, this function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- COUNT(expr) [over_clause]

Returns a count of the number of non-NUL values of expr in the rows retrieved by a SELECT statement. The result is a BIGINT value.

If there are no matching rows, COUNT() returns 0.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

mysql> SELECT student.student_name,COUNT(*) FROM student,course WHERE student.student_id=course.student_id GROUP BY student_name;

COUNT(*) is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

For transactional storage engines such as InnoDB, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, SELECT COUNT(*) statements only count rows visible to the current transaction.

As of MySQL 8.0.13, SELECT COUNT(*) FROM tbl_name query performance for InnoDB tables is optimized for single-threaded workloads if there are no extra clauses such as WHERE or GROUP BY.

InnoDB processes SELECT COUNT(*) statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, InnoDB processes SELECT COUNT(*) statements by scanning the clustered index.

Processing SELECT COUNT(*) statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of
concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

**InnoDB** handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For **MyISAM** tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```sql
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to **MyISAM** tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

- **`COUNT(DISTINCT expr,[expr...])`**

Returns a count of the number of rows with different non-NULL `expr` values.

If there are no matching rows, `COUNT(DISTINCT)` returns `0`.

```sql
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- **`GROUP_CONCAT(expr)`**

This function returns a string result with the concatenated non-NULL `expr` values from a group. It returns `NULL` if there are no non-NULL values. The full syntax is as follows:

```sql
GROUP_CONCAT([DISTINCT] expr [,expr ...]
  [ORDER BY {unsigned_integer | col_name | expr}
    [ASC | DESC] [,col_name ...]]
  [SEPARATOR str_val])
```

```sql
mysql> SELECT student_name,
            GROUP_CONCAT(test_score)
       FROM student
       GROUP BY student_name;
```

Or:

```sql
mysql> SELECT student_name,
            GROUP_CONCAT(DISTINCT test_score
              ORDER BY test_score DESC SEPARATOR ' ')
       FROM student
       GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (,) To specify a separator
explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet`. The syntax to change the value of `group_concat_max_len` at runtime is as follows, where `val` is an unsigned integer:

```sql
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

- **JSON_ARRAYAGG(** col_or_expr **) [over_clause]**

Aggregates a result set as a single JSON array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns `NULL` if the result contains no rows, or in the event of an error.

As of MySQL 8.0.14, this function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

```sql
mysql> SELECT o_id, attribute, value FROM t3;
```

<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

```sql
mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes FROM t3 GROUP BY o_id;
```

<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>[&quot;color&quot;, &quot;fabric&quot;]</td>
</tr>
<tr>
<td>3</td>
<td>[&quot;color&quot;, &quot;shape&quot;]</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

- **JSON_OBJECTAGG(key, value) [over_clause]**

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns `NULL` if the result contains no rows, or in the event of an error. An error occurs if any key name is `NULL` or the number of arguments is not equal to 2.

As of MySQL 8.0.14, this function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

```sql
mysql> SELECT o_id, attribute, value FROM t3;
```

<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)
Duplicate key handling

When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL JSON data type specification that does not permit duplicate keys, only the last value encountered is used with that key in the returned object ("last duplicate key wins"). This means that the result of using this function on columns from a `SELECT` can depend on the order in which the rows are returned, which is not guaranteed. When used as a window function, if there are duplicate keys within a frame, only the last value for the key is present in the result. The value for the key from last row in the frame is deterministic if the `ORDER BY` specification guarantees that the values have a specific order. If not, the resulting value of the key is nondeterministic. Consider the following:

```sql
CREATE TABLE t(c VARCHAR(10), i INT);
INSERT INTO t VALUES
('key', 3), ('key', 4), ('key', 5);
SELECT c, i FROM t;
SELECT JSON_OBJECTAGG(c, i) FROM t;
DELETE FROM t;
```
Aggregate (GROUP BY) Function Descriptions

('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
mysql> SELECT c, i FROM t;
+------+------+
| c
| i
|
+------+------+
| key |
3 |
| key |
5 |
| key |
4 |
+------+------+
3 rows in set (0.00 sec)
mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 4}
|
+----------------------+
1 row in set (0.00 sec)

The key chosen from the last query is nondeterministic. If you prefer a particular key ordering, you can
invoke JSON_OBJECTAGG() as a window function by including an OVER clause with an ORDER BY
specification to impose a particular order on frame rows. The following examples show what happens
with and without ORDER BY for a few different frame specifications.
Without ORDER BY, the frame is the entire partition:
mysql> SELECT JSON_OBJECTAGG(c, i)
OVER () AS json_object FROM t;
+-------------+
| json_object |
+-------------+
| {"key": 4} |
| {"key": 4} |
| {"key": 4} |
+-------------+

With ORDER BY, where the frame is the default of RANGE BETWEEN UNBOUNDED PRECEDING AND
CURRENT ROW (in both ascending and descending order):
mysql> SELECT JSON_OBJECTAGG(c, i)
OVER (ORDER BY i) AS json_object FROM t;
+-------------+
| json_object |
+-------------+
| {"key": 3} |
| {"key": 4} |
| {"key": 5} |
+-------------+
mysql> SELECT JSON_OBJECTAGG(c, i)
OVER (ORDER BY i DESC) AS json_object FROM t;
+-------------+
| json_object |
+-------------+
| {"key": 5} |
| {"key": 4} |
| {"key": 3} |
+-------------+

With ORDER BY and an explicit frame of the entire partition:

2069


Aggregate (GROUP BY) Function Descriptions

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    OVER (ORDER BY i
    ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING)
    AS json_object
FROM t;
+-------------+
| json_object |
|------------+|
| (*key*: 5)  |
| (*key*: 5)  |
| (*key*: 5)  |
+-------------+
```

To return a particular key value (such as the smallest or largest), include a `LIMIT` clause in the appropriate query. For example:

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    OVER (ORDER BY i) AS json_object FROM t LIMIT 1;
+-------------+
| json_object |
|------------+|
| (*key*: 3)  |
+-------------+
```

To return a particular key value (such as the smallest or largest), include a `LIMIT` clause in the appropriate query. For example:

```sql
mysql> SELECT JSON_OBJECTAGG(c, i)
    OVER (ORDER BY i DESC) AS json_object FROM t LIMIT 1;
+-------------+
| json_object |
|------------+|
| (*key*: 5)  |
+-------------+
```

See Normalization, Merging, and Autowrapping of JSON Values, for additional information and examples.

- **MAX([DISTINCT] expr) [over_clause]**

  Returns the maximum value of `expr`. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The `DISTINCT` keyword can be used to find the maximum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

  If there are no matching rows, `MAX()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”; it cannot be used with `DISTINCT`.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
    FROM student
    GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string’s relative position in the set. This differs from how `ORDER BY` compares them.

- **MIN([DISTINCT] expr) [over_clause]**

  Returns the minimum value of `expr`. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The `DISTINCT` keyword can
be used to find the minimum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MIN()` returns `NULL`.

This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”; it cannot be used with `DISTINCT`.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string’s relative position in the set. This differs from how `ORDER BY` compares them.

- `STD(expr) [over_clause]`

  Returns the population standard deviation of `expr`. `STD()` is a synonym for the standard SQL function `STDDEV_POP()`, provided as a MySQL extension.

  If there are no matching rows, `STD()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- `STDDEV(expr) [over_clause]`

  Returns the population standard deviation of `expr`. `STDDEV()` is a synonym for the standard SQL function `STDDEV_POP()`, provided for compatibility with Oracle.

  If there are no matching rows, `STDDEV()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- `STDDEV_POP(expr) [over_clause]`

  Returns the population standard deviation of `expr` (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

  If there are no matching rows, `STDDEV_POP()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- `STDDEV_SAMP(expr) [over_clause]`

  Returns the sample standard deviation of `expr` (the square root of `VAR_SAMP()`).

  If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

  This function executes as a window function if `over_clause` is present. `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- `SUM([DISTINCT] expr) [over_clause]`

  Returns the sum of `expr`. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of `expr`.
GROUP BY Modifiers

If there are no matching rows, SUM() returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”; it cannot be used with DISTINCT.

- \texttt{VAR\_POP(expr) [over\_clause]}

Returns the population standard variance of expr. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use \texttt{VARIANCE()}, which is equivalent but is not standard SQL.

If there are no matching rows, \texttt{VAR\_POP()} returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- \texttt{VAR\_SAMP(expr) [over\_clause]}

Returns the sample variance of expr. That is, the denominator is the number of rows minus one.

If there are no matching rows, \texttt{VAR\_SAMP()} returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

- \texttt{VARIANCE(expr) [over\_clause]}

Returns the population standard variance of expr. \texttt{VARIANCE()} is a synonym for the standard SQL function \texttt{VAR\_POP()}, provided as a MySQL extension.

If there are no matching rows, \texttt{VARIANCE()} returns NULL.

This function executes as a window function if over_clause is present. over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

12.20.2 GROUP BY Modifiers

The \texttt{GROUP BY} clause permits a WITH ROLLUP modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. ROLLUP thus enables you to answer questions at multiple levels of analysis with a single query. For example, ROLLUP can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a \texttt{sales} table has \texttt{year}, \texttt{country}, \texttt{product}, and \texttt{profit} columns for recording sales profitability:

```sql
CREATE TABLE sales
(
    year INT,
    country VARCHAR(20),
    product VARCHAR(32),
    profit INT
);
```

To summarize table contents per year, use a simple \texttt{GROUP BY} like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
```
GROUP BY Modifiers

FROM sales
GROUP BY year;

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use ROLLUP, which provides both levels of analysis with a single query. Adding a WITH ROLLUP modifier to the GROUP BY clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

The NULL value in the year column identifies the grand total super-aggregate line.

ROLLUP has a more complex effect when there are multiple GROUP BY columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without ROLLUP, a summary of the sales table based on year, country, and product might look like this, where the output indicates summary values only at the year/country/product level of analysis:

mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product;

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>

With ROLLUP added, the query produces several extra rows:

mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP;

With ROLLUP added, the query produces several extra rows:
Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the `product` column set to `NULL`.

- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.

- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column position, the server identifies which columns to set to `NULL` by position.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as `NULL` values only in the select list or `HAVING` clause. You cannot test them as `NULL` values in join conditions or the `WHERE` clause to determine which rows to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value. To test the distinction, use the `GROUPING()` function, described later.

Previously, MySQL did not allow the use of `DISTINCT` or `ORDER BY` in a query having a `WITH ROLLUP` option. This restriction is lifted in MySQL 8.0.12 and later. (Bug #87450, Bug #86311, Bug #26640100, Bug #26073513)

For `GROUP BY ... WITH ROLLUP` queries, to test whether `NULL` values in the result represent super-aggregate values, the `GROUPING()` function is available for use in the select list, `HAVING` clause, and (as of MySQL 8.0.12) `ORDER BY` clause. For example, `GROUPING(year)` returns 1 when `NULL` in the
year column occurs in a super-aggregate row, and 0 otherwise. Similarly, GROUPING(country) and GROUPING(product) return 1 for super-aggregate NULL values in the country and product columns, respectively:

```sql
mysql> SELECT
    year, country, product, SUM(profit) AS profit,
    GROUPING(year) AS grp_year,
    GROUPING(country) AS grp_country,
    GROUPING(product) AS grp_product
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

<table>

Instead of displaying the GROUPING() results directly, you can use GROUPING() to substitute labels for super-aggregate NULL values:

```sql
mysql> SELECT
    IF(GROUPING(year), 'All years', year) AS year,
    IF(GROUPING(country), 'All countries', country) AS country,
    IF(GROUPING(product), 'All products', product) AS product,
    SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

<table>
<thead>
<tr>

</tbody>
</table>
With multiple expression arguments, `GROUPING()` returns a result representing a bitmask that combines the results for each expression, with the lowest-order bit corresponding to the result for the rightmost expression. For example, `GROUPING(year, country, product)` is evaluated like this:

```
result for GROUPING(product)
+ result for GROUPING(country) << 1
+ result for GROUPING(year) << 2
```

The result of such a `GROUPING()` is nonzero if any of the expressions represents a super-aggregate `NULL`, so you can return only the super-aggregate rows and filter out the regular grouped rows like this:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    -> FROM sales
    -> GROUP BY year, country, product WITH ROLLUP
    -> HAVING GROUPING(year, country, product) <> 0;
```

The `sales` table contains no `NULL` values, so all `NULL` values in a `ROLLUP` result represent super-aggregate values. When the data set contains `NULL` values, `ROLLUP` summaries may contain `NULL` values not only in super-aggregate rows, but also in regular grouped rows. `GROUPING()` enables these to be distinguished. Suppose that table `t1` contains a simple data set with two grouping factors for a set of `quantity` values, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
```

```
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | small |       10 |
| ball | large |       20 |
| ball | NULL  |        5 |
| hoop | small |       15 |
| hoop | large |        5 |
| hoop | NULL  |        3 |
+------+-------+----------+
```

A simple `ROLLUP` operation produces these results, in which it is not so easy to distinguish `NULL` values in super-aggregate rows from `NULL` values in regular grouped rows:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
    -> FROM t1
    -> GROUP BY name, size WITH ROLLUP;
```

```
+-------+-------+------+
| name  | size  | quantity |
+-------+-------+------+
| ball  | NULL  |      5 |
| ball  | large |     20 |
+-------+-------+------+
```
GROUP BY Modifiers

| ball | small | 10 |
| ball | NULL | 35 |
| hoop | NULL | 3 |
| hoop | large | 5 |
| hoop | small | 15 |
| hoop | NULL | 23 |
| NULL | NULL | 58 |

Using `GROUPING()` to substitute labels for the super-aggregate `NULL` values makes the result easier to interpret:

```sql
mysql> SELECT IF(GROUPING(name) = 1, 'All items', name) AS name,
          IF(GROUPING(size) = 1, 'All sizes', size) AS size,
          SUM(quantity) AS quantity
      FROM t1
      GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>All sizes</td>
<td>23</td>
</tr>
<tr>
<td>All items</td>
<td>All sizes</td>
<td>58</td>
</tr>
</tbody>
</table>

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of `ROLLUP`.

Prior to MySQL 8.0.12, when you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` were mutually exclusive in MySQL. However, you still have some control over sort order. To work around the restriction that prevents using `ROLLUP` with `ORDER BY` and achieve a specific sort order of grouped results, generate the grouped result set as a derived table and apply `ORDER BY` to it. For example:

```sql
mysql> SELECT * FROM
      (SELECT year, SUM(profit) AS profit
          FROM sales
          GROUP BY year WITH ROLLUP)
      AS dt
      ORDER BY year DESC;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

As of MySQL 8.0.12, `ORDER BY` and `ROLLUP` can be used together, which enables the use of `ORDER BY` and `GROUPING()` to achieve a specific sort order of grouped results. For example:

```sql
mysql> SELECT year, SUM(profit) AS profit
      FROM sales
      GROUP BY year WITH ROLLUP
      ORDER BY GROUPING(year) DESC;
```
In both cases, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the end for ascending sort, at the beginning for descending sort).

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
       FROM sales
       GROUP BY year, country, product WITH ROLLUP
       LIMIT 5;
+------+---------+------------+--------+
| year | country | product    | profit |
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2000 | Finland | NULL       |   1600 |
| 2000 | India   | Calculator |   150 |
| 2000 | India   | Computer   |   1200 |
+------+---------+------------+--------+
```

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the select list. (For information about nonaggregated columns and `GROUP BY`, see Section 12.20.3, "MySQL Handling of GROUP BY"). In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
       FROM sales
       GROUP BY year WITH ROLLUP;
+------+---------+--------+
| year | country | profit |
| 2000 | India   |   4525 |
| 2001 | USA     |   3010 |
| NULL | USA     |   7535 |
+------+---------+--------+
```

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. With `ONLY_FULL_GROUP_BY` enabled, you can still execute the query by using the `ANY_VALUE()` function for nondeterministic-value columns:

```
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
       FROM sales
       GROUP BY year WITH ROLLUP;
+------+---------+--------+
| year | country | profit |
| 2000 | India   |   4525 |
+------+---------+--------+
```
12.20.3 MySQL Handling of GROUP BY

SQL-92 and earlier does not permit queries for which the select list, HAVING condition, or ORDER BY list refer to nonaggregated columns that are not named in the GROUP BY clause. For example, this query is illegal in standard SQL-92 because the nonaggregated name column in the select list does not appear in the GROUP BY:

```sql
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL-92, the name column must be omitted from the select list or named in the GROUP BY clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on GROUP BY columns: If such a relationship exists between name and custid, the query is legal. This would be the case, for example, were custid a primary key of customers.

MySQL implements detection of functional dependence. If the ONLY_FULL_GROUP_BY SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, HAVING condition, or ORDER BY list refer to nonaggregated columns that are neither named in the GROUP BY clause nor are functionally dependent on them.

If ONLY_FULL_GROUP_BY is disabled, a MySQL extension to the standard SQL use of GROUP BY permits the select list, HAVING condition, or ORDER BY list to refer to nonaggregated columns even if the columns are not functionally dependent on GROUP BY columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an ORDER BY clause. Result set sorting occurs after values have been chosen, and ORDER BY does not affect which value within each group the server chooses. Disabling ONLY_FULL_GROUP_BY is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the GROUP BY are the same for each group.

You can achieve the same effect without disabling ONLY_FULL_GROUP_BY by using ANY_VALUE() to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with ONLY_FULL_GROUP_BY enabled because the nonaggregated address column in the select list is not named in the GROUP BY clause:

```sql
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if name is a primary key of t or is a unique NOT NULL column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if name is a primary key, its value determines the value of address because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of address value in a group and no need to reject the query.
The query is invalid if name is not a primary key of t or a unique NOT NULL column. In this case, no functional dependency can be inferred and an error occurs:

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

If you know that, for a given data set, each name value in fact uniquely determines the address value, address is effectively functionally dependent on name. To tell MySQL to accept the query, you can use the ANY_VALUE() function:

```sql
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable ONLY_FULL_GROUP_BY.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 12.20.4, “Detection of Functional Dependence”.

If a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list, HAVING condition, or ORDER BY list with ONLY_FULL_GROUP_BY enabled:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without GROUP BY, there is a single group and it is nondeterministic which name value to choose for the group. Here, too, ANY_VALUE() can be used, if it is immaterial which name value MySQL chooses:

```sql
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

ONLY_FULL_GROUP_BY also affects handling of queries that use DISTINCT and ORDER BY. Consider the case of a table t with three columns c1, c2, and c3 that contains these rows:

```
c1 c2 c3
1 2 A
3 4 B
1 2 C
```

Suppose that we execute the following query, expecting the results to be ordered by c3:

```sql
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of c3, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has DISTINCT and ORDER BY is rejected as invalid if any ORDER BY expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
• All columns referenced by the expression and belonging to the query’s selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```sql
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```sql
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because `FLOOR(value/100)` is a noncolumn expression:

```sql
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```sql
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

The alias `val` is considered a column expression in the `GROUP BY` clause.

In the presence of a noncolumn expression in the `GROUP BY` clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with `ONLY_FULL_GROUP_BY` SQL mode enabled, the query containing `GROUP BY id, FLOOR(value/100)` is valid because that same `FLOOR()` expression occurs in the select list. However, MySQL does not try to recognize functional dependence on `GROUP BY` noncolumn expressions, so the following query is invalid with `ONLY_FULL_GROUP_BY` enabled, even though the third selected expression is a simple formula of the `id` column and the `FLOOR()` expression in the `GROUP BY` clause:

```sql
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```sql
SELECT id, F, id+F
FROM
  (SELECT id, FLOOR(value/100) AS F
   FROM tbl_name
   GROUP BY id, FLOOR(value/100)) AS dt;
```
12.20.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

\{X\} \rightarrow \{Y\}

Understand this as “\(X\) uniquely determines \(Y\),” which also means that \(Y\) is functionally dependent on \(X\).

The examples use the world database, which can be downloaded from https://dev.mysql.com/doc/index-other.html. You can find details on how to install the database on the same page.

- Functional Dependencies Derived from Keys
- Functional Dependencies Derived from Multiple-Column Keys and from Equalities
- Functional Dependency Special Cases
- Functional Dependencies and Views
- Combinations of Functional Dependencies

Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```sql
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
GROUP BY co.Code;
```

\(co.Code\) is a primary key of \(co\), so all columns of \(co\) are functionally dependent on it, as expressed using this notation:

\{co.Code\} \rightarrow \{co.*\}

Thus, \(co.name\) is functionally dependent on \(GROUP BY\) columns and the query is valid.

A UNIQUE index over a NOT NULL column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a UNIQUE index that permits NULL values because it permits multiple NULL values and in that case uniqueness is lost.)

Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```sql
SELECT co.Name, cl.Language,
    cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
GROUP BY cl.CountryCode, cl.Language;
```

The pair \((cl.CountryCode, cl.Language)\) is a two-column composite primary key of \(cl\), so that column pair uniquely determines all columns of \(cl\):

\{cl.CountryCode, cl.Language\} \rightarrow \{cl.*\}
Moreover, because of the equality in the `WHERE` clause:

```
{cl.CountryCode} -> {co.Code}
```

And, because `co.Code` is primary key of `co`:

```
{co.Code} -> {co.*}
```

“Uniquely determines” relationships are transitive, therefore:

```
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

As a result, the query is valid.

As with the previous example, a `UNIQUE` key over `NOT NULL` columns could be used instead of a primary key.

An `INNER JOIN` condition can be used instead of `WHERE`. The same functional dependencies apply:

```sql
SELECT co.Name, cl.Language,
       cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl INNER JOIN country co
GROUP BY cl.CountryCode, cl.Language;
```

**Functional Dependency Special Cases**

Whereas an equality test in a `WHERE` condition or `INNER JOIN` condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a `LEFT JOIN`:

```sql
SELECT co.Name, cl.Language,
       cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl LEFT JOIN country co
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is `NULL`-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

```
{cl.CountryCode}  ->  {co.Code}
```

`cl.CountryCode` is itself functionally dependent on `{cl.CountryCode, cl.Language}` which is a primary key.

If in the join result `co.Code` is `NULL`-complemented, `co.Name` is as well. If `co.Code` is not `NULL`-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

```
{co.Code}  ->  {co.Name}
```

Which yields:
Detection of Functional Dependence

\{\text{cl.CountryCode, cl.Language}\} \rightarrow \{\text{cl.*}, \text{co.*}\}

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

\begin{verbatim}
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM country co LEFT JOIN countrylanguage cl 
GROUP BY cl.CountryCode, cl.Language;
\end{verbatim}

Now this relationship does \textit{not} apply:

\{\text{cl.CountryCode, cl.Language}\} \rightarrow \{\text{cl.*}, \text{co.*}\}

Indeed, all \texttt{NULL}-complemented rows made for \texttt{cl} will be put into a single group (they have both \texttt{GROUP BY} columns equal to \texttt{NULL}), and inside this group the value of \texttt{co.Name} can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the \texttt{LEFT JOIN}. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

\section*{Functional Dependencies and Views}

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

\begin{verbatim}
CREATE VIEW Country2 AS 
SELECT co.Code, UPPER(co.Name) AS UpperName, 
COUNT(cl.Language) AS OfficialLanguages 
FROM country AS co JOIN countrylanguage AS cl 
WHERE cl.isOfficial = 'T' 
GROUP BY co.Code;
\end{verbatim}

This definition is valid because:

\{\text{co.Code}\} \rightarrow \{\text{co.*}\}

In the view result, the first selected column is \texttt{co.Code}, which is also the group column and thus determines all other selected expressions:

\{\text{Country2.Code}\} \rightarrow \{\text{Country2.*}\}

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the \texttt{city} table:

\begin{verbatim}
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages, 
COUNT(*) AS Cities 
FROM country2 AS co2 JOIN city ci 
ON cl.CountryCode = co2.Code 
GROUP BY co2.Code;
\end{verbatim}
This query is valid because, as seen previously:

{co2.Code} -> {co2.*}

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if country2 were a derived table (or common table expression), as in:

```sql
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages, COUNT(*) AS Cities
FROM
  (SELECT co.Code, UPPER(co.Name) AS UpperName, COUNT(cl.Language) AS OfficialLanguages
   FROM country AS co JOIN countrylanguage AS cl
   WHERE cl.isOfficial='T'
   GROUP BY co.Code
  ) AS co2
GROUP BY co2.Code;
```

Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

12.21 Window Functions

MySQL supports window functions that, for each row from a query, perform a calculation using rows related to that row. The following sections discuss how to use window functions, including descriptions of the `OVER` and `WINDOW` clauses. The first section provides descriptions of the nonaggregate window functions. For descriptions of the aggregate window functions, see Section 12.20.1, “Aggregate (GROUP BY) Function Descriptions”.

For information about optimization and window functions, see Section 8.2.1.19, “Window Function Optimization”.

12.21.1 Window Function Descriptions

This section describes nonaggregate window functions that, for each row from a query, perform a calculation using rows related to that row. Most aggregate functions also can be used as window functions; see Section 12.20.1, “Aggregate (GROUP BY) Function Descriptions”.

For window function usage information and examples, and definitions of terms such as the `OVER` clause, window, partition, frame, and peer, see Section 12.21.2, “Window Function Concepts and Syntax”.

Table 12.27 Window Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CUME_DIST()</code></td>
<td>Cumulative distribution value</td>
</tr>
<tr>
<td><code>DENSE_RANK()</code></td>
<td>Rank of current row within its partition, without gaps</td>
</tr>
<tr>
<td><code>FIRST_VALUE()</code></td>
<td>Value of argument from first row of window frame</td>
</tr>
<tr>
<td><code>LAG()</code></td>
<td>Value of argument from row lagging current row within partition</td>
</tr>
<tr>
<td><code>LAST_VALUE()</code></td>
<td>Value of argument from last row of window frame</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LEAD()</td>
<td>Value of argument from row leading current row within partition</td>
</tr>
<tr>
<td>NTH_VALUE()</td>
<td>Value of argument from N-th row of window frame</td>
</tr>
<tr>
<td>NTILE()</td>
<td>Bucket number of current row within its partition.</td>
</tr>
<tr>
<td>PERCENT_RANK()</td>
<td>Percentage rank value</td>
</tr>
<tr>
<td>RANK()</td>
<td>Rank of current row within its partition, with gaps</td>
</tr>
<tr>
<td>ROW_NUMBER()</td>
<td>Number of current row within its partition</td>
</tr>
</tbody>
</table>

In the following function descriptions, `over_clause` represents the `OVER` clause, described in Section 12.21.2, “Window Function Concepts and Syntax”. Some window functions permit a `null_treatment` clause that specifies how to handle `NULL` values when calculating results. This clause is optional. It is part of the SQL standard, but the MySQL implementation permits only `RESPECT NULLS` (which is also the default). This means that `NULL` values are considered when calculating results. `IGNORE NULLS` is parsed, but produces an error.

- **CUME_DIST() `over_clause`**

  Returns the cumulative distribution of a value within a group of values; that is, the percentage of partition values less than or equal to the value in the current row. This represents the number of rows preceding or peer with the current row in the window ordering of the window partition divided by the total number of rows in the window partition. Return values range from 0 to 1.

  This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers and have value $N/N = 1$, where $N$ is the partition size.

  `over_clause` is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

  The following query shows, for the set of values in the `val` column, the `CUME_DIST()` value for each row, as well as the percentage rank value returned by the similar `PERCENT_RANK()` function. For reference, the query also displays row numbers using `ROW_NUMBER()`:

  ```sql
  mysql> SELECT
  ... val, ROW_NUMBER() OVER w AS 'row_number',
  ... CUME_DIST() OVER w AS 'cume_dist',
  ... PERCENT_RANK() OVER w AS 'percent_rank'
  ... FROM numbers
  ... WINDOW w AS (ORDER BY val);
  ...
  +----+------------+--------------------+--------------+
  | val| row_number | cume_dist          | percent_rank |
  +----+------------+--------------------+--------------+
  |    1|          1 | 0.2222222222222222 |            0 |
  |    1|          2 | 0.2222222222222222 |            0 |
  |    2|          3 | 0.3333333333333333 | 0.25        |
  |    3|          4 | 0.6666666666666666 | 0.375       |
  |    3|          5 | 0.6666666666666666 | 0.375       |
  |    3|          6 | 0.6666666666666666 | 0.375       |
  |    4|          7 | 0.8888888888888888 | 0.75        |
  |    4|          8 | 0.8888888888888888 | 0.75        |
  |    5|          9 |                  1 |            1 |
  +----+------------+--------------------+--------------+
  ...
  ```

- **DENSE_RANK() `over_clause`**

  Returns the rank of the current row within its partition, without gaps. Peers are considered ties and receive the same rank. This function assigns consecutive ranks to peer groups; the result is that groups
Window Function Descriptions

of size greater than one do not produce noncontiguous rank numbers. For an example, see the RANK() function description.

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers.

over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

• FIRST_VALUE(expr) [null_treatment] over_clause

Returns the value of expr from the first row of the window frame.

over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”. null_treatment is as described in the section introduction.

The following query demonstrates FIRST_VALUE(), LAST_VALUE(), and two instances of NTH_VALUE():

```sql
mysql> SELECT
time, subject, val,
FIRST_VALUE(val) OVER w AS 'first',
LAST_VALUE(val) OVER w AS 'last',
NTH_VALUE(val, 2) OVER w AS 'second',
NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
ROWS UNBOUNDED PRECEDING);
```

<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>first</th>
<th>last</th>
<th>second</th>
<th>fourth</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>NULL</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>9</td>
<td>10</td>
<td>9</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>25</td>
<td>10</td>
<td>25</td>
<td>9</td>
<td>NULL</td>
</tr>
<tr>
<td>07:45:00</td>
<td>st113</td>
<td>20</td>
<td>10</td>
<td>20</td>
<td>9</td>
<td>20</td>
</tr>
<tr>
<td>07:00:00</td>
<td>xh458</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>07:15:00</td>
<td>xh458</td>
<td>10</td>
<td>0</td>
<td>10</td>
<td>10</td>
<td>NULL</td>
</tr>
<tr>
<td>07:30:00</td>
<td>xh458</td>
<td>0</td>
<td>0</td>
<td>5</td>
<td>10</td>
<td>NULL</td>
</tr>
<tr>
<td>07:45:00</td>
<td>xh458</td>
<td>30</td>
<td>0</td>
<td>30</td>
<td>10</td>
<td>30</td>
</tr>
<tr>
<td>08:00:00</td>
<td>xh458</td>
<td>25</td>
<td>0</td>
<td>25</td>
<td>10</td>
<td>30</td>
</tr>
</tbody>
</table>
```

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the NTH_VALUE() calls, the current frame does not always include the requested row; in such cases, the return value is NULL.

• LAG(expr [, N[, default]]) [null_treatment] over_clause

Returns the value of expr from the row that lags (precedes) the current row by N rows within its partition. If there is no such row, the return value is default. For example, if N is 3, the return value is default for the first two rows. If N or default are missing, the defaults are 1 and NULL, respectively.

N must be a literal nonnegative integer. If N is 0, expr is evaluated for the current row.

over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”. null_treatment is as described in the section introduction.

LAG() (and the similar LEAD() function) are often used to compute differences between rows. The following query shows a set of time-ordered observations and, for each one, the LAG() and LEAD() values from the adjoining rows, as well as the differences between the current and adjoining rows:
In the example, the `LAG()` and `LEAD()` calls use the default `N` and `default` values of 1 and `NULL`, respectively.

The first row shows what happens when there is no previous row for `LAG()` : The function returns the `default` value (in this case, `NULL`). The last row shows the same thing when there is no next row for `LEAD()`.

`LAG()` and `LEAD()` also serve to compute sums rather than differences. Consider this data set, which contains the first few numbers of the Fibonacci series:

```
mysql> SELECT n FROM fib ORDER BY n;
+------+
<table>
<thead>
<tr>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
+------+
```

The following query shows the `LAG()` and `LEAD()` values for the rows adjacent to the current row. It also uses those functions to add to the current row value the values from the preceding and following rows. The effect is to generate the next number in the Fibonacci series, and the next number after that:

```
mysql> SELECT n,
          LAG(n, 1, 0) OVER w AS 'lag',
          LEAD(n, 1, 0) OVER w AS 'lead',
          n + LAG(n, 1, 0) OVER w AS 'next_n',
          n + LEAD(n, 1, 0) OVER w AS 'next_next_n'
FROM fib
WINDOW w AS (ORDER BY n);
+------|--------|--------|--------|---------------|
<table>
<thead>
<tr>
<th>n</th>
<th>lag</th>
<th>lead</th>
<th>next_n</th>
<th>next_next_n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
<td>3</td>
<td>5</td>
</tr>
</tbody>
</table>
```
One way to generate the initial set of Fibonacci numbers is to use a recursive common table expression. For an example, see Fibonacci Series Generation.

- **LAST_VALUE**(expr) [null_treatment] over_clause

  Returns the value of expr from the last row of the window frame.

  over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.
  null_treatment is as described in the section introduction.

  For an example, see the FIRST_VALUE() function description.

- **LEAD**(expr [, N[, default]]) [null_treatment] over_clause

  Returns the value of expr from the row that leads (follows) the current row by N rows within its partition. If there is no such row, the return value is default. For example, if N is 3, the return value is default for the last two rows. If N or default are missing, the defaults are 1 and NULL, respectively.

  N must be a literal nonnegative integer. If N is 0, expr is evaluated for the current row.

  over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.
  null_treatment is as described in the section introduction.

  For an example, see the LAG() function description.

- **NTH_VALUE**(expr, N) [from_first_last] [null_treatment] over_clause

  Returns the value of expr from the N-th row of the window frame. If there is no such row, the return value is NULL.

  N must be a literal positive integer.

  from_first_last is part of the SQL standard, but the MySQL implementation permits only FROM FIRST (which is also the default). This means that calculations begin at the first row of the window. FROM LAST is parsed, but produces an error. To obtain the same effect as FROM LAST (begin calculations at the last row of the window), use ORDER BY to sort in reverse order.

  over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.
  null_treatment is as described in the section introduction.

  For an example, see the FIRST_VALUE() function description.

- **NTILE**(N) over_clause

  Divides a partition into N groups (buckets), assigns each row in the partition its bucket number, and returns the bucket number of the current row within its partition. For example, if N is 4, NTILE() divides rows into four buckets. If N is 100, NTILE() divides rows into 100 buckets.

  N must be a literal positive integer. Bucket number return values range from 1 to N.

  This function should be used with ORDER BY to sort partition rows into the desired order.

  over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”. 

  | 3 | 2 | 5 | 5 | 8 |
  | 5 | 3 | 8 | 8 | 13 |
  | 8 | 5 | 0 | 13 | 8 |
The following query shows, for the set of values in the val column, the percentile values resulting from dividing the rows into two or four groups. For reference, the query also displays row numbers using ROW_NUMBER():

```sql
mysql> SELECT val, ROW_NUMBER() OVER w AS 'row_number', NTILE(2) OVER w AS 'ntile2', NTILE(4) OVER w AS 'ntile4' FROM numbers WINDOW w AS (ORDER BY val);
```

<table>
<thead>
<tr>
<th>val</th>
<th>row_number</th>
<th>ntile2</th>
<th>ntile4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

- **PERCENT_RANK() over_clause**

Returns the the percentage of partition values less than the value in the current row, excluding the highest value. Return values range from 0 to 1 and represent the row relative rank, calculated as the result of this formula, where \( \text{rank} \) is the row rank and \( \text{rows} \) is the number of partition rows:

\[
\frac{\text{rank} - 1}{\text{rows} - 1}
\]

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers.

**over_clause** is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

For an example, see the CUME_DIST() function description.

- **RANK() over_clause**

Returns the rank of the current row within its partition, with gaps. Peers are considered ties and receive the same rank. This function does not assign consecutive ranks to peer groups if groups of size greater than one exist; the result is noncontiguous rank numbers.

This function should be used with ORDER BY to sort partition rows into the desired order. Without ORDER BY, all rows are peers.

**over_clause** is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

The following query shows the difference between RANK(), which produces ranks with gaps, and DENSE_RANK(), which produces ranks without gaps. The query shows rank values for each member of a set of values in the val column, which contains some duplicates. RANK() assigns peers (the duplicates) the same rank value, and the next greater value has a rank higher by the number of peers minus one. DENSE_RANK() also assigns peers the same rank value, but the next higher value has a rank one greater. For reference, the query also displays row numbers using ROW_NUMBER():
```sql
mysql> SELECT
val, ROW_NUMBER() OVER w AS 'row_number',
RANK() OVER w AS 'rank',
DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);

+------|------------+------+------------+
| val  | row_number | rank | dense_rank |
+------|------------+------+------------+
| 1    |          1 |    1 |          1 |
| 2    |          2 |    1 |          1 |
| 3    |          3 |    3 |          2 |
| 3    |          4 |    4 |          3 |
| 3    |          5 |    4 |          3 |
| 3    |          6 |    4 |          3 |
| 4    |          7 |    7 |          4 |
| 4    |          8 |    7 |          4 |
| 5    |          9 |    9 |          5 |
+------|------------+------+------------+
```

- **ROW_NUMBER() over_clause**

Returns the number of the current row within its partition. Rows numbers range from 1 to the number of partition rows.

ORDER BY affects the order in which rows are numbered. Without ORDER BY, row numbering is nondeterministic.

ROW_NUMBER() assigns peers different row numbers. To assign peers the same value, use RANK() or DENSE_RANK(). For an example, see the RANK() function description.

over_clause is as described in Section 12.21.2, “Window Function Concepts and Syntax”.

### 12.21.2 Window Function Concepts and Syntax

This section describes how to use window functions. Examples use the same sales information data set as found in the discussion of the GROUPING() function in Section 12.20.2, “GROUP BY Modifiers”:

```sql
mysql> SELECT * FROM sales ORDER BY country, year, product;

+----+---------+------------+--------+
| year | country | product    | profit |
+----+---------+------------+--------+
| 2000| Finland | Computer   |   1500 |
| 2000| Finland | Phone      |    100 |
| 2001| Finland | Phone      |     10 |
| 2000| India   | Calculator |     75 |
| 2000| India   | Calculator |     75 |
| 2000| India   | Computer   |  1200  |
| 2000| USA     | Calculator |     75 |
| 2000| USA     | Computer   |  1500  |
| 2001| USA     | Calculator |     50 |
| 2001| USA     | Computer   |  1500  |
| 2001| USA     | Computer   |  1200  |
| 2001| USA     | TV         |    150 |
| 2001| USA     | TV         |    100 |
```

2091
A window function performs an aggregate-like operation on a set of query rows. However, whereas an aggregate operation groups query rows into a single result row, a window function produces a result for each query row:

- The row for which function evaluation occurs is called the current row.
- The query rows related to the current row over which function evaluation occurs comprise the window for the current row.

For example, using the sales information table, these two queries perform aggregate operations that produce a single global sum for all rows taken as a group, and sums grouped per country:

```sql
mysql> SELECT SUM(profit) AS total_profit
    FROM sales;
+--------------+
<table>
<thead>
<tr>
<th>total_profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>7535</td>
</tr>
</tbody>
</table>
+--------------+
mysql> SELECT country, SUM(profit) AS country_profit
    FROM sales
    GROUP BY country
    ORDER BY country;
+---------+----------------+
<table>
<thead>
<tr>
<th>country</th>
<th>country_profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Finland</td>
<td>1610</td>
</tr>
<tr>
<td>India</td>
<td>1350</td>
</tr>
<tr>
<td>USA</td>
<td>4575</td>
</tr>
</tbody>
</table>
+---------+----------------+
```

By contrast, window operations do not collapse groups of query rows to a single output row. Instead, they produce a result for each row. Like the preceding queries, the following query uses `SUM()`, but this time as a window function:

```sql
mysql> SELECT
    year, country, product, profit,
    SUM(profit) OVER() AS total_profit,
    SUM(profit) OVER(PARTITION BY country) AS country_profit
    FROM sales
    ORDER BY country, year, product, profit;
+-------+---------+------------+--------+--------------+----------------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
<th>total_profit</th>
<th>country_profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
<td>7535</td>
<td>1610</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
<td>7535</td>
<td>1610</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
<td>7535</td>
<td>1610</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>75</td>
<td>7535</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>75</td>
<td>7535</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
<td>7535</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Calculator</td>
<td>50</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>1200</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>100</td>
<td>7535</td>
<td>4575</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>150</td>
<td>7535</td>
<td>4575</td>
</tr>
</tbody>
</table>
+-------+---------+------------+--------+--------------+----------------+
```

Each window operation in the query is signified by inclusion of an `OVER` clause that specifies how to partition query rows into groups for processing by the window function:
Window Function Concepts and Syntax

- The first `OVER` clause is empty, which treats the entire set of query rows as a single partition. The window function thus produces a global sum, but does so for each row.
- The second `OVER` clause partitions rows by country, producing a sum per partition (per country). The function produces this sum for each partition row.

Window functions are permitted only in the select list and `ORDER BY` clause. Query result rows are determined from the `FROM` clause, after `WHERE`, `GROUP BY`, and `HAVING` processing, and windowing execution occurs before `ORDER BY`, `LIMIT`, and `SELECT DISTINCT`.

The `OVER` clause is permitted for many aggregate functions, which therefore can be used as window or nonwindow functions, depending on whether the `OVER` clause is present or absent:

```
AVG()
BIT_AND()
BIT_OR()
BIT_XOR()
COUNT()
JSON_ARRAYAGG()
JSON_OBJECTAGG()
MAX()
MIN()
STDDEV_POP(), STDDEV(), STD()
STDDEV_SAMP()
SUM()
VAR_POP(), VARIANCE()
VAR_SAMP()
```

For details about each aggregate function, see Section 12.20.1, “Aggregate (GROUP BY) Function Descriptions”.

MySQL also supports nonaggregate functions that are used only as window functions. For these, the `OVER` clause is mandatory:

```
CUME_DIST()
DENSE_RANK()
FIRST_VALUE()
LAG()
LAST_VALUE()
LEAD()
NTH_VALUE()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()
```

For details about each nonaggregate function, see Section 12.21.1, “Window Function Descriptions”.

As an example of one of those nonaggregate window functions, this query uses `ROW_NUMBER()`, which produces the row number of each row within its partition. In this case, rows are numbered per country. By default, partition rows are unordered and row numbering is nondeterministic. To sort partition rows, include an `ORDER BY` clause within the window definition. The query uses unordered and ordered partitions (the `row_num1` and `row_num2` columns) to illustrate the difference between omitting and including `ORDER BY`:

```
mysql> SELECT
    ...:     year, country, product, profit,
    ...:     ROW_NUMBER() OVER(PARTITION BY country) AS row_num1,
    ...:     ROW_NUMBER() OVER(PARTITION BY country ORDER BY year, product) AS row_num2
    ...: FROM sales;

As mentioned previously, to use a window function (or treat an aggregate function as a window function), include an OVER clause following the function call. The OVER clause has two forms:

\[
\text{over\_clause:} \\
\{ \text{OVER (window\_spec)} \mid \text{OVER window\_name} \}
\]

Both forms define how the window function should process query rows. They differ in whether the window is defined directly in the OVER clause, or supplied by a reference to a named window defined elsewhere in the query:

- In the first case, the window specification appears directly in the OVER clause, between the parentheses.
- In the second case, window\_name is the name for a window specification defined by a WINDOW clause elsewhere in the query. For details, see Section 12.21.4, “Named Windows”.

For OVER (window\_spec) syntax, the window specification has several parts, all optional:

\[
\text{window\_spec:} \\
\{ \text{window\_name} \mid \text{partition\_clause} \mid \text{order\_clause} \mid \text{frame\_clause} \}
\]

If OVER() is empty, the window consists of all query rows and the window function computes a result using all rows. Otherwise, the clauses present within the parentheses determine which query rows are used to compute the function result and how they are partitioned and ordered:

- window\_name: The name of a window defined by a WINDOW clause elsewhere in the query. If window\_name appears by itself within the OVER clause, it completely defines the window. If partitioning, ordering, or framing clauses are also given, they modify interpretation of the named window. For details, see Section 12.21.4, “Named Windows”.

- partition\_clause: A PARTITION BY clause indicates how to divide the query rows into groups. The window function result for a given row is based on the rows of the partition that contains the row. If PARTITION BY is omitted, there is a single partition consisting of all query rows.

**Note**
Partitioning for window functions differs from table partitioning. For information about table partitioning, see Chapter 23, Partitioning.

partition\_clause has this syntax:

\[
\text{partition\_clause:} \\
\text{PARTITION BY expr [, expr] ...}
\]
Standard SQL requires `PARTITION BY` to be followed by column names only. A MySQL extension is to permit expressions, not just column names. For example, if a table contains a `TIMESTAMP` column named `ts`, standard SQL permits `PARTITION BY ts` but not `PARTITION BY HOUR(ts)`, whereas MySQL permits both.

- **order_clause**: An `ORDER BY` clause indicates how to sort rows in each partition. Partition rows that are equal according to the `ORDER BY` clause are considered peers. If `ORDER BY` is omitted, partition rows are unordered, with no processing order implied, and all partition rows are peers.

  `order_clause` has this syntax:

  `order_clause:
  ORDER BY expr [ASC|DESC] [, expr [ASC|DESC]] ...`

  Each `ORDER BY` expression optionally can be followed by `ASC` or `DESC` to indicate sort direction. The default is `ASC` if no direction is specified. `NULL` values sort first for ascending sorts, last for descending sorts.

  An `ORDER BY` in a window definition applies within individual partitions. To sort the result set as a whole, include an `ORDER BY` at the query top level.

- **frame_clause**: A frame is a subset of the current partition and the frame clause specifies how to define the subset. The frame clause has many subclauses of its own. For details, see Section 12.21.3, “Window Function Frame Specification”.

### 12.21.3 Window Function Frame Specification

The definition of a window used with a window function can include a frame clause. A frame is a subset of the current partition and the frame clause specifies how to define the subset.

Frames are determined with respect to the current row, which enables a frame to move within a partition depending on the location of the current row within its partition. Examples:

- By defining a frame to be all rows from the partition start to the current row, you can compute running totals for each row.

- By defining a frame as extending \( N \) rows on either side of the current row, you can compute rolling averages.

The following query demonstrates the use of moving frames to compute running totals within each group of time-ordered `level` values, as well as rolling averages computed from the current row and the rows that immediately precede and follow it:

```sql
mysql> SELECT
  time, subject, val,
  SUM(val) OVER (PARTITION BY subject ORDER BY time
  ROWS UNBOUNDED PRECEDING) AS running_total,
  AVG(val) OVER (PARTITION BY subject ORDER BY time
  ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS running_average
FROM observations;
```

```
+----------+---------+------+---------------+-----------------+
<table>
<thead>
<tr>
<th>time</th>
<th>subject</th>
<th>val</th>
<th>running_total</th>
<th>running_average</th>
</tr>
</thead>
<tbody>
<tr>
<td>07:00:00</td>
<td>st113</td>
<td>10</td>
<td>10</td>
<td>10.0000</td>
</tr>
<tr>
<td>07:15:00</td>
<td>st113</td>
<td>9</td>
<td>19</td>
<td>14.6667</td>
</tr>
<tr>
<td>07:30:00</td>
<td>st113</td>
<td>8</td>
<td>27</td>
<td>17.6667</td>
</tr>
</tbody>
</table>
+----------+---------+------+---------------+-----------------+
```
Window Function Frame Specification

| 07:30:00 | st113 | 25 | 44 | 18.0000 |
| 07:45:00 | st113 | 20 | 64 | 22.5000 |
| 07:00:00 | xh458 | 0  | 0  | 5.0000  |
| 07:15:00 | xh458 | 10 | 10 | 5.0000  |
| 07:30:00 | xh458 | 5  | 15 | 15.0000 |
| 07:45:00 | xh458 | 30 | 45 | 20.0000 |
| 08:00:00 | xh458 | 25 | 70 | 27.5000 |

For the running_average column, there is no frame row preceding the first one or following the last. In these cases, AVG() computes the average of the rows that are available.

Aggregate functions used as window functions operate on rows in the current row frame, as do these nonaggregate window functions:

FIRST_VALUE()   LAST_VALUE()   NTH_VALUE()

Standard SQL specifies that window functions that operate on the entire partition should have no frame clause. MySQL permits a frame clause for such functions but ignores it. These functions use the entire partition even if a frame is specified:

CUME_DIST()   DENSE_RANK()   LAG()   LEAD()   NTILE()   PERCENT_RANK()   RANK()   ROW_NUMBER()

The frame clause, if given, has this syntax:

```
frame_clause:
  frame_units frame_extent
frame_units:
  {ROWS | RANGE}
frame_extent:
  {frame_start | frame_between}
```

In the absence of a frame clause, the default frame depends on whether an ORDER BY clause is present, as described later in this section.

The frame_units value indicates the type of relationship between the current row and frame rows:

- **ROWS**: The frame is defined by beginning and ending row positions. Offsets are differences in row numbers from the current row number.
- **RANGE**: The frame is defined by rows within a value range. Offsets are differences in row values from the current row value.

The frame_extent value indicates the start and end points of the frame. You can specify just the start of the frame (in which case the current row is implicitly the end) or use BETWEEN to specify both frame endpoints:
Window Function Frame Specification

BETWEEN \textit{frame\_start} AND \textit{frame\_end}

\texttt{\texttt{frame\_start, frame\_end: \{ \}
\texttt{CURRENT \texttt{ROW}}}
\texttt{| UNBOUNDED \texttt{PRECEDING}}
\texttt{| UNBOUNDED \texttt{FOLLOWING}}
\texttt{| expr \texttt{PRECEDING}}
\texttt{| expr \texttt{FOLLOWING}}
\texttt{\}}

With \texttt{BETWEEN} syntax, \textit{frame\_start} must not occur later than \textit{frame\_end}.

The permitted \texttt{frame\_start} and \texttt{frame\_end} values have these meanings:

- \texttt{CURRENT \texttt{ROW}}: For \texttt{ROWS}, the bound is the current row. For \texttt{RANGE}, the bound is the peers of the current row.
- \texttt{UNBOUNDED \texttt{PRECEDING}}: The bound is the first partition row.
- \texttt{UNBOUNDED \texttt{FOLLOWING}}: The bound is the last partition row.
- \texttt{expr \texttt{PRECEDING}}: For \texttt{ROWS}, the bound is \texttt{expr} rows before the current row. For \texttt{RANGE}, the bound is the rows with values equal to the current row value minus \texttt{expr}; if the current row value is \texttt{NULL}, the bound is the peers of the row.

For \texttt{expr \texttt{PRECEDING}} (and \texttt{expr \texttt{FOLLOWING}}), \texttt{expr} can be a \? parameter marker (for use in a prepared statement), a nonnegative numeric literal, or a temporal interval of the form \texttt{INTERVAL \texttt{val unit}}. For \texttt{INTERVAL} expressions, \texttt{val} specifies nonnegative interval value, and \texttt{unit} is a keyword indicating the units in which the value should be interpreted. (For details about the permitted \texttt{units} specifiers, see the description of the \texttt{DATE\_ADD()} function in Section 12.7, “Date and Time Functions”.)

\texttt{RANGE} on a numeric or temporal \texttt{expr} requires \texttt{ORDER \texttt{BY}} on a numeric or temporal expression, respectively.

Examples of valid \texttt{expr \texttt{PRECEDING}} and \texttt{expr \texttt{FOLLOWING}} indicators:

\begin{verbatim}
10 PRECEDING
INTERVAL 5 DAY PRECEDING
5 FOLLOWING
INTERVAL '2:30' MINUTE\_SECOND FOLLOWING
\end{verbatim}

- \texttt{expr \texttt{FOLLOWING}}: For \texttt{ROWS}, the bound is \texttt{expr} rows after the current row. For \texttt{RANGE}, the bound is the rows with values equal to the current row value plus \texttt{expr}; if the current row value is \texttt{NULL}, the bound is the peers of the row.

For permitted values of \texttt{expr}, see the description of \texttt{expr \texttt{PRECEDING}}.

The following query demonstrates \texttt{FIRST\_VALUE()}, \texttt{LAST\_VALUE()}, and two instances of \texttt{NTH\_VALUE()}:

```
mysql> SELECT
    time, subject, val,
  FIRST\_VALUE(val) OVER w AS 'first',
  LAST\_VALUE(val) OVER w AS 'last',
  NTH\_VALUE(val, 2) OVER w AS 'second',
  NTH\_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
  ROWS UNBOUNDED PRECEDING);
```

</table>

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the `NTH_VALUE()` calls, the current frame does not always include the requested row; in such cases, the return value is `NULL`.

In the absence of a frame clause, the default frame depends on whether an `ORDER BY` clause is present:

- **With `ORDER BY`:** The default frame includes rows from the partition start through the current row, including all peers of the current row (rows equal to the current row according to the `ORDER BY` clause). The default is equivalent to this frame specification:

  ```
  RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
  ```

- **Without `ORDER BY`:** The default frame includes all partition rows (because, without `ORDER BY`, all partition rows are peers). The default is equivalent to this frame specification:

  ```
  RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
  ```

Because the default frame differs depending on presence or absence of `ORDER BY`, adding `ORDER BY` to a query to get deterministic results may change the results. (For example, the values produced by `SUM()` might change.) To obtain the same results but ordered per `ORDER BY`, provide an explicit frame specification to be used regardless of whether `ORDER BY` is present.

The meaning of a frame specification can be nonobvious when the current row value is `NULL`. Assuming that to be the case, these examples illustrate how various frame specifications apply:

- **`ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND 15 FOLLOWING`**

  The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- **`ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING`**

  The frame starts at `NULL` and stops at the end of the partition. Because an `ASC` sort puts `NULL` values first, the frame is the entire partition.

- **`ORDER BY X DESC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING`**

  The frame starts at `NULL` and stops at the end of the partition. Because a `DESC` sort puts `NULL` values last, the frame is only the `NULL` values.

- **`ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND UNBOUNDED FOLLOWING`**

  The frame starts at `NULL` and stops at the end of the partition. Because an `ASC` sort puts `NULL` values first, the frame is the entire partition.

- **`ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 10 FOLLOWING`**
The frame starts at NULL and stops at NULL, thus includes only rows with value NULL.

- ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 1 PRECEDING
  The frame starts at NULL and stops at NULL, thus includes only rows with value NULL.

- ORDER BY X ASC RANGE BETWEEN UNBOUNDED PRECEDING AND 10 FOLLOWING
  The frame starts at the beginning of the partition and stops at rows with value NULL. Because an ASC sort puts NULL values first, the frame is only the NULL values.

12.21.4 Named Windows

Windows can be defined and given names by which to refer to them in OVER clauses. To do this, use a WINDOW clause. If present in a query, the WINDOW clause falls between the positions of the HAVING and ORDER BY clauses, and has this syntax:

```
WINDOW window_name AS (window_spec)
  [, window_name AS (window_spec)] ...
```

For each window definition, window_name is the window name, and window_spec is the same type of window specification as given between the parentheses of an OVER clause, as described in Section 12.21.2, “Window Function Concepts and Syntax”:

```
window_spec:
  [window_name] [partition_clause] [order_clause] [frame_clause]
```

A WINDOW clause is useful for queries in which multiple OVER clauses would otherwise define the same window. Instead, you can define the window once, give it a name, and refer to the name in the OVER clauses. Consider this query, which defines the same window multiple times:

```
SELECT val,
  ROW_NUMBER() OVER (ORDER BY val) AS 'row_number',
  RANK() OVER (ORDER BY val) AS 'rank',
  DENSE_RANK() OVER (ORDER BY val) AS 'dense_rank'
FROM numbers;
```

The query can be written more simply by using WINDOW to define the window once and referring to the window by name in the OVER clauses:

```
SELECT val,
  ROW_NUMBER() OVER w AS 'row_number',
  RANK() OVER w AS 'rank',
  DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

A named window also makes it easier to experiment with the window definition to see the effect on query results. You need only modify the window definition in the WINDOW clause, rather than multiple OVER clause definitions.

If an OVER clause uses OVER (window_name ...) rather than OVER window_name, the named window can be modified by the addition of other clauses. For example, this query defines a window that includes partitioning, and uses ORDER BY in the OVER clauses to modify the window in different ways:
Window Function Restrictions

SELECT
  DISTINCT year, country,
  FIRST_VALUE(year) OVER (w ORDER BY year ASC) AS first,
  FIRST_VALUE(year) OVER (w ORDER BY year DESC) AS last
FROM sales
WINDOW w AS (PARTITION BY country);

An `OVER` clause can only add properties to a named window, not modify them. If the named window definition includes a partitioning, ordering, or framing property, the `OVER` clause that refers to the window name cannot also include the same kind of property or an error occurs:

- This construct is permitted because the window definition and the referring `OVER` clause do not contain the same kind of properties:

```
OVER (w ORDER BY country)
... WINDOW w AS (PARTITION BY country)
```

- This construct is not permitted because the `OVER` clause specifies `PARTITION BY` for a named window that already has `PARTITION BY`:

```
OVER (w PARTITION BY year)
... WINDOW w AS (PARTITION BY country)
```

The definition of a named window can itself begin with a `window_name`. In such cases, forward and backward references are permitted, but not cycles:

- This is permitted; it contains forward and backward references but no cycles:

```
WINDOW w1 AS (w2), w2 AS (), w3 AS (w1)
```

- This is not permitted because it contains a cycle:

```
WINDOW w1 AS (w2), w2 AS (w3), w3 AS (w1)
```

### 12.21.5 Window Function Restrictions

The SQL standard imposes a constraint on window functions that they cannot be used in `UPDATE` or `DELETE` statements to update rows. Using such functions in a subquery of these statements (to select rows) is permitted.

MySQL does not support these window function features:

- `DISTINCT` syntax for aggregate window functions.
- Nested window functions.
- Dynamic frame endpoints that depend on the value of the current row.

The parser recognizes these window constructs which nevertheless are not supported:

- The `GROUPS` frame units specifier is parsed, but produces an error. Only `ROWS` and `RANGE` are supported.
- The `EXCLUDE` clause for frame specification is parsed, but produces an error.
- `IGNORE NULLS` is parsed, but produces an error. Only `RESPECT NULLS` is supported.
• `FROM LAST` is parsed, but produces an error. Only `FROM FIRST` is supported.

# 12.22 Performance Schema Functions

As of MySQL 8.0.16, MySQL includes built-in SQL functions that format or retrieve Performance Schema data, and that may be used as equivalents for the corresponding `sys` schema stored functions. The built-in functions can be invoked in any schema and require no qualifier, unlike the `sys` functions, which require either a `sys` schema qualifier or that `sys` be the current schema.

## Table 12.28 Performance Schema Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>FORMAT_BYTES()</code></td>
<td>Convert byte count to value with units</td>
</tr>
<tr>
<td><code>FORMAT_PICO_TIME()</code></td>
<td>Convert time in picoseconds to value with units</td>
</tr>
<tr>
<td><code>PS_CURRENT_THREAD_ID()</code></td>
<td>Performance Schema thread ID for current thread</td>
</tr>
<tr>
<td><code>PS_THREAD_ID()</code></td>
<td>Performance Schema thread ID for given thread</td>
</tr>
</tbody>
</table>

The built-in functions supersede the corresponding `sys` functions, which are deprecated and will be removed in a future MySQL version. Applications that use the `sys` functions should be adjusted to use the built-in functions instead, keeping in mind some minor differences between the `sys` functions and the built-in functions. For details about these differences, see the function descriptions in this section.

• `FORMAT_BYTES(count)`

Given a numeric byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the number of bytes rounded to 2 decimal places and a minimum of 3 significant digits. Numbers less than 1024 bytes are represented as whole numbers and are not rounded.

The units indicator depends on the size of the byte-count argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 1023</td>
<td>bytes</td>
<td>bytes</td>
</tr>
<tr>
<td>Up to 1024² – 1</td>
<td>kibibytes</td>
<td>KiB</td>
</tr>
<tr>
<td>Up to 1024³ – 1</td>
<td>mebibytes</td>
<td>MiB</td>
</tr>
<tr>
<td>Up to 1024⁴ – 1</td>
<td>gibibytes</td>
<td>GiB</td>
</tr>
<tr>
<td>Up to 1024⁵ – 1</td>
<td>tebibytes</td>
<td>TiB</td>
</tr>
<tr>
<td>Up to 1024⁶ – 1</td>
<td>pebibytes</td>
<td>PiB</td>
</tr>
<tr>
<td>1024⁶ and up</td>
<td>exbibytes</td>
<td>EiB</td>
</tr>
</tbody>
</table>

```sql
mysql> SELECT FORMAT_BYTES(512), FORMAT_BYTES(18446644073709551615);
+-------------------+------------------------------------+
| FORMAT_BYTES(512) | FORMAT_BYTES(18446644073709551615) |
+-------------------+------------------------------------+
| 512 bytes         | 16.00 EiB                          |
+-------------------+------------------------------------+
```

`FORMAT_BYTES()` was added in MySQL 8.0.16. It may be used instead of the `sys` schema `format_bytes()` function, keeping in mind this difference:

• `FORMAT_BYTES()` uses the EiB units indicator. `sys.format_bytes()` does not.
• **FORMAT_PICO_TIME**(time_val)**

Given a numeric Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the decimal time rounded to 2 decimal places and a minimum of 3 significant digits. Times under 1 nanosecond are represented as whole numbers and are not rounded.

The units indicator depends on the size of the time-value argument as shown in the following table.

<table>
<thead>
<tr>
<th>Argument Value</th>
<th>Result Units</th>
<th>Result Units Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to 10³ – 1</td>
<td>picoseconds</td>
<td>ps</td>
</tr>
<tr>
<td>Up to 10⁶ – 1</td>
<td>nanoseconds</td>
<td>ns</td>
</tr>
<tr>
<td>Up to 10⁹ – 1</td>
<td>microseconds</td>
<td>us</td>
</tr>
<tr>
<td>Up to 10¹² – 1</td>
<td>milliseconds</td>
<td>ms</td>
</tr>
<tr>
<td>Up to 60×10¹² – 1</td>
<td>seconds</td>
<td>s</td>
</tr>
<tr>
<td>Up to 3.6×10¹⁵ – 1</td>
<td>minutes</td>
<td>min</td>
</tr>
<tr>
<td>Up to 8.64×10¹⁶ – 1</td>
<td>hours</td>
<td>h</td>
</tr>
<tr>
<td>8.64×10¹⁶ and up</td>
<td>days</td>
<td>d</td>
</tr>
</tbody>
</table>

**mysql> SELECT FORMAT_PICO_TIME(3501), FORMAT_PICO_TIME(188732396662000);**

<table>
<thead>
<tr>
<th>FORMAT_PICO_TIME(3501)</th>
<th>FORMAT_PICO_TIME(188732396662000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.50 ns</td>
<td>3.15 min</td>
</tr>
</tbody>
</table>

**FORMAT_PICO_TIME()** was added in MySQL 8.0.16. It may be used instead of the **sys** schema **format_time()** function, keeping in mind these differences:

- To indicate minutes, **sys.format_time()** uses the **m** units indicator, whereas **FORMAT_PICO_TIME()** uses **min**.
- **sys.format_time()** uses the **w** (weeks) units indicator. **FORMAT_PICO_TIME()** does not.

**PS_CURRENT_THREAD_ID()**

Returns a **BIGINT UNSIGNED** value representing the Performance Schema thread ID assigned to the current connection.

The thread ID return value is a value of the type given in the **THREAD_ID** column of Performance Schema tables.

Performance Schema configuration affects **PS_CURRENT_THREAD_ID()** the same way as for **PS_THREAD_ID()**. For details, see the description of that function.

**mysql> SELECT PS_CURRENT_THREAD_ID();**

<table>
<thead>
<tr>
<th>PS_CURRENT_THREAD_ID()</th>
</tr>
</thead>
<tbody>
<tr>
<td>52</td>
</tr>
</tbody>
</table>

**mysql> SELECT PS_THREAD_ID(CONNECTION_ID());**

<table>
<thead>
<tr>
<th>PS_THREAD_ID(CONNECTION_ID())</th>
</tr>
</thead>
</table>
PS_CURRENT_THREAD_ID() was added in MySQL 8.0.16. It may be used as a shortcut for invoking the sys schema ps_thread_id() function with an argument of NULL or CONNECTION_ID().

- **PS_THREAD_ID(connection_id)**

  Given a connection ID, returns a BIGINT UNSIGNED value representing the Performance Schema thread ID assigned to the connection ID, or NULL if no thread ID exists for the connection ID. The latter can occur for threads that are not instrumented.

  The connection ID argument is a value of the type given in the PROCESSLIST_ID column of the Performance Schema threads table or the Id column of SHOW PROCESSLIST output.

  The thread ID return value is a value of the type given in the THREAD_ID column of Performance Schema tables.

  Performance Schema configuration affects PS_THREAD_ID() operation as follows. (These remarks also apply to PS_CURRENT_THREAD_ID().)

  - Disabling the thread_instrumentation consumer disables statistics from being collected and aggregated at the thread level, but has no effect on PS_THREAD_ID().

  - If performance_schema_max_thread_instances is not 0, the Performance Schema allocates memory for thread statistics and assigns an internal ID to each thread for which instance memory is available. If there are threads for which instance memory is not available, PS_THREAD_ID() returns NULL; in this case, Performance_schema_thread_instances_lost will be nonzero.

  - If performance_schema_max_thread_instances is 0, the Performance Schema allocates no thread memory and PS_THREAD_ID() returns NULL.

  - If the Performance Schema itself is disabled, PS_THREAD_ID() produces an error.

```sql
mysql> SELECT PS_THREAD_ID(6);
+-----------------+
| PS_THREAD_ID(6) |
+-----------------+
| 45              |
+-----------------+
```

PS_THREAD_ID() was added in MySQL 8.0.16. It may be used instead of the sys schema ps_thread_id() function, keeping in mind this difference:

- With an argument of NULL, sys.ps_thread_id() returns the thread ID for the current connection, whereas PS_THREAD_ID() returns NULL. To obtain the current connection thread ID, use PS_CURRENT_THREAD_ID() instead.

### 12.23 Internal Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAN_ACCESS_COLUMN()</td>
<td>Internal use only</td>
</tr>
<tr>
<td>CAN_ACCESS_DATABASE()</td>
<td>Internal use only</td>
</tr>
</tbody>
</table>
## Internal Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAN_ACCESS_TABLE()</td>
<td>Internal use only</td>

<td>Return an integer-valued universal identifier</td>
</tr>
<tr>
<td>UUID_TO_BIN()</td>
<td>Convert string UUID to binary</td>
</tr>
<tr>
<td>VALUES()</td>
<td>Define the values to be used during an INSERT</td>
</tr>
</tbody>
</table>

• ANY_VALUE(arg)
This function is useful for GROUP BY queries when the ONLY_FULL_GROUP_BY SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the ONLY_FULL_GROUP_BY SQL mode.

For example, if `name` is a nonindexed column, the following query fails with ONLY_FULL_GROUP_BY enabled:

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among GROUP BY columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique NOT NULL column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if NULL must be permitted as a valid `name` value.)

- Use `ANY_VALUE()` to refer to `address`:

```sql
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable ONLY_FULL_GROUP_BY. This is equivalent to using `ANY_VALUE()` with ONLY_FULL_GROUP_BY enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with ONLY_FULL_GROUP_BY enabled:

```sql
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```sql
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a GROUP BY clause:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```
Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see Section 12.20.3, “MySQL Handling of GROUP BY”.

- `BIN_TO_UUID(binary_uuid), BIN_TO_UUID(binary_uuid, swap_flag)`

`BIN_TO_UUID()` is the inverse of `UUID_TO_BIN()`. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a `VARBINARY(16)` value. The return value is a `utf8` string of five hexadecimal numbers separated by dashes. (For details about this format, see the `UUID()` function description.) If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`BIN_TO_UUID()` takes one or two arguments:

- The one-argument form takes a binary UUID value. The UUID value is assumed not to have its time-low and time-high parts swapped. The string result is in the same order as the binary argument.

- The two-argument form takes a binary UUID value and a swap-flag value:
  - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The string result is in the same order as the binary argument.
  - If `swap_flag` is 1, the UUID value is assumed to have its time-low and time-high parts swapped. These parts are swapped back to their original position in the result value.

For usage examples and information about time-part swapping, see the `UUID_TO_BIN()` function description.

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

The use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X, D)`

Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. For details, see Section 12.5, “String Functions”.

- `GROUPING(expr [, expr] ...)`

For `GROUP BY` queries that include a `WITH ROLLUP` modifier, the `ROLLUP` operation produces super-aggregate output rows where `NULL` represents the set of all values. The `GROUPING()` function enables you to distinguish `NULL` values for super-aggregate rows from `NULL` values in regular grouped rows.
GROUPING() is permitted only in the select list or HAVING clause.

Each argument to GROUPING() must be an expression that exactly matches an expression in the GROUP BY clause. The expression cannot be a positional specifier. For each expression, GROUPING() produces 1 if the expression value in the current row is a NULL representing a super-aggregate value. Otherwise, GROUPING() produces 0, indicating that the expression value is a NULL for a regular result row or is not NULL.

Suppose that table t1 contains these rows, where NULL indicates something like “other” or “unknown”:

```sql
mysql> SELECT * FROM t1;
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | small | 10       |
| ball | large | 20       |
| ball | NULL  | 5        |
| hoop | small | 15       |
| hoop | large | 5        |
| hoop | NULL  | 3        |
+------+-------+----------+
```

A summary of the table without WITH ROLLUP looks like this:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
    FROM t1
    GROUP BY name, size;
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | NULL  | 35       |
| ball | large | 20       |
| ball | small | 10       |
| hoop | NULL  | 3        |
| hoop | large | 5        |
| hoop | small | 15       |
| hoop | NULL  | 23       |
+------+-------+----------+
```

The result contains NULL values, but those do not represent super-aggregate rows because the query does not include WITH ROLLUP.

Adding WITH ROLLUP produces super-aggregate summary rows containing additional NULL values. However, without comparing this result to the previous one, it is not easy to see which NULL values occur in super-aggregate rows and which occur in regular grouped rows:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
    FROM t1
    GROUP BY name, size WITH ROLLUP;
+------+-------+----------+
| name | size  | quantity |
+------+-------+----------+
| ball | NULL  | 5        |
| ball | large | 20       |
| ball | small | 10       |
| ball | NULL  | 35       |
| hoop | NULL  | 3        |
| hoop | large | 5        |
| hoop | small | 15       |
| hoop | NULL  | 23       |
+------+-------+----------+
```
To distinguish NULL values in in super-aggregate rows from those in regular grouped rows, use GROUPING(), which returns 1 only for super-aggregate NULL values:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity,
            GROUPING(name) AS grp_name,
            GROUPING(size) AS grp_size
FROM t1
GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
<th>grp_name</th>
<th>grp_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Common uses for GROUPING():

- Substitute a label for super-aggregate NULL values:

```sql
mysql> SELECT IF(GROUPING(name) = 1, 'All items', name) AS name,
            IF(GROUPING(size) = 1, 'All sizes', size) AS size,
            SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
</tr>
<tr>
<td>ball</td>
<td>All sizes</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
</tr>
<tr>
<td>hoop</td>
<td>All sizes</td>
<td>23</td>
</tr>
<tr>
<td>All items</td>
<td>All sizes</td>
<td>58</td>
</tr>
</tbody>
</table>

- Return only super-aggregate lines by filtering out the regular grouped lines:

```sql
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP
HAVING GROUPING(name) = 1 OR GROUPING(size) = 1;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>
GROUPING() permits multiple expression arguments. In this case, the GROUPING() return value represents a bitmask combined from the results for each expression, where the lowest-order bit corresponds to the result for the rightmost expression. For example, with three expression arguments, GROUPING(expr1, expr2, expr3) is evaluated like this:

```
result for GROUPING(expr3) + result for GROUPING(expr2) << 1 + result for GROUPING(expr1) << 2
```

The following query shows how GROUPING() results for single arguments combine for a multiple-argument call to produce a bitmask value:

```
mysql> SELECT
    > name, size, SUM(quantity) AS quantity,
    > GROUPING(name) AS grp_name,
    > GROUPING(size) AS grp_size,
    > GROUPING(name, size) AS grp_all
FROM t1
GROUP BY name, size WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
<th>grp_name</th>
<th>grp_size</th>
<th>grp_all</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>large</td>
<td>20</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>small</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>large</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>small</td>
<td>15</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

With multiple expression arguments, the GROUPING() return value is nonzero if any expression represents a super-aggregate value. Multiple-argument GROUPING() syntax thus provides a simpler way to write the earlier query that returned only super-aggregate rows, by using a single multiple-argument GROUPING() call rather than multiple single-argument calls:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP
HAVING GROUPING(name, size) <> 0;
```

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ball</td>
<td>NULL</td>
<td>35</td>
</tr>
<tr>
<td>hoop</td>
<td>NULL</td>
<td>23</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>58</td>
</tr>
</tbody>
</table>

Use of GROUPING() is subject to these limitations:

- Do not use subquery GROUP BY expressions as GROUPING() arguments because matching might fail. For example, matching fails for this query:

```
mysql> SELECT GROUPING((SELECT MAX(name) FROM t1))
FROM t1
```
GROUP BY (SELECT MAX(name) FROM t1) WITH ROLLUP;

ERROR 3580 (HY000): Argument #1 of GROUPING function is not in GROUP BY

- **GROUP BY** literal expressions should not be used within a **HAVING** clause as **GROUPING()** arguments. Due to differences between when the optimizer evaluates **GROUP BY** and **HAVING**, matching may succeed but **GROUPING()** evaluation does not produce the expected result. Consider this query:

```sql
SELECT a AS f1, 'w' AS f2
FROM t
GROUP BY f1, f2 WITH ROLLUP
HAVING GROUPING(f2) = 1;
```

**GROUPING()** is evaluated earlier for the literal constant expression than for the **HAVING** clause as a whole and returns 0. To check whether a query such as this is affected, use **EXPLAIN** and look for **Impossible having** in the **Extra** column.

For more information about **WITH ROLLUP** and **GROUPING()**, see Section 12.20.2, "GROUP BY Modifiers".

- **INET_ATON(expr)**

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). **INET_ATON()** returns **NULL** if it does not understand its argument.

```sql
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

**INET_ATON()** may or may not return a non-**NULL** result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, **INET_ATON()** a should not be used for such addresses.

**Note**

To store values generated by **INET_ATON()**, use an **INT UNSIGNED** column rather than **INT**, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.2.6, “Out-of-Range and Overflow Handling”.

- **INET_NTOA(expr)**

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. **INET_NTOA()** returns **NULL** if it does not understand its argument.

```sql
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- **INET6_ATON(expr)**

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the
VARBINARY data type: VARBINARY (16) for IPv6 addresses and VARBINARY (4) for IPv4 addresses. If the argument is not a valid address, INET6_ATON() returns NULL.

The following examples use HEX() to display the INET6_ATON() result in printable form:

```sql
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE0000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> 'DA000509'
```

INET6_ATON() observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.010.1` is treated as `198.51.10.1`, not `198.51.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an INT value to an IPv6 address represented in numeric form as a VARBINARY value, use this expression:

```
INET6_ATON(INET_NTOA(expr))
```

For example:

```sql
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

- **INET6_NTOA(expr)**

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, INET6_NTOA() returns NULL.

INET6_NTOA() has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```sql
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```sql
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

- The return string uses lowercase letters for IPv6 addresses.
• **IS_IPV4**(expr)

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

```sql
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if **IS_IPV4()** returns 1, **INET_ATON()** (and **INET6_ATON()**) will return non-NULL. The converse statement is not true: In some cases, **INET_ATON()** returns non-NULL when **IS_IPV4()** returns 0.

As implied by the preceding remarks, **IS_IPV4()** is more strict than **INET_ATON()** about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use **INET6_ATON()** to convert IPv4 addresses to internal form and check for a NULL result (which indicates an invalid address). **INET6_ATON()** is equally strong as **IS_IPV4()** about checking IPv4 addresses.

• **IS_IPV4_COMPAT**(expr)

This function takes an IPv6 address represented in numeric form as a binary string, as returned by **INET6_ATON()**. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form **::ipv4_address**.

```sql
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, **198.51.100.1** has this raw hexadecimal value:

```sql
mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
-> 'C6336401'
```

Expressed in IPv4-compatible form, **::198.51.100.1** is equivalent to **::c0a8:0001** or (without leading zeros) **::c0a8:1**

```sql
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')), IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')), IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

• **IS_IPV4_MAPPED**(expr)
This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```sql
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
```

```sql
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```sql
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')), IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')), IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

```sql
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

```sql
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

### IS_IPV6(expr)

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```sql
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

### IS_UUID(string_uuid)

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and `NULL` if the argument is `NULL`.

“Valid” means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeeeee
```

These other formats are also permitted:

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeeeee
{aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeeeee}
```

For the meanings of fields within the value, see the `UUID()` function description.
• **MASTER_POS_WAIT**(log_name, log_pos[, timeout][, channel])

  This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns **NULL** if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns **-1** if the timeout has been exceeded. If the slave SQL thread stops while **MASTER_POS_WAIT()** is waiting, the function returns **NULL**. If the slave is past the specified position, the function returns immediately.

  On a multithreaded slave, the function waits until expiry of the limit set by the **slave_checkpoint_group** or **slave_checkpoint_period** system variable, when the checkpoint operation is called to update the status of the slave. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

  If a **timeout** value is specified, **MASTER_POS_WAIT()** stops waiting when **timeout** seconds have elapsed. **timeout** must be greater than 0; a zero or negative **timeout** means no timeout.

  The optional **channel** value enables you to name which replication channel the function applies to. See Section 17.2.3, “Replication Channels” for more information.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when **binlog_format** is set to **STATEMENT**.

• **NAME_CONST**(name, value)

  Returns the given value. When used to produce a result set column, **NAME_CONST()** causes the column to have the given name. The arguments should be constants.
This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 24.7, “Binary Logging of Stored Programs”. You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+--------+
| myname  |
| 14      |
+--------+
1 row in set (0.00 sec)
```

See Section 13.2.10, “SELECT Syntax”, for more information about column aliases.

- **SLEEP(duration)**

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When `SLEEP()` returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-------------+
| SLEEP(1000) |
| 0           |
+-------------+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-------------+
| SLEEP(1000) |
| 1           |
+-------------+
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-------------+
| SLEEP(1000) |
| 1           |
+-------------+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
```
This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

** UUID()**

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

A UUID is designed as a number that is globally unique in space and time. Two calls to UUID() are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although UUID() values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

UUID() returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a utf8 string of five hexadecimal numbers in aaaaaaaaa-bbbb-cccc-dddd-eeeee format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

To convert between string and binary UUID values, use the UUID_TO_BIN() and BIN_TO_UUID() functions. To check whether a string is a valid UUID value, use the IS_UUID() function.
Note

UUID() does not work with statement-based replication.

- UUID_SHORT()

Returns a "short" universal identifier as a 64-bit unsigned integer. Values returned by UUID_SHORT() differ from the string-format 128-bit identifiers returned by the UUID() function and have different uniqueness properties. The value of UUID_SHORT() is guaranteed to be unique if the following conditions hold:

- The server_id value of the current server is between 0 and 255 and is unique among your set of master and slave servers
- You do not set back the system time for your server host between mysqld restarts
- You invoke UUID_SHORT() on average fewer than 16 million times per second between mysqld restarts

The UUID_SHORT() return value is constructed this way:

```
(server_id & 255) << 56  
+ (server_startup_time_in_seconds << 24)  
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```
Time-part swapping assumes the use of UUID version 1 values, such as are generated by the `UUID()` function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the `UUID()` function description.

Suppose that you have the following string UUID value:

```sql
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use `UUID_TO_BIN()`:

```sql
mysql> SELECT HEX(UUID_TO_BIN(@uuid));
+----------------------------------+
| HEX(UUID_TO_BIN(@uuid))          |
+----------------------------------+
| 6CCD780CBABA102695645B8C656024DB |
+----------------------------------+

mysql> SELECT HEX(UUID_TO_BIN(@uuid, 0));
+----------------------------------+
| HEX(UUID_TO_BIN(@uuid, 0))       |
+----------------------------------+
| 6CCD780CBABA102695645B8C656024DB |
+----------------------------------+

mysql> SELECT HEX(UUID_TO_BIN(@uuid, 1));
+----------------------------------+
| HEX(UUID_TO_BIN(@uuid, 1))       |
+----------------------------------+
| 1026BABA6CCD780C95645B8C656024DB |
+----------------------------------+
```

To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```sql
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid))      |
+--------------------------------------+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+

mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0)  |
+--------------------------------------+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+

mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1);
+--------------------------------------+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1)  |
+--------------------------------------+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+--------------------------------------+
```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID will not be recovered properly:
### 12.25 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly 1, not a value that is merely “close” to 1.

- **Well-defined rounding behavior**: For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column’s data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how...
MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.11, “Server SQL Modes”.

12.25.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, -5, -6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E-3, -1.2E3, -1.2E-3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

12.25.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is DECIMAL(M, D). The ranges of values for the arguments are as follows:

- \( M \) is the maximum number of digits (the precision). It has a range of 1 to 65.
- \( D \) is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than \( M \).

If \( D \) is omitted, the default is 0. If \( M \) is omitted, the default is 10.

The maximum value of 65 for \( M \) means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before.

Values for DECIMAL columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
For example, a DECIMAL(18, 9) column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A DECIMAL(20, 6) column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

DECIMAL columns do not store a leading + character or – character or leading 0 digits. If you insert +0003.1 into a DECIMAL(5, 1) column, it is stored as 3.1. For negative numbers, a literal – character is not stored.

DECIMAL columns do not permit values larger than the range implied by the column definition. For example, a DECIMAL(3, 0) column supports a range of −999 to 999. A DECIMAL(M, D) column permits up to M - D digits to the left of the decimal point.

The SQL standard requires that the precision of NUMERIC(M, D) be exactly M digits. For DECIMAL(M, D), the standard requires a precision of at least M digits but permits more. In MySQL, DECIMAL(M, D) and NUMERIC(M, D) are the same, and both have a precision of exactly M digits.

For a full explanation of the internal format of DECIMAL values, see the file strings/decimal.c in a MySQL source distribution. The format is explained (with an example) in the decimal2bin() function.

12.25.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for INSERT into a column with an exact data type (DECIMAL or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for INSERT is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.

- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using DECIMAL exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, 1.0/3.0 can be approximated in decimal notation as .333..., but not written as an exact number, so (1.0/3.0) * 3.0 does not evaluate to exactly 1.0.

- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as BIGINT (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the sql_mode system variable. (See Section 5.1.11, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the STRICT_ALL_TABLES or STRICT_TRANS_TABLES mode values) and
**ERROR_FOR_DIVISION_BY_ZERO.** To turn on all restrictions, you can simply use TRADITIONAL mode, which includes both strict mode values and ERROR_FOR_DIVISION_BY_ZERO:

```
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 12.25.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

<table>
<thead>
<tr>
<th>sql_mode</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>'' (Default)</td>
<td>No warning, no error; ( i ) is set to <code>NULL</code>.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; ( i ) is set to <code>NULL</code>.</td>
</tr>
<tr>
<td><code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Warning, no error; ( i ) is set to <code>NULL</code>.</td>
</tr>
</tbody>
</table>
### 12.25.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
+------------+--------------+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```sql
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
|-------+------|----------------------------------------|
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-------+------+----------------------------------------+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
+------+
| d    |
+------+
| 3    |
| 3    |
+------+
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see Section 12.25.3, “Expression Handling”).
12.25.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 12.25.3, “Expression Handling”, and Section 12.25.4, “Rounding Behavior”.

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+------------------+
| (.1 + .2) = .3   |
|                  |
|                1 |
+------------------+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
+-------------------------------+
| (.1E0 + .2E0) = .3E0          |
|                               |
|                                |
|                0               |
+-------------------------------+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds \(0.0001\) to a variable \(1,000\) times.

```
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 0;
    DECLARE d DECIMAL(10,4) DEFAULT 0;
    DECLARE f FLOAT DEFAULT 0;
    WHILE i < 10000 DO
        SET d = d + .0001;
        SET f = f + .0001E0;
        SET i = i + 1;
    END WHILE;
    SELECT d, f;
END;
```

The sum for both \(d\) and \(f\) logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+--------+------------------+
| d      | f                |
|--------+------------------|
| 1.0000 | 0.99999999999991 |
+--------+------------------+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers \(X_1\) and \(X_2\) that have scale \(S_1\) and \(S_2\), the scale of the result is \(S_1 + S_2\):

```
mysql> SELECT .01 * .01;
+-------------+
| .01 * .01   |
| 0.0001      |
+-------------+
```
Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the \texttt{ROUND()} function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (\texttt{DECIMAL} and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

  \begin{verbatim}
  mysql> SELECT ROUND(2.5), ROUND(-2.5);
  +------------+-------------+
  | ROUND(2.5) | ROUND(-2.5) |
  +------------+-------------+  
  | 3          | -3          |
  +------------+-------------+
  \end{verbatim}

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

  \begin{verbatim}
  mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
  +--------------+---------------+
  | ROUND(2.5E0) | ROUND(-2.5E0) |
  +--------------+---------------+  
  | 2            | -2            |
  +--------------+---------------+
  \end{verbatim}

Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

  \begin{verbatim}
  mysql> SET sql_mode='';
  Query OK, 0 rows affected (0.00 sec)
  mysql> CREATE TABLE t (i TINYINT);
  Query OK, 0 rows affected (0.01 sec)
  mysql> INSERT INTO t SET i = 128;
  Query OK, 1 row affected, 1 warning (0.00 sec)
  mysql> SELECT i FROM t;
  +------+
  | i    |
  +------+
  | 127   |
  +------+
  1 row in set (0.00 sec)
  \end{verbatim}

However, an error occurs if strict mode is in effect:

  \begin{verbatim}
  mysql> SET sql_mode='STRICT_ALL_TABLES';
  Query OK, 0 rows affected (0.00 sec)
  mysql> CREATE TABLE t (i TINYINT);
  Query OK, 0 rows affected (0.00 sec)
  mysql> INSERT INTO t SET i = 128;
  ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1
  \end{verbatim}
**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of NULL.

In nonstrict mode, division by zero has a result of NULL:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)
mysql> SELECT i FROM t;
+------+
| i    |
+------+
| NULL |
+------+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```sql
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0
mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6.** Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as `DECIMAL`:

```sql
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0
mysql> DESCRIBE t;
+-------+-----------------------+------+-----+---------+-------+
| Field | Type                  | Null | Key | Default | Extra |
|-------+-----------------------+------+-----+---------+-------+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double                | NO   |     | 0       |       |
+-------+-----------------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:
The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

This chapter describes the syntax for the SQL statements supported by MySQL.

## 13.1 Data Definition Statements

### 13.1.1 Atomic Data Definition Statement Support

MySQL 8.0 supports atomic Data Definition Language (DDL) statements. This feature is referred to as atomic DDL. An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. The transaction is either committed, with applicable changes persisted to the data dictionary, storage engine, and binary log, or is rolled back, even if the server halts during the operation.
Atomic DDL is made possible by the introduction of the MySQL data dictionary in MySQL 8.0. In earlier MySQL versions, metadata was stored in metadata files, nontransactional tables, and storage engine-specific dictionaries, which necessitated intermediate commits. Centralized, transactional metadata storage provided by the MySQL data dictionary removed this barrier, making it possible to restructure DDL statement operations into atomic transactions.

The atomic DDL feature is described under the following topics in this section:

- Supported DDL Statements
- Atomic DDL Characteristics
- Changes in DDL Statement Behavior
- Storage Engine Support
- Viewing DDL Logs

**Supported DDL Statements**

The atomic DDL feature supports both table and non-table DDL statements. Table-related DDL operations require storage engine support, whereas non-table DDL operations do not. Currently, only the InnoDB storage engine supports atomic DDL.

- Supported table DDL statements include `CREATE`, `ALTER`, and `DROP` statements for databases, tablespaces, tables, and indexes, and the `TRUNCATE TABLE` statement.

- Supported non-table DDL statements include:
  - `CREATE` and `DROP` statements, and, if applicable, `ALTER` statements for stored programs, triggers, views, and user-defined functions (UDFs).
  - Account management statements: `CREATE`, `ALTER`, `DROP`, and, if applicable, `RENAME` statements for users and roles, as well as `GRANT` and `REVOKE` statements.

The following statements are not supported by the atomic DDL feature:

- Table-related DDL statements that involve a storage engine other than InnoDB.
- `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- `INSTALL COMPONENT` and `UNINSTALL COMPONENT` statements.
- `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` statements.

**Atomic DDL Characteristics**

The characteristics of atomic DDL statements include the following:

- Metadata updates, binary log writes, and storage engine operations, where applicable, are combined into a single transaction.
- There are no intermediate commits at the SQL layer during the DDL operation.
- Where applicable:
  - The state of data dictionary, routine, event, and UDF caches is consistent with the status of the DDL operation, meaning that caches are updated to reflect whether or not the DDL operation was completed successfully or rolled back.
• The storage engine methods involved in a DDL operation do not perform intermediate commits, and the storage engine registers itself as part of the DDL transaction.

• The storage engine supports redo and rollback of DDL operations, which is performed in the Post-DDL phase of the DDL operation.

• The visible behaviour of DDL operations is atomic, which changes the behavior of some DDL statements. See Changes in DDL Statement Behavior.

Note

DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a COMMIT before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as START TRANSACTION ..., COMMIT, or combined with other statements within the same transaction.

Changes in DDL Statement Behavior

This section describes changes in DDL statement behavior due to the introduction of atomic DDL support.

• DROP TABLE operations are fully atomic if all named tables use an atomic DDL-supported storage engine. The statement either drops all tables successfully or is rolled back.

DROP TABLE fails with an error if a named table does not exist, and no changes are made, regardless of the storage engine. This change in behavior is demonstrated in the following example, where the DROP TABLE statement fails because a named table does not exist:

```
mysql> CREATE TABLE t1 (c1 INT);
mysql> DROP TABLE t1, t2;
ERROR 1051 (42S02): Unknown table 'test.t2'
mysql> SHOW TABLES;
+-------------+
| Tables_in_test |
+-------------+
| t1           |
+-------------+
```

Prior to the introduction of atomic DDL, DROP TABLE reports an error for the named table that does not exist but succeeds for the named table that does exist:

```
mysql> CREATE TABLE t1 (c1 INT);
mysql> DROP TABLE t1, t2;
ERROR 1051 (42S02): Unknown table 'test.t2'
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

Note

Due to this change in behavior, a partially completed DROP TABLE statement on a MySQL 5.7 master fails when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use IF EXISTS syntax in DROP TABLE statements to prevent errors from occurring for tables that do not exist.

• DROP DATABASE is atomic if all tables use an atomic DDL-supported storage engine. The statement either drops all objects successfully or is rolled back. However, removal of the database directory from
the file system occurs last and is not part of the atomic transaction. If removal of the database directory fails due to a file system error or server halt, the DROP DATABASE transaction is not rolled back.

- For tables that do not use an atomic DDL-supported storage engine, table deletion occurs outside of the atomic DROP TABLE or DROP DATABASE transaction. Such table deletions are written to the binary log individually, which limits the discrepancy between the storage engine, data dictionary, and binary log to one table at most in the case of an interrupted DROP TABLE or DROP DATABASE operation. For operations that drop multiple tables, the tables that do not use an atomic DDL-supported storage engine are dropped before tables that do.

- CREATE TABLE, ALTER TABLE, RENAME TABLE, TRUNCATE TABLE, CREATE TABLESPACE, and DROP TABLESPACE operations for tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. In earlier MySQL releases, interruption of these operations could cause discrepancies between the storage engine, data dictionary, and binary log, or leave behind orphan files. RENAME TABLE operations are only atomic if all named tables use an atomic DDL-supported storage engine.

- DROP VIEW fails if a named view does not exist, and no changes are made. The change in behavior is demonstrated in this example, where the DROP VIEW statement fails because a named view does not exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
+----------------+------------+
<table>
<thead>
<tr>
<th>Tables_in_test</th>
<th>Table_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>viewA</td>
<td>VIEW</td>
</tr>
</tbody>
</table>
+----------------+------------+
```

Prior to the introduction of atomic DDL, DROP VIEW returns an error for the named view that does not exist but succeeds for the named view that does exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
Empty set (0.00 sec)
```

Note

Due to this change in behavior, a partially completed DROP VIEW operation on a MySQL 5.7 master fails when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use IF EXISTS syntax in DROP VIEW statements to prevent an error from occurring for views that do not exist.

- Partial execution of account management statements is no longer permitted. Account management statements either succeed for all named users or roll back and have no effect if an error occurs. In earlier MySQL versions, account management statements that name multiple users could succeed for some users and fail for others.

The change in behavior is demonstrated in this example, where the second CREATE USER statement returns an error but fails because it cannot succeed for all named users.

```
mysql> CREATE USER userA;
mysql> CREATE USER userA, userB;
```
Prior to the introduction of atomic DDL, the second `CREATE USER` statement returns an error for the named user that does not exist but succeeds for the named user that does exist:

```
mysql> CREATE USER userA;
mysql> CREATE USER userA, userB;
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@
mysql> SELECT User FROM mysql.user WHERE User LIKE 'user%';
+-------+
| User  |
+-------+
| userA |
+-------+
```

**Note**

Due to this change in behavior, partially completed account management statements on a MySQL 5.7 master fail when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use `IF EXISTS` or `IF NOT EXISTS` syntax, as appropriate, in account management statements to prevent errors related to named users.

**Storage Engine Support**

Currently, only the InnoDB storage engine supports atomic DDL. Storage engines that do not support atomic DDL are exempted from DDL atomicity. DDL operations involving exempted storage engines remain capable of introducing inconsistencies that can occur when operations are interrupted or only partially completed.

To support redo and rollback of DDL operations, InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table, which is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace.

To view DDL logs that are written to the `mysql.innodb_ddl_log` table during a DDL operation, enable the `innodb_print_ddl_logs` configuration option. For more information, see Viewing DDL Logs.

**Note**

The redo logs for changes to the `mysql.innodb_ddl_log` table are flushed to disk immediately regardless of the `innodb_flush_log_at_trx_commit` setting. Flushing the redo logs immediately avoids situations where data files are modified by DDL operations but the redo logs for changes to the `mysql.innodb_ddl_log` table resulting from those operations are not persisted to disk. Such a situation could cause errors during rollback or recovery.

The InnoDB storage engine executes DDL operations in phases. DDL operations such as `ALTER TABLE` may perform the `Prepare` and `Perform` phases multiple times prior to the `Commit` phase.

1. **Prepare**: Create the required objects and write the DDL logs to the `mysql.innodb_ddl_log` table. The DDL logs define how to roll forward and roll back the DDL operation.
2. **Perform**: Perform the DDL operation. For example, perform a create routine for a `CREATE TABLE` operation.

3. **Commit**: Update the data dictionary and commit the data dictionary transaction.

4. **Post-DDL**: Replay and remove DDL logs from the `mysql.innodb_ddl_log` table. To ensure that rollback can be performed safely without introducing inconsistencies, file operations such as renaming or removing data files are performed in this final phase. This phase also removes dynamic metadata from the `mysql.innodb_dynamic_metadata` data dictionary table for `DROP TABLE`, `TRUNCATE TABLE`, and other DDL operations that rebuild the table.

DDL logs are replayed and removed from the `mysql.innodb_ddl_log` table during the **Post-DDL** phase, regardless of whether the transaction is committed or rolled back. DDL logs should only remain in the `mysql.innodb_ddl_log` table if the server is halted during a DDL operation. In this case, the DDL logs are replayed and removed after recovery.

In a recovery situation, a DDL transaction may be committed or rolled back when the server is restarted. If the data dictionary transaction that was performed during the **Commit** phase of a DDL operation is present in the redo log and binary log, the operation is considered successful and is rolled forward. Otherwise, the incomplete data dictionary transaction is rolled back when InnoDB replays data dictionary redo logs, and the DDL transaction is rolled back.

**Viewing DDL Logs**

To view DDL logs that are written to the `mysql.innodb_ddl_log` data dictionary table during atomic DDL operations that involve the InnoDB storage engine, enable `innodb_print_ddl_logs` to have MySQL write the DDL logs to `stderr`. Depending on the host operating system and MySQL configuration, `stderr` may be the error log, terminal, or console window. See Section 5.4.2.2, "Default Error Log Destination Configuration".

InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table to support redo and rollback of DDL operations. The `mysql.innodb_ddl_log` table is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace. Like other hidden data dictionary tables, the `mysql.innodb_ddl_log` table cannot be accessed directly in non-debug versions of MySQL. (See Section 14.1, “Data Dictionary Schema”.) The structure of the `mysql.innodb_ddl_log` table corresponds to this definition:

```sql
CREATE TABLE mysql.innodb_ddl_log (  
id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  
thread_id BIGINT UNSIGNED NOT NULL,  
type INT UNSIGNED NOT NULL,  
space_id INT UNSIGNED,  
pageno INT UNSIGNED,  
index_id BIGINT UNSIGNED,  
table_id BIGINT UNSIGNED,  
old_file_path VARCHAR(512) COLLATE UTF8_BIN,  
nfile_path VARCHAR(512) COLLATE UTF8_BIN,  
KEY(thread_id) );
```

- **id**: A unique identifier for a DDL log record.
- **thread_id**: Each DDL log record is assigned a `thread_id`, which is used to replay and remove DDL logs that belong to a particular DDL transaction. DDL transactions that involve multiple data file operations generate multiple DDL log records.
- **type**: The DDL operation type. Types include `FREE` (drop an index tree), `DELETE` (delete a file), `RENAME` (rename a file), or `DROP` (drop metadata from the `mysql.innodb_dynamic_metadata` data dictionary table).
ALTER DATABASE Syntax

- **space_id**: The tablespace ID.
- **page_no**: A page that contains allocation information; an index tree root page, for example.
- **index_id**: The index ID.
- **table_id**: The table ID.
- **old_file_path**: The old tablespace file path. Used by DDL operations that create or drop tablespace files; also used by DDL operations that rename a tablespace.
- **new_file_path**: The new tablespace file path. Used by DDL operations that rename tablespace files.

This example demonstrates enabling `innodb_print_ddl_logs` to view DDL logs written to `stderr` for a `CREATE TABLE` operation.

```sql
mysql> SET GLOBAL innodb_print_ddl_logs=1;
mysql> CREATE TABLE t1 (c1 INT) ENGINE = InnoDB;
```

13.1.2 ALTER DATABASE Syntax

ALTER DATABASE syntax:

```sql
ALTER DATABASE [db_name]
  alter_specification ...
```

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

National Language Characteristics

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. Chapter 10, Character Sets, Collations, Unicode, discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the `SHOW CHARACTER SET` and `SHOW COLLATION` statements. See Section 13.7.6.3, “SHOW CHARACTER SET Syntax”, and Section 13.7.6.4, “SHOW COLLATION Syntax”, for more information.
If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.)

### 13.1.3 ALTER EVENT Syntax

```sql
ALTER
[DEFINER = { user | CURRENT_USER }]
EVENT event_name
[ON SCHEDULE schedule]
[ON COMPLETION [NOT] PRESERVE]
[RENAME TO new_event_name]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'string']
[DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See Section 13.1.13, “CREATE EVENT Syntax”.)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event. The `ALTER EVENT` works only with an existing event:

```sql
mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    > EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```sql
CREATE EVENT myevent
  ON SCHEDULE
  EVERY 6 HOUR
  COMMENT 'A sample comment.'
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```sql
ALTER EVENT myevent
  ON SCHEDULE
  EVERY 12 HOUR
  STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```sql
ALTER EVENT myevent
  ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO
    DELETE FROM mytable;
```
ALTER FUNCTION Syntax

TRUNCATE TABLE myschema.mytable;

Specify the options in an ALTER EVENT statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for CREATE EVENT such as ENABLE.

To disable myevent, use this ALTER EVENT statement:

```
ALTER EVENT myevent
    DISABLE;
```

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use SELECT FROM DUAL. This is true for both ALTER EVENT and CREATE EVENT statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an ALTER EVENT statement that contains another ALTER EVENT statement in its DO clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the ALTER EVENT statement's RENAME TO clause. This statement renames the event myevent to yourevent:

```
ALTER EVENT myevent
    RENAME TO yourevent;
```

You can also move an event to a different database using ALTER EVENT ... RENAME TO ... and db_name.event_name notation, as shown here:

```
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the EVENT privilege on both the olddb and newdb databases.

Note

There is no RENAME EVENT statement.

The value DISABLE ON SLAVE is used on a replication slave instead of ENABLE or DISABLE to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, DISABLE ON SLAVE is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 17.4.1.16, “Replication of Invoked Features”, for more information.

13.1.4 ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]
```

characteristic:
  - COMMENT 'string'
  - LANGUAGE SQL
This statement can be used to change the characteristics of a stored function. More than one change may be specified in an ALTER FUNCTION statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using DROP FUNCTION and CREATE FUNCTION.

You must have the ALTER ROUTINE privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the ALTER FUNCTION statement might also require the SUPER privilege, as described in Section 24.7, “Binary Logging of Stored Programs”.

### 13.1.5 ALTER INSTANCE Syntax

```sql
ALTER INSTANCE instance_action

instance_action: {  
   ROTATE INNODB MASTER KEY  
   | RELOAD TLS [NO ROLLBACK ON ERROR]
}
```

**ALTER INSTANCE** defines actions applicable to a MySQL server instance. The statement supports these actions:

- **ALTER INSTANCE ROTATE INNODB MASTER KEY**

  This action rotates the master encryption key used for InnoDB tablespace encryption. Key rotation requires the ENCRYPTION_KEY_ADMIN or SUPER privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 6.5.4, “The MySQL Keyring”.

  **ALTER INSTANCE ROTATE INNODB MASTER KEY** supports concurrent DML. However, it cannot be run concurrently with CREATE TABLE ... ENCRYPTION or ALTER TABLE ... ENCRYPTION operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

  **ALTER INSTANCE ROTATE INNODB MASTER KEY** statements are written to the binary log so that they can be executed on replicated servers.

  For additional **ALTER INSTANCE ROTATE INNODB MASTER KEY** usage information, see Section 15.6.3.9, “Tablespace Encryption”.

- **ALTER INSTANCE RELOAD TLS**

  This action reconfigures the SSL context from the current values of the system variables that define the context. It also updates the status variables that reflect the active context values. This action requires the CONNECTION_ADMIN privilege.

  By default, the **RELOAD TLS** action rolls back with an error and has no effect if the configuration values do not permit creation of a new SSL context. The previous context values continue to be used for new connections.

  If the optional **NO ROLLBACK ON ERROR** clause is given and a new context cannot be created, rollback does not occur. Instead, a warning is generated and SSL is disabled for new connections.

  **ALTER INSTANCE RELOAD TLS** statements are not written to the binary log (and thus are not replicated). SSL configuration is local and depends on local files not necessarily present on all servers involved.
ALTER LOGFILE GROUP Syntax

For additional information about reconfiguring the SSL context, including which system and status variables are context-related, see Server-Side Runtime Configuration for Encrypted Connections.

13.1.6 ALTER LOGFILE GROUP Syntax

```
ALTER LOGFILE GROUP  logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [-] size]
    [WAIT]
    ENGINE [-] engine_name
```

This statement adds an UNDO file named 'file_name' to an existing log file group `logfile_group`. An ALTER LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. No DROP UNDOFILE clause is currently supported.

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional INITIAL_SIZE parameter sets the UNDO file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow size with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (megabytes) or G (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB). (Bug #29574)

**Note**

WAIT is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The ENGINE parameter (required) determines the storage engine which is used by this log file group, with engine_name being the name of the storage engine. Currently, the only accepted values for engine_name are "NDBCLUSTER" and "NDB". The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using CREATE LOGFILE GROUP (see Section 13.1.16, "CREATE LOGFILE GROUP Syntax"):

```
ALTER LOGFILE GROUP lg_3
    ADD UNDOFILE 'undo_10.dat'
    INITIAL_SIZE=32M
    ENGINE=NDBCLUSTER;
```

When ALTER LOGFILE GROUP is used with ENGINE = NDBCLUSTER (alternatively, ENGINE = NDB), an UNDO log file is created on each NDB Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:
ALTER PROCEDURE Syntax

mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
+-------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+-------------+----------------------+----------------+
4 rows in set (0.01 sec)

(See Section 25.11, “The INFORMATION_SCHEMA FILES Table”.)

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

ALTER LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. For more information, see Section 22.5.13, “NDB Cluster Disk Data Tables”.

13.1.7 ALTER PROCEDURE Syntax

ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  COMMENT 'string'
  LANGUAGE SQL
  { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  SQL SECURITY { DEFINER | INVOKER }

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an ALTER PROCEDURE statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using DROP PROCEDURE and CREATE PROCEDURE.

You must have the ALTER ROUTINE privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 24.2.2, “Stored Routines and MySQL Privileges”.

13.1.8 ALTER SERVER Syntax

ALTER SERVER server_name
  OPTIONS (option [, option] ...)

Alters the server information for server_name, adjusting any of the options permitted in the CREATE SERVER statement. The corresponding fields in the mysql.servers table are updated accordingly. This statement requires the SUPER privilege.

For example, to update the USER option:

ALTER SERVER s OPTIONS {USER 'sally'};

ALTER_SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.
ALTER SERVER is not written to the binary log, regardless of the logging format that is in use.

13.1.9 ALTER TABLE Syntax

ALTER TABLE tbl_name
  [ alter_specification [, alter_specification] ... ]
  [ partition_options ]

alter_specification:
  table_options
  | ADD [COLUMN] col_name column_definition
  [ FIRST | AFTER col_name ]
  | ADD [COLUMN] (col_name column_definition,...)
  | ADD [INDEX|KEY] [index_name]
  [ index_type ] (key_part,...) [index_option] ...
  | ADD [FULLTEXT|SPATIAL] [INDEX|KEY] [index_name]
  (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
  [ index_type ] (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] UNIQUE [INDEX|KEY]
  [index_name] [index_type] (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (col_name,...)
  reference_definition
  | ADD check_constraint_definition
  | DROP CHECK symbol
  | ALTER CHECK symbol [NOT] ENFORCED
  | ALGORITHM [=] {DEFAULT|INSTANT|INPLACE|COPY}
  | ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
  | ALTER INDEX index_name {VISIBLE | INVISIBLE}
  | CHANGE [COLUMN] old_col_name new_col_name column_definition
  [ FIRST | AFTER col_name ]
  | [DEFAULT] CHARACTER SET [COLLATE [=] collation_name]
  | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
  | [DISABLE] | [ENABLE] KEYS
  | [DISCARD] | [IMPORT] TABLESPACE
  | DROP [COLUMN] col_name
  | DROP [INDEX|KEY] index_name
  | DROP PRIMARY KEY
  | DROP FOREIGN KEY fk_symbol
  | FORCE
  | LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
  | MODIFY [COLUMN] col_name column_definition
  [ FIRST | AFTER col_name ]
  | ORDER BY col_name [, col_name] ...
  | RENAME COLUMN old_col_name TO new_col_name
  | RENAME (INDEX|KEY) old_index_name TO new_index_name
  | RENAME [TO AS] new_tbl_name
  | [WITHOUT|WITH] VALIDATION
  | ADD PARTITION (partition_definition)
  | DROP PARTITION partition_names
  | DISCARD PARTITION {partition_names | ALL} TABLESPACE
  | IMPORT PARTITION {partition_names | ALL} TABLESPACE
  | TRUNCATE PARTITION {partition_names | ALL}
  | COALESCE PARTITION number
  | REORGANIZE PARTITION partition_names INTO (partition_definitions)
  | EXCHANGE PARTITION partition_name WITH TABLE tbl_name
  [ (WITH|WITHOUT) VALIDATION ]
  | ANALYZE PARTITION {partition_names | ALL}
  | CHECK PARTITION {partition_names | ALL}
  | OPTIMIZE PARTITION {partition_names | ALL}
  | REBUILD PARTITION {partition_names | ALL}
  | REPAIR PARTITION {partition_names | ALL}
  | REMOVE PARTITIONING
### ALTER TABLE Syntax

**key_part:** 
\[\text{col}_\text{name} \ [\text{length}] | \text{expr} \] \ [ASC | DESC]

**index_type:**
- USING (BTREE | HASH)

**index_option:**
- KEY_BLOCK_SIZE \[\text{value}\]
- WITH PARSER \text{parser}_\text{name}
- COMMENT \text{'string'}
- [VISIBLE | INVISIBLE]

**check_constraint_definition:**
- [CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED]

**table_options:**
- \text{table}_\text{option} [[[,] \text{table}_\text{option}]] ...

**table_option:**
- AUTO_INCREMENT \[\text{value}\]
- AVG_ROW_LENGTH \[\text{value}\]
- [DEFAULT] CHARACTER SET \[\text{charset}_\text{name}\]
- CHECKSUM \[\{0 | 1\}\]
- [DEFAULT] COLLATE \[\text{collation}_\text{name}\]
- COMMENT \[\text{'string'}\]
- COMPRESSION \[\{'ZLIB'|'LZ4'|'NONE'\}]
- CONNECTION \[\text{'connect}_\text{string'}\]
- DATA DIRECTORY \[\text{'absolute path to directory'}\]
- DELAY_KEY_WRITE \[\{0 | 1\}\]
- ENCRYPTION \[\{'Y'|'N'\}]
- ENGINE \[\text{engine}_\text{name}\]
- INSERT_METHOD \[\{NO | FIRST | LAST\}]
- KEY_BLOCK_SIZE \[\text{value}\]
- MAX_ROWS \[\text{value}\]
- MIN_ROWS \[\text{value}\]
- PACK_KEYS \[\{0 | 1 | DEFAULT\}]
- PASSWORD \[\text{'string'}\]
- ROW_FORMAT \[DEFAULT|DYNAMIC|FIXED|COMPRESSED|REDUNDANT|COMPACT\]
- CHECK_AUTO_RECALC \[\{DEFAULT\} \{0 | 1\}\]
- CHECK_PERSISTENT \[\{DEFAULT\} \{0 | 1\}\]
- CHECK_SAMPLE_PAGES \[\text{value}\]
- TABLESPACE \text{tablespace}_\text{name} \{STORAGE \{DISK|MEmory|DEFAULT\}\}
- UNION \[\{tbl_name, tbl_name\}...\]

**partition_options:**
- (see CREATE TABLE options)

### ALTER TABLE

ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use ALTER TABLE, you need ALTER, CREATE, and INSERT privileges for the table. Renaming a table requires ALTER and DROP on the old table, ALTER, CREATE, and INSERT on the new table.

- Following the table name, specify the alterations to be made. If none are given, ALTER TABLE does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the CREATE TABLE statement. column_definition clauses use the same syntax for ADD and CHANGE as for CREATE TABLE. For more information, see Section 13.1.20, “CREATE TABLE Syntax”.

- The word COLUMN is optional and can be omitted, except for RENAME COLUMN (to distinguish a column-renaming operation from the RENAME table-renaming operation).
ALTER TABLE Syntax

- Multiple ADD, ALTER, DROP, and CHANGE clauses are permitted in a single ALTER TABLE statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per ALTER TABLE statement. For example, to drop multiple columns in a single statement, do this:

  ```sql
  ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
  ```

- If a storage engine does not support an attempted ALTER TABLE operation, a warning may result. Such warnings can be displayed with SHOW WARNINGS. See Section 13.7.6.40, “SHOW WARNINGS Syntax”. For information on troubleshooting ALTER TABLE, see Section B.6.6.1, “Problems with ALTER TABLE”.

- For information about generated columns, see Section 13.1.9.2, “ALTER TABLE and Generated Columns”.

- For usage examples, see Section 13.1.9.3, “ALTER TABLE Examples”.

- With the mysql_info() C API function, you can find out how many rows were copied by ALTER TABLE. See Section 28.7.7.36, “mysql_info()”.

There are several additional aspects to the ALTER TABLE statement, described under the following topics in this section:

- Table Options
- Performance and Space Requirements
- Concurrency Control
- Adding and Dropping Columns
- Renaming, Redefining, and Reordering Columns
- Primary Keys and Indexes
- Foreign Keys and Other Constraints
- Changing the Character Set
- Discarding and Importing InnoDB Tablespaces
- Row Order for MyISAM Tables
- Partitioning Options

**Table Options**

`table_options` signifies table options of the kind that can be used in the CREATE TABLE statement, such as ENGINE, AUTO_INCREMENT, AVG_ROW_LENGTH, MAX_ROWS, ROW_FORMAT, or TABLESPACE.

For descriptions of all table options, see Section 13.1.20, “CREATE TABLE Syntax”. However, ALTER TABLE ignores DATA DIRECTORY and INDEX DIRECTORY when given as table options. ALTER TABLE permits them only as partitioning options, and requires that you have the FILE privilege.

Use of table options with ALTER TABLE provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an InnoDB table, this statement changes its storage engine to InnoDB:
ALTER TABLE t1 ENGINE = InnoDB;

• See Section 15.6.1.3, “Converting Tables from MyISAM to InnoDB” for considerations when switching tables to the InnoDB storage engine.

• When you specify an ENGINE clause, ALTER TABLE rebuilds the table. This is true even if the table already has the specified storage engine.

• Running ALTER TABLE tbl_name ENGINE=INNODB on an existing InnoDB table performs a "null" ALTER TABLE operation, which can be used to defragment an InnoDB table, as described in Section 15.11.4, “Defragmenting a Table”. Running ALTER TABLE tbl_name FORCE on an InnoDB table performs the same function.

• ALTER TABLE tbl_name ENGINE=INNODB and ALTER TABLE tbl_name FORCE use online DDL. For more information, see Section 15.12, “InnoDB and Online DDL”.

• The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the NO_ENGINE_SUBSTITUTION SQL mode, as described in Section 5.1.11, “Server SQL Modes”.

• To prevent inadvertent loss of data, ALTER TABLE cannot be used to change the storage engine of a table to MERGE or BLACKHOLE.

• To change the InnoDB table to use compressed row-storage format:

  ALTER TABLE t1 ROW_FORMAT = COMPRESSED;

• To enable or disable encryption for an InnoDB table in a file-per-table tablespace:

  ALTER TABLE t1 ENCRYPTION='Y';
  ALTER TABLE t1 ENCRYPTION='N';

  A keyring plugin must be installed and configured to use the ENCRYPTION option. For more information, see Section 15.6.3.9, “Tablespace Encryption”.

• To reset the current auto-increment value:

  ALTER TABLE t1 AUTO_INCREMENT = 13;

  You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the AUTO_INCREMENT column, the value is reset to the current maximum AUTO_INCREMENT column value plus one.

• To change the default table character set:

  ALTER TABLE t1 CHARACTER SET = utf8;

  See also Changing the Character Set.

• To add (or change) a table comment:

  ALTER TABLE t1 COMMENT = 'New table comment';
ALTER TABLE Syntax

- Use `ALTER TABLE` with the `TABLESPACE` option to move InnoDB tables between existing general tablespaces, file-per-table tablespaces, and the system tablespace. See Moving Tables Between Tablespaces Using `ALTER TABLE`.

- `ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

- `ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

- The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

- For more information about the capabilities and limitations of the `TABLESPACE` option, see `CREATE TABLE`.

- MySQL NDB Cluster 8.0 supports setting `NDB_TABLE` options for controlling a table’s partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an `ALTER TABLE` statement in the same manner as for `CREATE TABLE`, as shown in this example:

  ```sql
  ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
  ```

  Bear in mind that `ALTER TABLE ... COMMENT ...` discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

  To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the `INFORMATION_SCHEMA.TABLES` table.

Performance and Space Requirements

`ALTER TABLE` operations are processed using one of the following algorithms:

- `COPY`: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

- `INPLACE`: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

- `INSTANT`: Operations only modify metadata in the data dictionary. No exclusive metadata locks are taken on the table during preparation and execution, and table data is unaffected, making operations instantaneous. Concurrent DML is permitted. (Introduced in MySQL 8.0.12)

The `ALGORITHM` clause is optional. If the `ALGORITHM` clause is omitted, MySQL uses `ALGORITHM=INSTANT` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=INPLACE` is used. If `ALGORITHM=INPLACE` is not supported, `ALGORITHM=COPY` is used.

Specifying an `ALGORITHM` clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying `ALGORITHM=DEFAULT` is the same as omitting the `ALGORITHM` clause.

`ALTER TABLE` operations that use the `COPY` algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the `ALTER TABLE` operation executes, the original table is readable by other sessions (with the exception noted shortly).
ALTER TABLE Syntax

Updates and writes to the table started after the ALTER TABLE operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a RENAME TO operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that ALTER TABLE blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An ALTER TABLE operation that uses the COPY algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of LOCK=SHARED (allow queries but not DML). You can further restrict concurrency for operations that support the LOCK clause by specifying LOCK=EXCLUSIVE, which prevents DML and queries. For more information, see Concurrency Control.

To force use of the COPY algorithm for an ALTER TABLE operation that would otherwise not use it, specify ALGORITHM=COPY or enable the old_alter_table system variable. If there is a conflict between the old_alter_table setting and an ALGORITHM clause with a value other than DEFAULT, the ALGORITHM clause takes precedence.

For InnoDB tables, an ALTER TABLE operation that uses the COPY algorithm on a table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 15.12.3, “Online DDL Space Requirements”.

ALTER TABLE operations that support the INPLACE algorithm include:

- ALTER TABLE operations supported by the InnoDB online DDL feature. See Section 15.12.1, “Online DDL Operations”.

- Renaming a table. MySQL renames files that correspond to the table tbl_name without making a copy. (You can also use the RENAME TABLE statement to rename tables. See Section 13.1.36, “RENAME TABLE Syntax”). Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- Operations that only modify table metadata. These operations are immediate because the server does not touch table contents. Metadata-only operations include:
  - Renaming a column.
  - Changing the default value of a column (except for NDB tables).
  - Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
  - Changing the definition of a spatial column to remove the SRID attribute. (Adding or changing an SRID attribute does require a rebuild and cannot be done in place because the server must verify that all values have the specified SRID value.)
  - As of MySQL 8.0.14, changing a column character set, when these conditions apply:
ALTER TABLE Syntax

- The column data type is **CHAR, VARCHAR, a TEXT type, or ENUM.**
- The character set change is from **utf8mb3 to utf8mb4,** or any character set to **binary.**
- There is no index on the column.
- As of MySQL 8.0.14, changing a generated column, when these conditions apply:
  - For **InnoDB** tables, statements that modify generated stored columns but do not change their type, expression, or nullability.
  - For non-**InnoDB** tables, statements that modify generated stored or virtual columns but do not change their type, expression, or nullability.

An example of such a change is a change to the column comment.

- Renaming an index.
- Adding or dropping a secondary index, for **InnoDB** and **NDB** tables. See **Section 15.12.1, “Online DDL Operations”**.

For **NDB** tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See **Section 22.5.14, “Online Operations with ALTER TABLE in NDB Cluster”**.

- Modifying index visibility with an **ALTER INDEX** operation.
- Column modifications of tables containing generated columns that depend on columns with a **DEFAULT** value if the modified columns are not involved in the generated column expressions. For example, changing the **NULL** property of a separate column can be done in place without a table rebuild.

**ALTER TABLE** operations that support the **INSTANT** algorithm include:

- Adding a column. This feature is referred to as “Instant **ADD COLUMN**”. Limitations apply. See **Section 15.12.1, “Online DDL Operations”**.
- Adding or dropping a virtual column.
- Adding or dropping a column default value.
- Modifying the definition of an **ENUM** or **SET** column. The same restrictions apply as described above for **ALGORITHM=INSTANT**.
- Changing the index type.
- Renaming a table. The same restrictions apply as described above for **ALGORITHM=INSTANT**.

For more information about operations that support **ALGORITHM=INSTANT**, see **Section 15.12.1, “Online DDL Operations”**.

**ALTER TABLE** upgrades MySQL 5.5 temporal columns to 5.6 format for **ADD COLUMN, CHANGE COLUMN, MODIFY COLUMN, ADD INDEX,** and **FORCE** operations. This conversion cannot be done using the **INPLACE** algorithm because the table must be rebuilt, so specifying **ALGORITHM=INPLACE** in these cases results in an error. Specify **ALGORITHM=COPY** if necessary.

If an **ALTER TABLE** operation on a multicolumn index used to partition a table by **KEY** changes the order of the columns, it can only be performed using **ALGORITHM=COPY**.
ALTER TABLE Syntax

The **WITHOUT VALIDATION** and **WITH VALIDATION** clauses affect whether **ALTER TABLE** performs an in-place operation for virtual generated column modifications. See Section 13.1.9.2, "ALTER TABLE and Generated Columns".

NDB Cluster 8.0 supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 22.5.14, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

**ALTER TABLE** with **DISCARD ... PARTITION ... TABLESPACE** or **IMPORT ... PARTITION ... TABLESPACE** does not create any temporary tables or temporary partition files.

**ALTER TABLE** with **ADD PARTITION**, **DROP PARTITION**, **COALESCE PARTITION**, **REBUILD PARTITION**, or **REORGANIZE PARTITION** does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

**ADD** or **DROP** operations for **RANGE** or **LIST** partitions are immediate operations or nearly so. **ADD** or **COALESCE** operations for **HASH** or **KEY** partitions copy data between all partitions, unless **LINEAR HASH** or **LINEAR KEY** was used; this is effectively the same as creating a new table, although the **ADD** or **COALESCE** operation is performed partition by partition. **REORGANIZE** operations copy only changed partitions and do not touch unchanged ones.

For **MyISAM** tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the **myisam_sort_buffer_size** system variable to a high value.

**Concurrency Control**

For **ALTER TABLE** operations that support it, you can use the **LOCK** clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available.

Only **LOCK = DEFAULT** is permitted for operations that use **ALGORITHM=INSTANT**. The other **LOCK** clause parameters are not applicable.

The parameters for the **LOCK** clause are:

- **LOCK = DEFAULT**
  
  Maximum level of concurrency for the given **ALGORITHM** clause (if any) and **ALTER TABLE** operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- **LOCK = NONE**
  
  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- **LOCK = SHARED**
  
  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given **ALGORITHM** clause (if any) and **ALTER TABLE** operation. If concurrent reads are not supported, an error occurs.

- **LOCK = EXCLUSIVE**
Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

### Adding and Dropping Columns

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For `ALTER TABLE ... ADD`, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error. For details, see Section 17.1.3.6, “Restrictions on Replication with GTIDs”.

### Renaming, Redefining, and Reordering Columns

The `CHANGE`, `MODIFY`, `RENAME COLUMN`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE:**
  - Can rename a column and change its definition, or both.
  - Has more capability than `MODIFY` or `RENAME COLUMN`, but at the expense of convenience for some operations. `CHANGE` requires naming the column twice if not renaming it, and requires respecifying the column definition if only renaming it.
  - With `FIRST` or `AFTER`, can reorder columns.

- **MODIFY:**
  - Can change a column definition but not its name.
  - More convenient than `CHANGE` to change a column definition without renaming it.
  - With `FIRST` or `AFTER`, can reorder columns.

- **RENAME COLUMN:**
  - Can change a column name but not its definition.
  - More convenient than `CHANGE` to rename a column without changing its definition.

- **ALTER:** Used only to change a column default value.

`CHANGE` is a MySQL extension to standard SQL. `MODIFY` and `RENAME COLUMN` are MySQL extensions for Oracle compatibility.
To alter a column to change both its name and definition, use \texttt{CHANGE}, specifying the old and new names and the new definition. For example, to rename an \texttt{INT NOT NULL} column from \texttt{a} to \texttt{b} and change its definition to use the \texttt{BIGINT} data type while retaining the \texttt{NOT NULL} attribute, do this:

\begin{verbatim}
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
\end{verbatim}

To change a column definition but not its name, use \texttt{CHANGE} or \texttt{MODIFY}. With \texttt{CHANGE}, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column \texttt{b}, do this:

\begin{verbatim}
ALTER TABLE t1 CHANGE b b INT NOT NULL;
\end{verbatim}

\texttt{MODIFY} is more convenient to change the definition without changing the name because it requires the column name only once:

\begin{verbatim}
ALTER TABLE t1 MODIFY b INT NOT NULL;
\end{verbatim}

To change a column name but not its definition, use \texttt{CHANGE} or \texttt{RENAME COLUMN}. With \texttt{CHANGE}, the syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an \texttt{INT NOT NULL} column from \texttt{b} to \texttt{a}, do this:

\begin{verbatim}
ALTER TABLE t1 CHANGE b a INT NOT NULL;
\end{verbatim}

\texttt{RENAME COLUMN} is more convenient to change the name without changing the definition because it requires only the old and new names:

\begin{verbatim}
ALTER TABLE t1 RENAME COLUMN b TO a;
\end{verbatim}

In general, you cannot rename a column to a name that already exists in the table. However, this is sometimes not the case, such as when you swap names or move them through a cycle. If a table has columns named \texttt{a}, \texttt{b}, and \texttt{c}, these are valid operations:

\begin{verbatim}
-- swap a and b
ALTER TABLE t1 RENAME COLUMN a TO b,
   RENAME COLUMN b TO a;
-- "rotate" a, b, c through a cycle
ALTER TABLE t1 RENAME COLUMN a TO b,
   RENAME COLUMN b TO c,
   RENAME COLUMN c TO a;
\end{verbatim}

For column definition changes using \texttt{CHANGE} or \texttt{MODIFY}, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as \texttt{PRIMARY KEY} or \texttt{UNIQUE}. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column \texttt{col1} is defined as \texttt{INT UNSIGNED DEFAULT 1 COMMENT 'my column'} and you modify the column as follows, intending to change only \texttt{INT} to \texttt{BIGINT}:

\begin{verbatim}
ALTER TABLE t1 MODIFY col1 BIGINT;
\end{verbatim}

That statement changes the data type from \texttt{INT} to \texttt{BIGINT}, but it also drops the \texttt{UNSIGNED}, \texttt{DEFAULT}, and \texttt{COMMENT} attributes. To retain them, the statement must include them explicitly:

\begin{verbatim}
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
\end{verbatim}

For data type changes using \texttt{CHANGE} or \texttt{MODIFY}, MySQL tries to convert existing column values to the new type as well as possible.
Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see Section 5.1.11, "Server SQL Modes").

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including invisible indexes and disabled `MyISAM` indexes.
- Foreign keys that refer to the old column.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in Section 11.7, "Data Type Default Values".

Primary Keys and Indexes

`DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, "Primary Key Optimization".

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.27, "DROP INDEX Syntax". To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.15, "CREATE INDEX Syntax". The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see Section 13.1.15, "CREATE INDEX Syntax".

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. `old_index_name` must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. `new_index_name` is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`. 
If you use `ALTER TABLE` on a MyISAM table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For MyISAM tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. MyISAM does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.6.22, "SHOW INDEX Syntax".

The `ALTER INDEX` operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see Section 8.3.12, "Invisible Indexes".

**Foreign Keys and Other Constraints**

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB and NDB storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See Section 15.6.1.5, "InnoDB and FOREIGN KEY Constraints". For other storage engines, the clauses are parsed but ignored.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...) ...
```

**Important**

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

**Note**

Partitioned InnoDB tables do not support foreign keys. This restriction does not apply to NDB tables, including those explicitly partitioned by `[LINEAR] KEY`. For more information, see Section 23.6.2, “Partitioning Limitations Relating to Storage Engines”.

MySQL Server and NDB Cluster both support the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but not for `ALTER TABLE ... ALGORITHM=COPY`. 

---

2153
The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. It also prohibits changes to the data type of such columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “tbl_name_ibfk_” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “tbl_name_ibfk_” as internally generated names.

Prior to MySQL 8.0.16, `ALTER TABLE` permits only the following limited version of `CHECK` constraint-adding syntax, which is parsed and ignored:

```
ADD CHECK (expr)
```

As of MySQL 8.0.16, `ALTER TABLE` permits `CHECK` constraints for existing tables to be added, dropped, or altered:

- Add a new constraint:

```
ALTER TABLE tbl_name
    ADD CONSTRAINT [symbol] CHECK (expr) [[NOT] ENFORCED];
```

The meaning of constraint syntax elements is the same as for `CREATE TABLE`. See Section 13.1.20.7, “CHECK Constraints”.

- Drop an existing constraint named `symbol`:

```
ALTER TABLE tbl_name
    DROP CHECK symbol;
```

- Alter whether an existing constraint named `symbol` is enforced:

```
ALTER TABLE tbl_name
    ALTER CHECK symbol [NOT] ENFORCED;
```

The `DROP CHECK` and `ALTER CHECK` clauses are MySQL extensions to standard SQL.

If a table alteration causes a violation of an enforced `CHECK` constraint, an error occurs and the table is not modified. Examples of operations for which an error occurs:

- Attempts to add the `AUTO_INCREMENT` attribute to a column that is used in a `CHECK` constraint.

- Attempts to add an enforced `CHECK` constraint or enforce a nonenforced `CHECK` constraint for which existing rows violate the constraint condition.

- Attempts to modify, rename, or drop a column that is used in a `CHECK` constraint, unless that constraint is also dropped in the same statement. Exception: If a `CHECK` constraint refers only to a single column, dropping the column automatically drops the constraint.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated and user-defined `CHECK` constraint names that begin with the string “tbl_name_chk_” to reflect the new table name. MySQL interprets `CHECK` constraint names that begin with the string “tbl_name_chk_” as internally generated names.
Changing the Character Set

To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no COLLATE clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of VARCHAR or one of the TEXT types, CONVERT TO CHARACTER SET changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a TEXT column's length bytes, so MySQL converts the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use CONVERT TO CHARACTER SET. Instead, use MODIFY to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify CONVERT TO CHARACTER SET binary, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer will have a character set and a subsequent CONVERT TO operation will not apply to them.

If charset_name is DEFAULT in a CONVERT TO CHARACTER SET operation, the character set named by the character_set_database system variable is used.

**Warning**

The CONVERT TO operation converts column values between the original and named character sets. This is not what you want if you have a column in one character set (like latin1) but the stored values actually use some other, incompatible character set (like utf8). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the default character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```
The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

**Discarding and Importing InnoDB Tablespaces**

An InnoDB table created in its own file-per-table tablespace can be discarded and imported using the `DISCARD TABLESPACE` and `IMPORT TABLESPACE` options. These options can be used to import a file-per-table tablespace from a backup or to copy a file-per-table tablespace from one database server to another. See Section 15.6.3.7, “Copying Tablespaces to Another Instance”.

**Row Order for MyISAM Tables**

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

![Note]

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

**Partitioning Options**

`partition_options` signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `DISCARD PARTITION`, `IMPORT PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `EXCHANGE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see Section 13.1.20, “CREATE TABLE Syntax”, and Section 13.1.9.1, “ALTER TABLE Partition Operations”. For information about and examples of `ALTER`
TABLE ... EXCHANGE PARTITION statements, see Section 23.3.3, “Exchanging Partitions and Subpartitions with Tables”.

13.1.9.1 ALTER TABLE Partition Operations

Partitioning-related clauses for ALTER TABLE can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a partition_options clause with ALTER TABLE on a partitioned table repartitions the table according to the partitioning scheme defined by the partition_options. This clause always begins with PARTITION BY, and follows the same syntax and other rules as apply to the partition_options clause for CREATE TABLE (for more detailed information, see Section 13.1.20, “CREATE TABLE Syntax”), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (  
id INT,  
year_col INT 
);
```

This table can be partitioned by HASH, using the id column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1  
PARTITION BY HASH(id)  
PARTITIONS 8;
```

MySQL supports an ALGORITHM option with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

The table that results from using an ALTER TABLE ... PARTITION BY statement must follow the same rules as one created using CREATE TABLE ... PARTITION BY. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The CREATE TABLE ... PARTITION BY rules for specifying the number of partitions also apply to ALTER TABLE ... PARTITION BY.

The partition_definition clause for ALTER TABLE ADD PARTITION supports the same options as the clause of the same name for the CREATE TABLE statement. (See Section 13.1.20, “CREATE TABLE Syntax”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (  
id INT,  
year_col INT 
)  
PARTITION BY RANGE (year_col) {  
  PARTITION p0 VALUES LESS THAN (1991),  
  PARTITION p1 VALUES LESS THAN (1995),
```
ALTER TABLE Syntax

PARTITION p2 VALUES LESS THAN (1999);

You can add a new partition p3 to this table for storing values less than 2002 as follows:

ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));

DROP PARTITION can be used to drop one or more RANGE or LIST partitions. This statement cannot be used with HASH or KEY partitions; instead, use COALESCE PARTITION (see later in this section). Any data that was stored in the dropped partitions named in the partition_names list is discarded. For example, given the table t1 defined previously, you can drop the partitions named p0 and p1 as shown here:

ALTER TABLE t1 DROP PARTITION p0, p1;

Note

DROP PARTITION does not work with tables that use the NDB storage engine. See Section 23.3.1, “Management of RANGE and LIST Partitions”, and Section 22.1.7, “Known Limitations of NDB Cluster”.

ADD PARTITION and DROP PARTITION do not currently support IF [NOT] EXISTS.

The DISCARD PARTITION ... TABLESPACE and IMPORT PARTITION ... TABLESPACE options extend the Transportable Tablespace feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (.idb file). The Transportable Tablespace feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;

ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;

When running DISCARD PARTITION ... TABLESPACE and IMPORT PARTITION ... TABLESPACE on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The Transportable Tablespace feature also supports copying or restoring partitioned InnoDB tables (all partitions at once). For additional information, see Section 15.6.3.7, “Copying Tablespaces to Another Instance”, as well as, Transportable Tablespace Examples.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using ALTER TABLE ... REORGANIZE PARTITION; however, this operation copies the partition's data.

To delete rows from selected partitions, use the TRUNCATE PARTITION option. This option takes a list of one or more comma-separated partition names. Consider the table t1 created by this statement:

CREATE TABLE t1 (  id INT,     year_col INT )  PARTITION BY RANGE (year_col) {  PARTITION p0 VALUES LESS THAN (1991),  PARTITION p1 VALUES LESS THAN (1995),
To delete all rows from partition \texttt{p0}, use the following statement:

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION p0;
\end{verbatim}

The statement just shown has the same effect as the following \texttt{DELETE} statement:

\begin{verbatim}
DELETE FROM t1 WHERE year_col < 1991;
\end{verbatim}

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex \texttt{WHERE} conditions if done with \texttt{DELETE} statements. For example, this statement deletes all rows from partitions \texttt{p1} and \texttt{p3}:

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
\end{verbatim}

An equivalent \texttt{DELETE} statement is shown here:

\begin{verbatim}
DELETE FROM t1 WHERE (year_col >= 1991 AND year_col < 1995)
    OR (year_col >= 2003 AND year_col < 2007);
\end{verbatim}

If you use the \texttt{ALL} keyword in place of the list of partition names, the statement acts on all table partitions.

\texttt{TRUNCATE PARTITION} merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the \texttt{INFORMATION_SCHEMA.PARTITIONS} table, using a query such as this one:

\begin{verbatim}
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
\end{verbatim}

\texttt{COALESCE PARTITION} can be used with a table that is partitioned by \texttt{HASH} or \texttt{KEY} to reduce the number of partitions by \texttt{number}. Suppose that you have created table \texttt{t2} as follows:

\begin{verbatim}
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
) PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
\end{verbatim}

To reduce the number of partitions used by \texttt{t2} from 6 to 4, use the following statement:

\begin{verbatim}
ALTER TABLE t2 COALESCE PARTITION 2;
\end{verbatim}

The data contained in the last \texttt{number} partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).
To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the `partition_names` list and supplying a single definition for `partition_definition`.

- To split an existing partition into several partitions. Accomplish this by naming a single partition for `partition_names` and providing multiple `partition_definitions`.

- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

**Note**

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see Section 23.3.1, “Management of RANGE and LIST Partitions”.

- To exchange a table partition or subpartition with a table, use the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see Section 23.3.3, “Exchanging Partitions and Subpartitions with Tables”.

Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see Section 13.7.3, “Table Maintenance Statements”). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see Section 23.3.4, “Maintenance of Partitions”.

*InnoDB* does not currently support per-partition optimization; `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

- `ALTER TABLE ... UPGRADE PARTITIONING` attempts to upgrade a partitioned *InnoDB* table that was created with the old generic partitioning handler to the *InnoDB* native partitioning employed in MySQL 8.0. In addition, the MySQL upgrade procedure checks for such partitioned *InnoDB* tables and attempts to upgrade them to native partitioning.

- `REMOVE PARTITIONING` enables you to remove a table’s partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
• Using the **ENGINE** option with **ALTER TABLE** changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the **InnoDB** and **NDB** storage engines have native partitioning handlers; **NDB** is not currently supported in MySQL 8.0.

It is possible for an **ALTER TABLE** statement to contain a **PARTITION BY** or **REMOVE PARTITIONING** clause in an addition to other alter specifications, but the **PARTITION BY** or **REMOVE PARTITIONING** clause must be specified last after any other specifications.

The **ADD PARTITION**, **DROP PARTITION**, **COALESCE PARTITION**, **REORGANIZE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, and **REPAIR PARTITION** options cannot be combined with other alter specifications in a single **ALTER TABLE**, since the options just listed act on individual partitions. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given **ALTER TABLE** statement: **PARTITION BY**, **ADD PARTITION**, **DROP PARTITION**, **TRUNCATE PARTITION**, **EXCHANGE PARTITION**, **REORGANIZE PARTITION**, or **COALESCE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, **OPTIMIZE PARTITION**, **REBUILD PARTITION**, **REMOVE PARTITIONING**.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions p1 and p2 of table t1 concurrently using a single statement with a single **ANALYZE PARTITION** option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform **ANALYZE** and **CHECK** operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

**REBUILD** operations are currently unsupported for subpartitions. The **REBUILD** keyword is expressly disallowed with subpartitions, and causes **ALTER TABLE** to fail with an error if so used.

**CHECK PARTITION** and **REPAIR PARTITION** operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see Section 23.3.4, “Maintenance of Partitions”.

### 13.1.9.2 ALTER TABLE and Generated Columns

**ALTER TABLE** operations permitted for generated columns are **ADD**, **MODIFY**, and **CHANGE**.

• Generated columns can be added.

```
CREATE TABLE t1 (c1 INT);
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

• The data type and expression of generated columns can be modified.
ALTER TABLE Syntax

- Generated columns can be renamed or dropped, if no other column refers to them.

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

- Nongenerated columns can be altered to stored but not virtual generated columns.

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

- ADD COLUMN is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, ADD COLUMN and DROP COLUMN are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other ALTER TABLE operations.

- For partitioned tables, ADD COLUMN and DROP COLUMN are not in-place operations for virtual columns.

- InnoDB supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see Section 13.1.20.10, “Secondary Indexes and Generated Columns”.

- When a VIRTUAL generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression will not be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, ALTER TABLE supports WITHOUT VALIDATION and WITH VALIDATION clauses:

- With WITHOUT VALIDATION (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.

- With WITH VALIDATION, ALTER TABLE copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.
ALTER TABLE Syntax

- *WITHOUT VALIDATION* and *WITH VALIDATION* are permitted only with *ADD COLUMN*, *CHANGE COLUMN*, and *MODIFY COLUMN* operations. Otherwise, an *ER_WRONG_USAGE* error occurs.

- If expression evaluation causes truncation or provides incorrect input to a function, the *ALTER TABLE* statement terminates with an error and the DDL operation is rejected.

- An *ALTER TABLE* statement that changes the default value of a column *col_name* may also change the value of a generated column expression that refers to the column using *col_name*, which may change the value of a generated column expression that refers to the column using DEFAULT(*col_name*). For this reason, *ALTER TABLE* operations that change the definition of a column cause a table rebuild if any generated column expression uses DEFAULT().

13.1.9.3 ALTER TABLE Examples

Begin with a table *t1* created as shown here:

```
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from *t1* to *t2*:

```
ALTER TABLE t1 RENAME t2;
```

To change column *a* from INTEGER to TINYINT NOT NULL (leaving the name the same), and to change column *b* from CHAR(10) to CHAR(20) as well as renaming it from *b* to *c*:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new TIMESTAMP column named *d*:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column *d* and a UNIQUE index on column *a*:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column *c*:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new AUTO_INCREMENT integer column named *c*:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
ADD PRIMARY KEY (c);
```

We indexed *c* (as a PRIMARY KEY) because AUTO_INCREMENT columns must be indexed, and we declare *c* as NOT NULL because primary key columns cannot be NULL.

For *NDB* tables, it is also possible to change the storage type used for a table or column. For example, consider an *NDB* table created as shown here:

```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
```
 ALTER TABLE Syntax

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```sql
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE t1
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```sql
mysql> CREATE TABLE t3 (c1 INT, c2 INT) TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```sql
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:
When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, all columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```sql
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

### 13.1.10 ALTER TABLESPACE Syntax

```sql
ALTER [UNDO] TABLESPACE `tablespace_name`
NDB only:
  {ADD|DROP} DATAFILE 'file_name'
  [INITIAL_SIZE [\=] size]
  [WAIT]
InnoDB and NDB:
  [RENAME TO `tablespace_name`]
```
ALTER TABLESPACE Syntax

<table>
<thead>
<tr>
<th>InnoDB only:</th>
</tr>
</thead>
<tbody>
<tr>
<td>[SET {ACTIVE</td>
</tr>
<tr>
<td>[ENCRYPTION [-] {'Y'</td>
</tr>
</tbody>
</table>

**InnoDB and NDB:**

- [ENGINE [-] *engine_name*]

This statement is used with **NDB** and **InnoDB** tablespaces. It can be used to add a new data file to, or to drop a data file from an **NDB** tablespace. It can also be used to rename an **NDB** Cluster Disk Data tablespace, rename an **InnoDB** general tablespace, encrypt an **InnoDB** general tablespace, or mark an **InnoDB undo** tablespace as active or inactive.

The **UNDO** keyword, introduced in MySQL 8.0.14, is used with the **SET {ACTIVE|INACTIVE}** clause to mark an **InnoDB undo** tablespace as active or inactive. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

The **ADD DATAFILE** variant enables you to specify an initial size for an **NDB** Disk Data tablespace using an **INITIAL_SIZE** clause, where *size* is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

**INITIAL_SIZE** is rounded, explicitly, as for `CREATE TABLESPACE`.

Once a data file has been created, its size cannot be changed; however, you can add more data files to an **NDB** tablespace using additional **ALTER TABLESPACE ... ADD DATAFILE** statements.

When **ALTER TABLESPACE ... ADD DATAFILE** is used with **ENGINE = NDB**, a data file is created on each Cluster data node, but only one row is generated in the **INFORMATION_SCHEMA.FILES** table. See the description of this table, as well as Section 22.5.13.1, “NDB Cluster Disk Data Objects”, for more information. **ADD DATAFILE** is not supported with **InnoDB** tablespaces.

Using **DROP DATAFILE** with **ALTER TABLESPACE** drops the data file '*file_name*' from an **NDB** tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 22.5.13.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with **CREATE TABLESPACE** or **ALTER TABLESPACE.DROP DATAFILE** is not supported with **InnoDB** tablespaces.

**WAIT** is parsed but otherwise ignored. It is intended for future expansion.

The **ENGINE** clause, which specifies the storage engine used by the tablespace, is deprecated and will be removed in a future release. The tablespace storage engine is known by the data dictionary, making the **ENGINE** clause obsolete. If the storage engine is specified, it must match the tablespace storage engine defined in the data dictionary. The only values for *engine_name* compatible with **NDB** tablespaces are **NDB** and **NDBCLUSTER**.

**RENAME TO** operations are implicitly performed in `autocommit` mode, regardless of the `autocommit` setting.

A **RENAME TO** operation cannot be performed while **LOCK TABLES** or **FLUSH TABLES WITH READ LOCK** is in effect for tables that reside in the tablespace.

Exclusive **metadata locks** are taken on tables that reside in a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

The **CREATE TABLESPACE** privilege is required to rename an **InnoDB** general tablespace.
The `ENCRYPTION` option is used to enable or disable page-level data encryption for an InnoDB general tablespace or the `mysql` system tablespace. Option values are not case-sensitive. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption support for the `mysql` system tablespace is available as of MySQL 8.0.16. A keyring plugin must be installed and configured to encrypt a tablespace using the `ENCRYPTION` option.

When a general tablespace or the `mysql` system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

The `INPLACE` algorithm is used when altering the `ENCRYPTION` attribute of a general tablespace or the `mysql` system tablespace. The `INPLACE` algorithm permits concurrent DML on tables that reside in the tablespace. Concurrent DDL is blocked.

For more information, see Section 15.6.3.9, “Tablespace Encryption”.

### 13.1.11 ALTER VIEW Syntax

```sql
ALTER VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` (see Section 13.1.23, “CREATE VIEW Syntax”). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SET_USER_ID` or `SUPER` privilege.

### 13.1.12 CREATE DATABASE Syntax

```sql
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
[create_specification] ...
```

`create_specification` options specify database characteristics. Database characteristics are stored in the data dictionary. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. Chapter 10, Character Sets, Collations, Unicode, discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

---

2167
Creating a database directory by manually creating a directory under the data directory (for example, with `mkdir`) is unsupported in MySQL 8.0.

You can also use the `mysqladmin` program to create databases. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

### 13.1.13 CREATE EVENT Syntax

```
CREATE
   [DEFINER = { user | CURRENT_USER }]
EVENT
   [IF NOT EXISTS]
event_name
   ON SCHEDULE schedule
   [ON COMPLETION [NOT] PRESERVE]
   [COMMENT 'string']
   DO event_body;
```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 24.4.2, “Event Scheduler Configuration”.

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. It might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
   ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
   DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table’s `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same database.
schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of event_name, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using schema_name.event_name syntax.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at event execution time. If a user value is given, it should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The default DEFINER value is the user who executes the CREATE EVENT statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

If you specify the DEFINER clause, these rules determine the valid DEFINER user values:

- If you do not have the SET_USER_ID or SUPER privilege, the only permitted user value is your own account, either specified literally or by using CURRENT_USER. You cannot set the definer to some other account.
- If you have the SET_USER_ID or SUPER privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create an event with a nonexistent DEFINER account, an error occurs at event execution time if the account does not exist.

For more information about event security, see Section 24.6, “Access Control for Stored Programs and Views”.

Within an event, the CURRENT_USER() function returns the account used to check privileges at event execution time, which is the DEFINER user. For information about user auditing within events, see Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”.

IF NOT EXISTS has the same meaning for CREATE EVENT as for CREATE TABLE: If an event named event_name already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The ON SCHEDULE clause determines when, how often, and for how long the event_body defined for the event repeats. This clause takes one of two forms:

- AT timestamp is used for a one-time event. It specifies that the event executes one time only at the date and time given by timestamp, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the DATETIME or TIMESTAMP type for this purpose. If the date is in the past, a warning occurs, as shown here:

```sql
mysql> SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2006-02-10 23:59:01 |
+---------------------+
1 row in set (0.04 sec)
```

```sql
mysql> CREATE EVENT e_totals
    -> ON SCHEDULE AT '2006-02-10 23:59:00'
    -> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
```

- AT timestamp is used for a one-time event. It specifies that the event executes one time only at the date and time given by timestamp, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the DATETIME or TIMESTAMP type for this purpose. If the date is in the past, a warning occurs, as shown here:
CREATE EVENT Syntax

CREATE EVENT Syntax

CREATE EVENT statements which are themselves invalid—for whatever reason—fail with an error.

You may use CURRENT_TIMESTAMP to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause + INTERVAL interval. The interval portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in Temporal Intervals, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as + INTERVAL '2:10' MINUTE_SECOND.

You can also combine intervals. For example, AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with + INTERVAL.

To repeat actions at a regular interval, use an EVERY clause. The EVERY keyword is followed by an interval as described in the previous discussion of the AT keyword. (+ INTERVAL is not used with EVERY.) For example, EVERY 6 WEEK means “every six weeks”.

Although + INTERVAL clauses are not permitted in an EVERY clause, you can use the same complex time units permitted in a + INTERVAL.

An EVERY clause may contain an optional STARTS clause. STARTS is followed by a timestamp value that indicates when the action should begin repeating, and may also use + INTERVAL interval to specify an amount of time “from now”. For example, EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE. Not specifying STARTS is the same as using STARTS CURRENT_TIMESTAMP—that is, the action specified for the event begins repeating immediately upon creation of the event.

An EVERY clause may contain an optional ENDS clause. The ENDS keyword is followed by a timestamp value that tells MySQL when the event should stop repeating. You may also use + INTERVAL interval with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using ENDS means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as STARTS does.

You may use STARTS, ENDS, both, or neither in an EVERY clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use
CREATE EVENT Syntax

**SELECT FROM DUAL.** This is true for both **CREATE EVENT** and **ALTER EVENT** statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the **ON SCHEDULE** clause are interpreted using the current session **time_zone** value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the *mysql.event* table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 24.4.4, “Event Metadata”. See also Section 13.7.6.18, “SHOW EVENTS Syntax”, and Section 25.10, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying **ON COMPLETION PRESERVE**. Using **ON COMPLETION NOT PRESERVE** merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the **DISABLE** keyword. Alternatively, you can use **ENABLE** to make explicit the default status, which is active. This is most useful in conjunction with **ALTER EVENT** (see Section 13.1.3, “ALTER EVENT Syntax”).

A third value may also appear in place of **ENABLE** or **DISABLE**; **DISABLE ON SLAVE** is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See Section 17.4.1.16, “Replication of Invoked Features”.

You may supply a comment for an event using a **COMMENT** clause. **comment** may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The **DO** clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section C.1, “Restrictions on Stored Programs”.) For example, the following event **e_hourly** deletes all rows from the **sessions** table once per hour, where this table is part of the **site_activity** schema:

```sql
CREATE EVENT e_hourly ON SCHEDULE EVERY 1 HOUR COMMENT 'Clears out sessions table each hour.' DO DELETE FROM site_activity.sessions;
```

MySQL stores the **sql_mode** system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, **regardless of the current server SQL mode when the event begins executing**.

A **CREATE EVENT** statement that contains an **ALTER EVENT** statement in its **DO** clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as **SELECT** or **SHOW** that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as **SELECT ... INTO** and **INSERT INTO ... SELECT** that store a result. (See the next example in this section for an instance of the latter.)
CREATE EVENT Syntax

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```sql
CREATE EVENT e_daily
  ON SCHEDULE
    EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO
    BEGIN
      INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
      DELETE FROM site_activity.sessions;
    END |

delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See Section 24.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```sql
CREATE EVENT e
  ON SCHEDULE
    EVERY 5 SECOND
  DO
    BEGIN
      DECLARE v INTEGER;
      DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
      SET v = 0;
      WHILE v < 5 DO
        INSERT INTO t1 VALUES (0);
        UPDATE t2 SET s1 = s1 + 1;
        SET v = v + 1;
      END WHILE;
    END |

delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```sql
CREATE EVENT e_call_myproc
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO CALL myproc(5, 27);
```

If an event’s definer has privileges sufficient to set global system variables (see Section 5.1.9.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.
CREATE FUNCTION Syntax

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see Section 24.2.1, “Stored Routine Syntax”. You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.14 CREATE FUNCTION Syntax

The CREATE FUNCTION statement is used to create stored functions and user-defined functions (UDFs):

• For information about creating stored functions, see Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.

• For information about creating user-defined functions, see Section 13.7.4.1, “CREATE FUNCTION Syntax for User-Defined Functions”.

13.1.15 CREATE INDEX Syntax

```
CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (key_part,...)
    [index_option]
    [algorithm_option | lock_option] ...

key_part: (col_name [(length)] | (expr)) [ASC | DESC]

index_option:
    KEY_BLOCK_SIZE [=] value
    index_type
    WITH PARSER parser_name
    COMMENT 'string'
    [VISIBLE | INVISIBLE]

index_type:
    USING {BTREE | HASH}

algorithm_option:
    ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
    LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.20, “CREATE TABLE Syntax”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.9, “ALTER TABLE Syntax”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

InnoDB supports secondary indexes on virtual columns. For more information, see Section 13.20.10, “Secondary Indexes and Generated Columns”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.

An index specification of the form (key_part1, key_part2, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example
(col1, col2, col3) specifies a multiple-column index with index keys consisting of values from col1, col2, and col3.

A key_part specification can end with ASC or DESC to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given. ASC and DESC are not permitted for HASH indexes. As of MySQL 8.0.12, ASC and DESC are not permitted for SPATIAL indexes.

The following sections describe different aspects of the CREATE INDEX statement:

• Column Prefix Key Parts
• Functional Key Parts
• Unique Indexes
• Full-Text Indexes
• Spatial Indexes
• Index Options
• Table Copying and Locking Options

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using col_name(length) syntax to specify an index prefix length:

• Prefixes can be specified for CHAR, VARCHAR, BINARY, and VARBINARY key parts.
• Prefixes must be specified for BLOB and TEXT key parts. Additionally, BLOB and TEXT columns can be indexed only for InnoDB, MyISAM, and BLACKHOLE tables.
• Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for InnoDB tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for InnoDB tables that use the DYNAMIC or COMPRESSED row format. For MyISAM tables, the prefix length limit is 1000 bytes. The NDB storage engine does not support prefixes (see Section 22.1.7.6, “Unsupported or Missing Features in NDB Cluster”).

If a specified index prefix exceeds the maximum column data type size, CREATE INDEX handles the index as follows:

• For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
• For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the name column (assuming that name has a nonbinary string type):
CREATE INDEX part_of_name ON customer (name(10));

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

**Functional Key Parts**

A “normal” index indexes column values or prefixes of column values. For example, in the following table, the index entry for a given `t1` row includes the full `col1` value and a prefix of the `col2` value consisting of its first 10 characters:

```
CREATE TABLE t1 (  
    col1 VARCHAR(10),  
    col2 VARCHAR(20),  
    INDEX (col1, col2(10))  
);
```

MySQL 8.0.13 and higher supports functional key parts that index expression values rather than column or column prefix values. Use of functional key parts enables indexing of values not stored directly in the table. Examples:

```
CREATE TABLE t1 (col1 INT, col2 INT, INDEX func_index ((ABS(col1))));  
CREATE INDEX idx1 ON t1 ((col1 + col2));  
CREATE INDEX idx2 ON t1 ((col1 + col2), (col1 - col2), col1);  
ALTER TABLE t1 ADD INDEX ((col1 * 40) DESC);
```

An index with multiple key parts can mix nonfunctional and functional key parts. 

**ASC** and **DESC** are supported for functional key parts.

Functional key parts must adhere to the following rules. An error occurs if a key part definition contains disallowed constructs.

- In index definitions, enclose expressions within parentheses to distinguish them from columns or column prefixes. For example, this is permitted; the expressions are enclosed within parentheses:
  
  ```
  INDEX ((col1 + col2), (col3 - col4))
  ```

  This produces an error; the expressions are not enclosed within parentheses:

  ```
  INDEX (col1 + col2, col3 - col4)
  ```

- A functional key part cannot consist solely of a column name. For example, this is not permitted:

  ```
  INDEX ((col1), (col2))
  ```

  Instead, write the key parts as nonfunctional key parts, without parentheses:

  ```
  INDEX (col1, col2)
  ```

- A functional key part expression cannot refer to column prefixes. For a workaround, see the discussion of `SUBSTRING()` and `CAST()` later in this section.
• Functional key parts are not permitted in foreign key specifications.

For `CREATE TABLE ... LIKE`, the destination table preserves functional key parts from the original table.

Functional indexes are implemented as hidden virtual generated columns, which has these implications:

• Each functional key part counts against the limit on total number of table columns; see Section C.10.4, "Limits on Table Column Count and Row Size".

• Functional key parts inherit all restrictions that apply to generated columns. Examples:
  
  • Only functions permitted for generated columns are permitted for functional key parts.
  
  • Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.

  For more information about applicable restrictions, see Section 13.1.20.9, “CREATE TABLE and Generated Columns”, and Section 13.1.9.2, “ALTER TABLE and Generated Columns”.

• The virtual generated column itself requires no storage. The index itself takes up storage space as any other index.

`UNIQUE` is supported for indexes that include functional key parts. However, primary keys cannot include functional key parts. A primary key requires the generated column to be stored, but functional key parts are implemented as virtual generated columns, not stored generated columns.

`SPATIAL` and `FULLTEXT` indexes cannot have functional key parts.

If a table contains no primary key, InnoDB automatically promotes the first `UNIQUE NOT NULL` index to the primary key. This is not supported for `UNIQUE NOT NULL` indexes that have functional key parts.

Nonfunctional indexes raise a warning if there are duplicate indexes. Indexes that contain functional key parts do not have this feature.

To remove a column that is referenced by a functional key part, the index must be removed first. Otherwise, an error occurs.

Although nonfunctional key parts support a prefix length specification, this is not possible for functional key parts. The solution is to use `SUBSTRING()` (or `CAST()`, as described later in this section). For a functional key part containing the `SUBSTRING()` function to be used in a query, the `WHERE` clause must contain `SUBSTRING()` with the same arguments. In the following example, only the second `SELECT` is able to use the index because that is the only query in which the arguments to `SUBSTRING()` match the index specification:

```sql
CREATE TABLE tbl (  
  col1 LONGTEXT,  
  INDEX idx1 ({SUBSTRING(col1, 1, 10)})  
) ;  
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 9) = '123456789';  
SELECT * FROM tbl WHERE SUBSTRING(col1, 1, 10) = '1234567890';
```

Functional key parts enable indexing of values that cannot be indexed otherwise, such as `JSON` values. However, this must be done correctly to achieve the desired effect. For example, this syntax does not work:

```sql
CREATE TABLE employees (  
```
CREATE INDEX Syntax

```sql
CREATE TABLE employees (  
data JSON,  
INDEX ((data->>'$.name'))
);
```

The syntax fails because:

- The `->>` operator translates into `JSON_UNQUOTE(JSON_EXTRACT(...))`.
- `JSON_UNQUOTE()` returns a value with a data type of `LONGTEXT`, and the hidden generated column thus is assigned the same data type.
- MySQL cannot index `LONGTEXT` columns specified without a prefix length on the key part, and prefix lengths are not permitted in functional key parts.

To index the `JSON` column, you could try using the `CAST()` function as follows:

```sql
CREATE TABLE employees (  
data JSON,  
INDEX ((CAST(data->>'$.name' AS CHAR(30))))
);
```

The hidden generated column is assigned the `VARCHAR(30)` data type, which can be indexed. But this approach produces a new issue when trying to use the index:

- `CAST()` returns a string with the collation `utf8mb4_0900_ai_ci` (the server default collation).
- `JSON_UNQUOTE()` returns a string with the collation `utf8mb4_bin` (hard coded).

As a result, there is a collation mismatch between the indexed expression in the preceding table definition and the `WHERE` clause expression in the following query:

```sql
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The index is not used because the expressions in the query and the index differ. To support this kind of scenario for functional key parts, the optimizer automatically strips `CAST()` when looking for an index to use, but only if the collation of the indexed expression matches that of the query expression. For an index with a functional key part to be used, either of the following two solutions work (although they differ somewhat in effect):

- **Solution 1. Assign the indexed expression the same collation as `JSON_UNQUOTE()`:**

```sql
CREATE TABLE employees (  
data JSON,  
INDEX idx ((CAST(data->>'$.name' AS CHAR(30)) COLLATE utf8mb4_bin))
);
```

```sql
INSERT INTO employees VALUES  
('{ "name": "james", "salary": 9000 }'),  
('{ "name": "James", "salary": 10000 }'),  
('{ "name": "Mary", "salary": 12000 }'),  
('{ "name": "Peter", "salary": 8000 }');
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The `->>` operator is the same as `JSON_UNQUOTE(JSON_EXTRACT(...))`, and `JSON_UNQUOTE()` returns a string with collation `utf8mb4_bin`. The comparison is thus case sensitive, and only one row matches:
CREATE TABLE employees (  
data JSON,  
INDEX idx ((CAST(data->>'$.name' AS CHAR(30)))))
);

INSERT INTO employees VALUES  
('{ "name": "james", "salary": 9000 }'),  
('{ "name": "James", "salary": 10000 }'),  
('{ "name": "Mary", "salary": 12000 }'),  
('{ "name": "Peter", "salary": 8000 }');

SELECT * FROM employees WHERE CAST(data->>'$.name' AS CHAR(30)) = 'James';

CAST() returns a string with collation `utf8mb4_0900_ai_ci`, so the comparison case insensitive and two rows match:

```
+-------------------+---------------+
| data              | generated_col |
+-------------------+---------------+
| {"name": "james", "salary": 9000} | james         |
| {"name": "James", "salary": 10000} | James         |
+-------------------+---------------+
```

Be aware that although the optimizer supports automatically stripping CAST() with indexed generated columns, the following approach does not work because it produces a different result with and without an index (Bug#27337092):

```
mysql> CREATE TABLE employees (  
    data JSON,  
    generated_col VARCHAR(30) AS (CAST(data->>'$.name' AS CHAR(30)))  
);  
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> INSERT INTO employees (data)  
VALUES ('{"name": "james"}'), ('{"name": "James"}');  
Query OK, 2 rows affected, 1 warning (0.01 sec)  
Records: 2  Duplicates: 0  Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-------------------+---------------+
| data              | generated_col |
+-------------------+---------------+
| {"name": "James"} | James         |
+-------------------+---------------+
1 row in set (0.00 sec)

mysql> ALTER TABLE employees ADD INDEX idx (generated_col);  
Query OK, 0 rows affected, 1 warning (0.03 sec)  
Records: 0  Duplicates: 0  Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-------------------+---------------+
| data              | generated_col |
| {"name": "james"} | james         |
| {"name": "James"} | James         |
+-------------------+---------------+
2 rows in set (0.01 sec)
```
Unique Indexes

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length. A **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as follows:

- `_rowid` refers to the **PRIMARY KEY** column if there is a **PRIMARY KEY** consisting of a single integer column. If there is a **PRIMARY KEY** but it does not consist of a single integer column, `_rowid` cannot be used.

- Otherwise, `_rowid` refers to the column in the first **UNIQUE NOT NULL** index if that index consists of a single integer column. If the first **UNIQUE NOT NULL** index does not consist of a single integer column, `_rowid` cannot be used.

Full-Text Indexes

**FULLTEXT** indexes are supported only for **InnoDB** and **MyISAM** tables and can include only **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation.

Spatial Indexes

The **MyISAM**, **InnoDB**, **NDB**, and **ARCHIVE** storage engines support spatial columns such as **POINT** and **GEOMETRY**. (Section 11.5, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns have these characteristics:

- Available only for **InnoDB** and **MyISAM** tables. Specifying **SPATIAL INDEX** for other storage engines results in an error.

- As of MySQL 8.0.12, an index on a spatial column must be a **SPATIAL** index. The **SPATIAL** keyword is thus optional but implicit for creating an index on a spatial column.

- Available for single spatial columns only. A spatial index cannot be created over multiple spatial columns.

- Indexed columns must be **NOT NULL**.

- Column prefix lengths are prohibited. The full width of each column is indexed.

- Not permitted for a primary key or unique index.

Nonspatial indexes on spatial columns (created with **INDEX**, **UNIQUE**, or **PRIMARY KEY**) have these characteristics:

- Permitted for any storage engine that supports spatial columns except **ARCHIVE**.

- Columns can be **NULL** unless the index is a primary key.

- The index type for a non-**SPATIAL** index depends on the storage engine. Currently, B-tree is used.

- Permitted for a column that can have **NULL** values only for **InnoDB**, **MyISAM**, and **MEMORY** tables.
CREATE INDEX Syntax

Index Options

Following the key part list, index options can be given. An index_option value can be any of the following:

- **KEY_BLOCK_SIZE** [=] value

  For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides a table-level KEY_BLOCK_SIZE value.

  KEY_BLOCK_SIZE is not supported at the index level for InnoDB tables. See Section 13.1.20, "CREATE TABLE Syntax".

- **index_type**

  Some storage engines permit you to specify an index type when creating an index. For example:

  ```sql
  CREATE TABLE lookup (id INT) ENGINE = MEMORY;
  CREATE INDEX id_index ON lookup (id) USING BTREE;
  ```

  Table 13.1, "Index Types Per Storage Engine" shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an index_type clause in index definitions.

  Table 13.1 Index Types Per Storage Engine

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>BTREE</td>
</tr>
<tr>
<td>MyISAM</td>
<td>BTREE</td>
</tr>
<tr>
<td>MEMORY/HEAP</td>
<td>HASH, BTREE</td>
</tr>
<tr>
<td>NDB</td>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

  The index_type clause cannot be used for FULLTEXT INDEX or (prior to MySQL 8.0.12) SPATIAL INDEX specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

  If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name. As of MySQL 8.0.12, this is permitted only for SPATIAL indexes. Prior to 8.0.12, RTREE cannot be specified for any storage engine.

  BTREE indexes are implemented by the NDB storage engine as T-tree indexes.

  **Note**

  For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

  For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS
CREATE INDEX Syntax

[NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes BTREE as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the index_type option before the ON tbl_name clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an index_type option is given in both the earlier and later positions, the final option applies.

TYPE type_name is recognized as a synonym for USING type_name. However, USING is the preferred form.

The following tables show index characteristics for the storage engines that support the index_type option.

Table 13.2 InnoDB Storage Engine Index Characteristics

<td>Table (see note 1)</td>
<td>Table (see note 1)</td>
</tr>
</tbody>
</table>

Table note:

1. **USING HASH** prevents creation of an implicit ordered index.

- **WITH PARSER parser_name**

  This option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. **InnoDB** and **MyISAM** support full-text parser plugins. See **Full-Text Parser Plugins** and **Section 29.2.4.4, “Writing Full-Text Parser Plugins”** for more information.

- **COMMENT 'string'**

  Index definitions can include an optional comment of up to 1024 characters.

The **MERGE_THRESHOLD** for index pages can be configured for individual indexes using the **index_option** **COMMENT** clause of the **CREATE INDEX** statement. For example:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the **MERGE_THRESHOLD** value when a row is deleted or when a row is shortened by an update operation, **InnoDB** attempts to merge the index page with a neighboring index page. The default **MERGE_THRESHOLD** value is 50, which is the previously hardcoded value.

**MERGE_THRESHOLD** can also be defined at the index level and table level using **CREATE TABLE** and **ALTER TABLE** statements. For more information, see **Section 15.8.11, “Configuring the Merge Threshold for Index Pages”**.

- **VISIBLE, INVISIBLE**

  Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see **Section 8.3.12, “Invisible Indexes”**.
CREATE LOGFILE GROUP Syntax

Table Copying and Locking Options

**ALGORITHM** and **LOCK** clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the **ALTER TABLE** statement. For more information, see Section 13.1.9, “ALTER TABLE Syntax”

NDB Cluster supports online operations using the same **ALGORITHM=INPLACE** syntax used with the standard MySQL Server. See Section 22.5.14, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

13.1.16 CREATE LOGFILE GROUP Syntax

```
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] 'string']
  ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single **UNDO** file named `undo_file`. A CREATE LOGFILE GROUP statement has one and only one **ADD UNDOFILE** clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”.

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional **INITIAL_SIZE** parameter sets the **UNDO** file’s initial size; if not specified, it defaults to **128M** (128 megabytes). The optional **UNDO_BUFFER_SIZE** parameter sets the size used by the **UNDO** buffer for the log file group; The default value for **UNDO_BUFFER_SIZE** is **8M** (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes).

Memory used for **UNDO_BUFFER_SIZE** comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

The maximum permitted for **UNDO_BUFFER_SIZE** is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for **INITIAL_SIZE** is 1048576 (1 MB).

The **ENGINE** option determines the storage engine to be used by this log file group, with `engine_name` being the name of the storage engine. In MySQL 8.0, this must be **NDB** (or **NDBCLUSTER**). If **ENGINE** is not set, MySQL tries to use the engine specified by the `default_storage_engine` server system variable (formerly **storage_engine**). In any case, if the engine is not specified as **NDB** or **NDBCLUSTER**, the
CREATE LOGFILE GROUP statement appears to succeed but actually fails to create the log file group, as shown here:

```sql
mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>1478</td>
<td>Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP'</td>
</tr>
</tbody>
</table>
+-------+------+--------------------------------------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
    -> ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

REDO_BUFFER_SIZE, NODEGROUP, WAIT, and COMMENT are parsed but ignored, and so have no effect in MySQL 8.0. These options are intended for future expansion.

When used with ENGINE [ = ] NDB, a log file group and associated UNDO log file are created on each Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
+--------------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+--------------------+----------------------|----------------+
2 rows in set (0.06 sec)
```

CREATE LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 22.5.13, “NDB Cluster Disk Data Tables”.

### 13.1.17 CREATE PROCEDURE and CREATE FUNCTION Syntax

CREATE

[ IN | OUT | INOUT ] param_name type
```

**func_parameter:**

```
param_name type
```

**type:**

Any valid MySQL data type

**characteristic:**

- COMMENT 'string'
- LANGUAGE SQL
- [NOT] DETERMINISTIC
- { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
- SQL SECURITY { DEFINER | INVOKER }

**routine_body:**

Valid SQL routine statement

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The **CREATE FUNCTION** statement is also used in MySQL to support UDFs (user-defined functions). See Section 29.4, “Adding New Functions to MySQL”. A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the **CALL** statement (see Section 13.2.1, “CALL Syntax”). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

**CREATE PROCEDURE** and **CREATE FUNCTION** require the **CREATE ROUTINE** privilege. They might also require the **SET_USER_ID** or **SUPER** privilege, depending on the **DEFINER** value, as described later in this section. If binary logging is enabled, **CREATE FUNCTION** might require the **SUPER** privilege, as described in Section 24.7, “Binary Logging of Stored Programs”.

By default, MySQL automatically grants the **ALTER ROUTINE** and **EXECUTE** privileges to the routine creator. This behavior can be changed by disabling the **automatic_sp_privileges** system variable. See Section 24.2.2, “Stored Routines and MySQL Privileges”.

The **DEFINER** and **SQL SECURITY** clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The **IGNORE_SPACE** SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether **IGNORE_SPACE** is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an **IN** parameter by default. To specify otherwise for a parameter, use the keyword **OUT** or **INOUT** before the parameter name.

**Note**

Specifying a parameter as **IN**, **OUT**, or **INOUT** is valid only for a **PROCEDURE**. For a **FUNCTION**, parameters are always regarded as **IN** parameters.
An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

Routine parameters cannot be referenced in statements prepared within the routine; see Section C.1, “Restrictions on Stored Programs”.

The following example shows a simple stored procedure that uses an `OUT` parameter:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
    -> BEGIN
    -> SELECT COUNT(*) INTO param1 FROM t;
    -> END//
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter ;
mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @a;
+------+
| @a   |
+------+
| 3    |
+------+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See Section 24.1, “Defining Stored Programs”.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
```
CREATE PROCEDURE and CREATE FUNCTION Syntax

-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
<table>
<thead>
<tr>
<th>hello('world')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello, world!</td>
</tr>
</tbody>
</table>
+----------------+
1 row in set (0.00 sec)

Parameter types and function return types can be declared to use any valid data type. The COLLATE attribute can be used if preceded by a CHARACTER SET specification.

The routine_body consists of a valid SQL routine statement. This can be a simple statement such as SELECT or INSERT, or a compound statement written using BEGIN and END. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, “Compound-Statement Syntax”.

MySQL permits routines to contain DDL statements, such as CREATE and DROP. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as COMMIT. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes SELECT statements that do not have an INTO var_list clause and other statements such as SHOW, EXPLAIN, and CHECK TABLE. For statements that can be determined at function definition time to return a result set, a Not allowed to return a result set from a function error occurs (ER_SP_NO_RETSET). For statements that can be determined only at runtime to return a result set, a PROCEDURE %s can't return a result set in the given context error occurs (ER_SP_BADSELECT).

USE statements within stored routines are not permitted. When a routine is invoked, an implicit USE db_name is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section C.1, “Restrictions on Stored Programs”.

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, “CALL Syntax”.

MySQL stores the sql_mode system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, regardless of the current server SQL mode when the routine begins executing.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The COMMENT characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements.

The LANGUAGE characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.
A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither \texttt{DETERMINISTIC} nor \texttt{NOT DETERMINISTIC} is given in the routine definition, the default is \texttt{NOT DETERMINISTIC}. To declare that a function is deterministic, you must specify \texttt{DETERMINISTIC} explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared \texttt{DETERMINISTIC} is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as \texttt{DETERMINISTIC} might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as \texttt{NONDETERMINISTIC} might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the \texttt{DETERMINISTIC} characteristic affects which routine definitions MySQL accepts. See Section 24.7, “Binary Logging of Stored Programs”.

A routine that contains the \texttt{NOW()} function (or its synonyms) or \texttt{RAND()} is nondeterministic, but it might still be replication-safe. For \texttt{NOW()}, the binary log includes the timestamp and replicates correctly. \texttt{RAND()} also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- \texttt{CONTAINS SQL} indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are \texttt{SET @x = 1} or \texttt{DO RELEASE_LOCK('abc')}, which execute but neither read nor write data.

- \texttt{NO SQL} indicates that the routine contains no SQL statements.

- \texttt{READS SQL DATA} indicates that the routine contains statements that read data (for example, \texttt{SELECT}), but not statements that write data.

- \texttt{MODIFIES SQL DATA} indicates that the routine contains statements that may write data (for example, \texttt{INSERT} or \texttt{DELETE}).

The \texttt{SQL SECURITY} characteristic can be \texttt{DEFINER} or \texttt{INVOKER} to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine \texttt{DEFINER} clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is \texttt{DEFINER}. The user who invokes the routine must have the \texttt{EXECUTE} privilege for it, as must the \texttt{DEFINER} account if the routine executes in definer security context.

The \texttt{DEFINER} clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the \texttt{SQL SECURITY DEFINER} characteristic.

If a \texttt{user} value is given for the \texttt{DEFINER} clause, it should be a MySQL account specified as \texttt{'user_name'@'host_name'}, \texttt{CURRENT_USER}, or \texttt{CURRENT_USER()}. The default \texttt{DEFINER} value is the user who executes the \texttt{CREATE PROCEDURE} or \texttt{CREATE FUNCTION} statement. This is the same as specifying \texttt{DEFINER = CURRENT_USER} explicitly.

If you specify the \texttt{DEFINER} clause, these rules determine the valid \texttt{DEFINER} user values:

- If you do not have the \texttt{SET_USER_ID} or \texttt{SUPER} privilege, the only permitted \texttt{user} value is your own account, either specified literally or by using \texttt{CURRENT_USER}. You cannot set the definer to some other account.
CREATE PROCEDURE and CREATE FUNCTION Syntax

- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.

- Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see Section 24.6, "Access Control for Stored Programs and Views".

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. For information about user auditing within stored routines, see Section 6.3.13, "SQL-Based MySQL Account Activity Auditing".

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.

- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

- For character data types, if `CHARACTER SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

  If `CHARACTER SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` and a `COLLATE` attribute for character data parameters.

  If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.
CREATE SERVER Syntax

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see Section 10.3.3, "Database Character Set and Collation".

13.1.18 CREATE SERVER Syntax

```sql
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)
```

**option:**
- `HOST character-literal`
- `DATABASE character-literal`
- `USER character-literal`
- `PASSWORD character-literal`
- `SOCKET character-literal`
- `OWNER character-literal`
- `PORT numeric-literal`

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

**Note**
The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```sql
CREATE SERVER s
    FOREIGN DATA WRAPPER mysql
    OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```sql
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 16.8, "The FEDERATED Storage Engine".
CREATE SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

CREATE SERVER is not written to the binary log, regardless of the logging format that is in use.

### 13.1.19 CREATE SPATIAL REFERENCE SYSTEM Syntax

```sql
CREATE OR REPLACE SPATIAL REFERENCE SYSTEM
    srid srs_attribute ...

CREATE SPATIAL REFERENCE SYSTEM
    [IF NOT EXISTS]
    srid srs_attribute ...

srs_attribute: {
    NAME 'srs_name'
    | DEFINITION 'definition'
    | ORGANIZATION 'org_name' IDENTIFIED BY org_id
    | DESCRIPTION 'description'
}

srid, org_id: 32-bit unsigned integer
```

This statement creates a spatial reference system (SRS) definition and stores it in the data dictionary. The definition can be inspected using the INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS table. This statement requires the SUPER privilege.

If neither OR REPLACE nor IF NOT EXISTS is specified, an error occurs if an SRS definition with the SRID value already exists.

With CREATE OR REPLACE syntax, any existing SRS definition with the same SRID value is replaced, unless the SRID value is used by some column in an existing table. In that case, an error occurs. For example:

```sql
mysql> CREATE OR REPLACE SPATIAL REFERENCE SYSTEM 4326 ...;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query:

```sql
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

With CREATE ... IF NOT EXISTS syntax, any existing SRS definition with the same SRID value causes the new definition to be ignored and a warning occurs.

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with CREATE SPATIAL REFERENCE SYSTEM.
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.
- Users should not create SRSs with SRIDs in the reserved ranges. Doing so runs the risk that the SRIDs will conflict with future SRS definitions distributed with MySQL, with the result that the new system-provided SRSs are not installed for MySQL upgrades or that the user-defined SRSs are overwritten.

Attributes for the statement must satisfy these conditions:

- Attributes can be given in any order, but no attribute can be given more than once.
CREATE TABLE Syntax

- The NAME and DEFINITION attributes are mandatory.
- The NAME srs_name attribute value must be unique. The combination of the ORGANIZATION org_name and org_id attribute values must be unique.
- The NAME srs_name attribute value and ORGANIZATION org_name attribute value cannot be empty or begin or end with whitespace.
- String values in attribute specifications cannot contain control characters, including newline.
- The following table shows the maximum lengths for string attribute values.

Table 13.6 CREATE SPATIAL REFERENCE SYSTEM Attribute Lengths

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>80</td>
</tr>
<tr>
<td>DEFINITION</td>
<td>4096</td>
</tr>
<tr>
<td>ORGANIZATION</td>
<td>256</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>2048</td>
</tr>
</tbody>
</table>

Here is an example CREATE SPATIAL REFERENCE SYSTEM statement. The DEFINITION value is reformatted across multiple lines for readability. (For the statement to be legal, the value actually must be given on a single line.)

CREATE SPATIAL REFERENCE SYSTEM 4120
NAME 'Greek'
ORGANIZATION 'EPSG' IDENTIFIED BY 4120
DEFINITION
  'GEOGCS["Greek",DATUM["Greek",SPHEROID["Bessel 1841", 6377397.155,299.1528128,AUTHORITY["EPSG","7004"]], AUTHORITY["EPSG","6120"],PRIMEM["Greenwich",0, AUTHORITY["EPSG","8901"]],UNIT["degree",0.017453292519943278, AUTHORITY["EPSG","9122"],AXIS["Lat",NORTH],AXIS["Lon",EAST], AUTHORITY["EPSG","4120"]];'

The grammar for SRS definitions is based on the grammar defined in OpenGIS Implementation Specification: Coordinate Transformation Services, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at http://www.opengeospatial.org/standards/ct.

MySQL incorporates these changes to the specification:
- Only the <horz cs> production rule is implemented (that is, geographic and projected SRSs).
- There is an optional, nonstandard <authority> clause for <parameter>. This makes it possible to recognize projection parameters by authority instead of name.
- SRS definitions may not contain newlines.

13.1.20 CREATE TABLE Syntax

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name

CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

By default, tables are created in the default database, using the InnoDB storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

For information about the physical representation of a table, see Section 13.1.20.2, “Files Created by CREATE TABLE”.

The original CREATE TABLE statement, including all specifications and table options are stored by MySQL when the table is created. For more information, see Section 13.1.20.1, “CREATE TABLE Statement Retention”.

There are several aspects to the CREATE TABLE statement, described under the following topics in this section:

- Table Name
- Temporary Tables
- Table Cloning and Copying
- Column Data Types and Attributes
- Indexes, Foreign Keys, and CHECK Constraints
- Table Options
- Table Partitioning

### Table Name

- **tbl_name**

  The table name can be specified as `db_name.tbl_name` to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `mydb`.`mytbl`, not `mydb.mytbl`.

  Rules for permissible table names are given in Section 9.2, “Schema Object Names”.

- **IF NOT EXISTS**

  Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the CREATE TABLE statement.

### Temporary Tables

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see Section 13.1.20.3, “CREATE TEMPORARY TABLE Syntax”.

### Table Cloning and Copying

- **LIKE**
CREATE TABLE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```sql
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see Section 13.1.20.4, “CREATE TABLE ... LIKE Syntax”.

- `[AS] query_expression`

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```sql
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see Section 13.1.20.5, “CREATE TABLE ... SELECT Syntax”.

- `IGNORE|REPLACE`

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see Section 13.1.20.5, “CREATE TABLE ... SELECT Syntax”.

**Column Data Types and Attributes**

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in Section C.10.4, “Limits on Table Column Count and Row Size”.

- `data_type`

  `data_type` represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, Data Types.

  - Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. Prior to MySQL 8.0.13, `DEFAULT` does not apply to the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` types.

  - Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) synonyms) can include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for `CHARACTER SET`. A collation for the character set can be specified with the `COLLATE` attribute, along with any other attributes. For details, see Chapter 10, Character Sets, Collations, Unicode. Example:

    ```sql
    CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
    ```

  MySQL 8.0 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.

  - For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length must be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.15, “CREATE INDEX Syntax”.
Only the InnoDB and MyISAM storage engines support indexing on BLOB and TEXT columns. For example:

```sql
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));```

If a specified index prefix exceeds the maximum column data type size, CREATE TABLE handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).

- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

JSON columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

- NOT NULL | NULL

If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

In MySQL 8.0, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.

- DEFAULT

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit DEFAULT value, see Section 11.7, "Data Type Default Values".

If the NO_ZERO_DATE or NO_ZERO_IN_DATE SQL mode is enabled and a date-valued default is not correct according to that mode, CREATE TABLE produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with NO_ZERO_IN_DATE enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- AUTO_INCREMENT

An integer or floating-point column can have the additional attribute AUTO_INCREMENT. When you insert a value of NULL (recommended) or 0 into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. AUTO_INCREMENT sequences begin with 1.

To retrieve an AUTO_INCREMENT value after inserting a row, use the LAST_INSERT_ID() SQL function or the `mysql_insert_id()` C API function. See Section 12.15, "Information Functions", and Section 28.7.7.38, "mysql_insert_id()".

If the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled, you can store 0 in AUTO_INCREMENT columns as 0 without generating a new sequence value. See Section 5.1.11, "Server SQL Modes".

There can be only one AUTO_INCREMENT column per table, it must be indexed, and it cannot have a DEFAULT value. An AUTO_INCREMENT column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid
CREATE TABLE Syntax

precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an AUTO_INCREMENT column that contains 0.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the AUTO_INCREMENT value for the last inserted row with the following query:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that sql_auto_is_null variable is not set to 0. See Section 5.1.8, “Server System Variables”.

For information about InnoDB and AUTO_INCREMENT, see Section 15.6.1.4, “AUTO_INCREMENT Handling in InnoDB”. For information about AUTO_INCREMENT and MySQL Replication, see Section 17.4.1.1, “Replication and AUTO_INCREMENT”.

• COMMENT

A comment for a column can be specified with the COMMENT option, up to 1024 characters long. The comment is displayed by the SHOW CREATE TABLE and SHOW FULL COLUMNS statements.

• COLUMN_FORMAT

In NDB Cluster, it is also possible to specify a data storage format for individual columns of NDB tables using COLUMN_FORMAT. Permissible column formats are FIXED, DYNAMIC, and DEFAULT. FIXED is used to specify fixed-width storage, DYNAMIC permits the column to be variable-width, and DEFAULT causes the column to use fixed-width or variable-width storage as determined by the column’s data type (possibly overridden by a ROW_FORMAT specifier).

For NDB tables, the default value for COLUMN_FORMAT is FIXED.

COLUMN_FORMAT currently has no effect on columns of tables using storage engines other than NDB. MySQL 8.0 silently ignores COLUMN_FORMAT.

• STORAGE

For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a STORAGE clause. STORAGE DISK causes the column to be stored on disk, and STORAGE MEMORY causes in-memory storage to be used. The CREATE TABLE statement used must still include a TABLESPACE clause:

```sql
mysql> CREATE TABLE t1 (  -> c1 INT STORAGE DISK,  -> c2 INT STORAGE MEMORY  -> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)
```

```sql
mysql> CREATE TABLE t1 (  -> c1 INT STORAGE DISK,  -> c2 INT STORAGE MEMORY  -> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For NDB tables, STORAGE DEFAULT is equivalent to STORAGE MEMORY.
CREATE TABLE Syntax

The `STORAGE` clause has no effect on tables using storage engines other than `NDB`. The `STORAGE` keyword is supported only in the build of `mysqld` that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the `STORAGE` keyword causes a syntax error.

- **GENERATED ALWAYS**

  Used to specify a generated column expression. For information about generated columns, see Section 13.1.20.9, "CREATE TABLE and Generated Columns".

  *Stored generated columns* can be indexed. *InnoDB* supports secondary indexes on *virtual generated columns*. See Section 13.1.20.10, "Secondary Indexes and Generated Columns".

Indexes, Foreign Keys, and CHECK Constraints

Several keywords apply to creation of indexes, foreign keys, and CHECK constraints. For general background in addition to the following descriptions, see Section 13.1.15, "CREATE INDEX Syntax", Section 13.1.20.6, "Using FOREIGN KEY Constraints", and Section 13.1.20.7, "CHECK Constraints".

- **CONSTRAINT symbol**

  The `CONSTRAINT symbol` clause may be given to name a constraint. If the clause is not given, or a `symbol` is not included following the `CONSTRAINT` keyword, MySQL automatically generates a constraint name, with the exception noted below. The `symbol` value, if used, must be unique per schema (database), per constraint type. A duplicate `symbol` results in an error.

  ![Note](https://via.placeholder.com/150)

  If the `CONSTRAINT symbol` clause is not given in a foreign key definition, or a `symbol` is not included following the `CONSTRAINT` keyword, MySQL uses the foreign key index name up to MySQL 8.0.15, and automatically generates a constraint name thereafter.

  The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema.

- **PRIMARY KEY**

  A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

  If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

  In *InnoDB* tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 15.6.2.1, "Clustered and Secondary Indexes".)

  In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.
A **PRIMARY KEY** can be a multiple-column index. However, you cannot create a multiple-column index using the **PRIMARY KEY** key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate **PRIMARY KEY(key_part, ...)** clause.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use ```_rowid``` to refer to the indexed column in SELECT statements, as described in Unique Indexes.

In MySQL, the name of a **PRIMARY KEY** is **PRIMARY**. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (```_2, _3, ...``` ) to make it unique. You can see index names for a table using SHOW INDEX FROM `tbl_name`. See Section 13.7.6.22, “SHOW INDEX Syntax”.

- **KEY | INDEX**

  **KEY** is normally a synonym for **INDEX**. The key attribute **PRIMARY KEY** can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.

- **UNIQUE**

  A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length.

  If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use ```_rowid``` to refer to the indexed column in SELECT statements, as described in Unique Indexes.

- **FULLTEXT**

  A **FULLTEXT** index is a special type of index used for full-text searches. Only the **InnoDB** and **MyISAM** storage engines support **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation. A WITH PARSER clause can be specified as an index_option value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for **FULLTEXT** indexes. **InnoDB** and **MyISAM** support full-text parser plugins. See Full-Text Parser Plugins and Section 29.2.4.4, “Writing Full-Text Parser Plugins” for more information.

- **SPATIAL**

  You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **InnoDB** and **MyISAM** tables, and indexed columns must be declared as **NOT NULL**. See Section 11.5, “Spatial Data Types”.

- **FOREIGN KEY**

  MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition, and reference_option.

  Partitioned tables employing the **InnoDB** storage engine do not support foreign keys. See Section 23.6, “Restrictions and Limitations on Partitioning”, for more information.
CREATE TABLE Syntax

- **CHECK**

  The **CHECK** clause enables the creation of constraints to be checked for data values in table rows. See Section 13.1.20.7, “CHECK Constraints”.

- **key_part**

  - A **key_part** specification can end with **ASC** or **DESC** to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.

  - Prefixes, defined by the **length** attribute, can be up to 767 bytes long for **InnoDB** tables that use the REDUNDANT or COMPACT row format. The prefix length limit is 3072 bytes for **InnoDB** tables that use the DYNAMIC or COMPRESSED row format. For **MyISAM** tables, the prefix length limit is 1000 bytes.

    Prefix limits are measured in bytes. However, prefix lengths for index specifications in **CREATE TABLE**, **ALTER TABLE**, and **CREATE INDEX** statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- **index_type**

  Some storage engines permit you to specify an index type when creating an index. The syntax for the **index_type** specifier is **USING type_name**.

  Example:

  ```
  CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
  ENGINE = MEMORY;
  ```

  The preferred position for **USING** is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- **index_option**

  **index_option** values specify additional options for an index.

  - **KEY_BLOCK_SIZE**

    For **MyISAM** tables, **KEY_BLOCK_SIZE** optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A **KEY_BLOCK_SIZE** value specified for an individual index definition overrides the table-level **KEY_BLOCK_SIZE** value.

    For information about the table-level **KEY_BLOCK_SIZE** attribute, see **Table Options**.

- **WITH PARSER**

  The **WITH PARSER** option can only be used with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. **InnoDB** and **MyISAM** support full-text parser plugins. If you have a **MyISAM** table with an associated full-text parser plugin, you can convert the table to **InnoDB** using **ALTER TABLE**.

- **COMMENT**

  In MySQL 8.0, index definitions can include an optional comment of up to 1024 characters.
You can set the `InnoDB MERGE_THRESHOLD` value for an individual index using the `index_option COMMENT` clause. See Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

For more information about permissible `index_option` values, see Section 13.1.15, “CREATE INDEX Syntax”. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

- `reference_definition`

  For `reference_definition` syntax details and examples, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”. For information specific to foreign keys in `InnoDB`, see Section 15.6.1.5, “InnoDB and FOREIGN KEY Constraints”.

  `InnoDB` and `NDB` tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys are supported. For more detailed information and examples, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”. For information specific to foreign keys in `InnoDB`, see Section 15.6.1.5, “InnoDB and FOREIGN KEY Constraints”.

  For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. See Section 1.8.2.3, “Foreign Key Differences”.

---

**Important**

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, `InnoDB` does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.

MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

- `reference_option`

  For information about the `RESTRICT`, `CASCADE`, `SET NULL`, `NO ACTION`, and `SET DEFAULT` options, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”.
Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- **ENGINE**

  Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is recognized but ignored.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 15, The InnoDB Storage Engine, and in particular Section 15.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 16.2, “The MyISAM Storage Engine”.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 16.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 16.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 16.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 16.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>MERGE</td>
<td>This is a synonym for MEMORY.</td>
</tr>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 22, MySQL NDB Cluster 8.0.</td>
</tr>
</tbody>
</table>

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing `NO_ENGINE_SUBSTITUTION` from the server SQL mode (see Section 5.1.11, “Server SQL Modes”) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the `default_storage_engine` system variable. When `NO_ENGINE_SUBSTITUTION` is disabled, a warning occurs if the storage engine specification is not honored.

- **AUTO_INCREMENT**

  The initial AUTO_INCREMENT value for the table. In MySQL 8.0, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the AUTO_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.
CREATE TABLE Syntax

For engines that support the AUTO_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE tbl_name AUTO_INCREMENT = N to reset the AUTO_INCREMENT value. The value cannot be set lower than the maximum value currently in the column.

- **AVG_ROW_LENGTH**

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the MAX_ROWS and AVG_ROW_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the myisam_data_pointer_size system variable. (See Section 5.1.8, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

Specifies a default character set for the table. CHARSET is a synonym for CHARACTER SET. If the character set name is DEFAULT, the database character set is used.

- **CHECKSUM**

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

- **[DEFAULT] COLLATE**

Specifies a default collation for the table.

- **COMMENT**

A comment for the table, up to 2048 characters long.

You can set the InnoDB MERGE_THRESHOLD value for a table using the table_option COMMENT clause. See Section 15.8.11, “Configuring the Merge Threshold for Index Pages”.

**Setting NDB_TABLE options.** The table comment in a CREATE TABLE that creates an NDB table or an ALTER TABLE statement which alters one can also be used to specify one to four of the NDB_TABLE options NOLOGGING, READ_BACKUP, PARTITION_BALANCE, or FULLY_REPLICATED as a set of name-value pairs, separated by commas if need be, immediately following the string NDB_TABLE= that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```sql
CREATE TABLE t1 (
    c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c2 VARCHAR(100),
    c3 VARCHAR(100)
) ENGINE=NDB
COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";
```

Spaces are not permitted within the quoted string. The string is case-insensitive.
CREATE TABLE Syntax

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available as the `TABLE_COMMENT` column of the MySQL Information Schema `TABLES` table.

This comment syntax is also supported with `ALTER TABLE` statements for NDB tables. Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have had perviously.

Setting the `MERGE_THRESHOLD` option in table comments is not supported for NDB tables (it is ignored).

For complete syntax information and examples, see Section 13.1.20.11, “Setting NDB_TABLE Options”.

• COMPRESSION

The compression algorithm used for page level compression for InnoDB tables. Supported values include Zlib, LZ4, and None. The `COMPRESSION` attribute was introduced with the transparent page compression feature. Page compression is only supported with InnoDB tables that reside in file-per-table tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see Section 15.9.2, “InnoDB Page Compression”.

• CONNECTION

The connection string for a FEDERATED table.

Note
Older versions of MySQL used a `COMMENT` option for the connection string.

• DATA DIRECTORY, INDEX DIRECTORY

For InnoDB, the `DATA DIRECTORY='directory'` clause permits creating a file-per-table tablespace outside of the data directory. The tablespace data file is created in the specified directory, inside a subdirectory with the same name as the schema. The `innodb_file_per_table` variable must be enabled to use the `DATA DIRECTORY` clause. The full directory path must be specified. For more information, see Section 15.6.3.6, “Creating a Tablespace Outside of the Data Directory”.

When creating MyISAM tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a MyISAM table’s data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

You must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

Important
Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the
server with the `--keep_files_on_create` option, in which case MyISAM will not overwrite existing files and returns an error instead.

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing .MYD or .MYI file is found, MyISAM always returns an error. It will not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- **DELAY_KEY_WRITE**

  Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.1.8, “Server System Variables”. (MyISAM only.)

- **ENCRYPTION**

  Set the `ENCRYPTION` option to 'Y' to enable page-level data encryption for an InnoDB table created in a file-per-table tablespace. Option values are not case-sensitive. The `ENCRYPTION` option was introduced with the InnoDB tablespace encryption feature; see Section 15.6.3.9, “Tablespace Encryption”. A keyring plugin must be installed and configured to use the `ENCRYPTION` option.

- **INSERT_METHOD**

  If you want to insert data into a MERGE table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for MERGE tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 16.7, “The MERGE Storage Engine”.

- **KEY_BLOCK_SIZE**

  For MyISAM tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  For InnoDB tables, `KEY_BLOCK_SIZE` specifies the page size in kilobytes to use for compressed InnoDB tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See Section 15.9.1, “InnoDB Table Compression” for more information.

  Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for InnoDB tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

  The `Create_options` column in response to `SHOW TABLE STATUS` reports the actual `KEY_BLOCK_SIZE` used by the table, as does `SHOW CREATE TABLE`.

  InnoDB only supports `KEY_BLOCK_SIZE` at the table level.
The `KEY_BLOCK_SIZE` is not supported with 32KB and 64KB `innodb_page_size` values. InnoDB table compression does not support these page sizes.

InnoDB does not support the `KEY_BLOCK_SIZE` option when creating temporary tables.

- **MAX_ROWS**

  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

  **Important**
  
  The use of `MAX_ROWS` with NDB tables to control the number of table partitions is deprecated. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use `PARTITION_BALANCE` instead; see Setting NDB_TABLE options.

  The NDB storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to insure that NDB allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting $\text{MAX_ROWS} = 2 \times \text{rows}$, where \text{rows} is the number of rows that you expect to insert into the table.

  The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- **MIN_ROWS**

  The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- **PACK_KEYS**

  Takes effect only with MyISAM tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

  If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

  When packing binary number keys, MySQL uses prefix compression:

  - Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

  - The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

  This means that if you have many equal keys on two consecutive rows, all following "same" keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes $\text{storage_size_for_key} + \text{pointer_size}$ (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- **PASSWORD**
This option is unused.

- **ROW_FORMAT**

Defines the physical format in which the rows are stored.

When executing a `CREATE TABLE` statement with *strict mode* disabled, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The actual row format of the table is reported in the `Row_format` and `Create_options` columns in response to `SHOW TABLE STATUS`. `SHOW CREATE TABLE` also reports the actual row format of the table.

Row format choices differ depending on the storage engine used for the table.

For **InnoDB** tables:

- The default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

  If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see Defining the Row Format of a Table.

- For more efficient **InnoDB** storage of data types, especially **BLOB** types, use the `DYNAMIC`. See **DYNAMIC Row Format** for requirements associated with the `DYNAMIC` row format.

- To enable compression for **InnoDB** tables, specify `ROW_FORMAT=COMPRESSED`. The `ROW_FORMAT=COMPRESSED` option is not supported when creating temporary tables. See Section 15.9, “InnoDB Table and Page Compression” for requirements associated with the `COMPRESSED` row format.

- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.

- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.

  - `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, **InnoDB** issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default, **InnoDB** returns an error.

- For additional information about **InnoDB** row formats, see Section 15.10, “InnoDB Row Formats”.

For **MyISAM** tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See Section 16.2.3, “MyISAM Table Storage Formats”.

For **NDB** tables, the default `ROW_FORMAT` is `DYNAMIC`.

- **STATS_AUTO_RECALC**

  Specifies whether to automatically recalculate persistent statistics for an **InnoDB** table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this
CREATE TABLE Syntax

table; with this setting, issue an **ANALYZE TABLE** statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **STATS_PERSISTENT**

  Specifies whether to enable persistent statistics for an InnoDB table. The value **DEFAULT** causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value **1** enables persistent statistics for the table, while the value **0** turns off this feature. After enabling persistent statistics through a **CREATE TABLE** or **ALTER TABLE** statement, issue an **ANALYZE TABLE** statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **STATS_SAMPLE_PAGES**

  The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by **ANALYZE TABLE**. For more information, see Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **TABLESPACE**

  The **TABLESPACE** clause can be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

  ```sql
  CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
  ```

  The general tablespace that you specify must exist prior to using the **TABLESPACE** clause. For information about general tablespaces, see Section 15.6.3.3, “General Tablespaces”.

  The **tablespace_name** is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with “innodb_” are reserved for special use.

  To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

  ```sql
  CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
  ```

  Using **TABLESPACE [=] innodb_system**, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with **ROW_FORMAT=DYNAMIC** to the system tablespace using **TABLESPACE [=] innodb_system**.

  To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

  ```sql
  CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
  ```

  **Note**

  If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

  The **DATA DIRECTORY** clause is permitted with **CREATE TABLE ... TABLESPACE=innodb_file_per_table** but is otherwise not supported for use in combination with the **TABLESPACE** clause.
CREATE TABLE Syntax

Note
Support for TABLESPACE = innodb_file_per_table and TABLESPACE = innodb_temporary clauses with CREATE TEMPORARY TABLE is deprecated as of MySQL 8.0.13 and will be removed in a future version of MySQL.

• UNION

Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 16.7, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note
Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Table Partitioning

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 23, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.9, “ALTER TABLE Syntax”. For more detailed descriptions and examples, see Section 23.3, “Partition Management”.

• PARTITION BY

If used, a partition_options clause begins with PARTITION BY. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to num, where num is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note
The expression (expr) used in a PARTITION BY clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

• HASH(expr)

Hashes one or more columns to create a key for placing and locating rows. expr is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid CREATE TABLE statements using PARTITION BY HASH:

| CREATE TABLE t1 (col1 INT, col2 CHAR(5)) PARTITION BY HASH(col1); |
| CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME) |
You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY HASH.

PARTITION BY HASH uses the remainder of expr divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 23.2.4, “HASH Partitioning”.

The LINEAR keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical AND operations. For discussion and examples of linear hashing, see Section 23.2.4.1, “LINEAR HASH Partitioning”.

• KEY(column_list)

This is similar to HASH, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The column_list argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```sql
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY KEY(col3)
    PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the LINEAR keyword. This has the same effect as with tables that are partitioned by HASH. That is, the partition number is found using the operator rather than the modulus (see Section 23.2.4.1, “LINEAR HASH Partitioning”, and Section 23.2.5, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```sql
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR KEY(col3)
    PARTITIONS 5;
```

The ALGORITHM={1|2} option is supported with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see Section 13.1.9.1, “ALTER TABLE Partition Operations”.

mysqldump in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```sql
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 2 */ /*!50100 ()
PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by KEY into a MySQL 5.6 server previous to version 5.6.11, be sure to consult Changes in MySQL 5.6, before proceeding. (The information found there also applies if you are loading a dump containing KEY partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)
Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- **RANGE(expr)**

In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

---

**Note**

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.0, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

<table>
<thead>
<tr>
<th>Partition Number:</th>
<th>Years Range:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
<tr>
<td>5</td>
<td>2006 and later</td>
</tr>
</tbody>
</table>

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```sql
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES`
**CREATE TABLE Syntax**

*LESS THAN* is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- **RANGE COLUMNS(column_list)**

  This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

  The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

  The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...`. You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (  
a INT NOT NULL,  
b INT NOT NULL )  
PARTITION BY RANGE COLUMNS(a,b) (  
    PARTITION p0 VALUES LESS THAN (10,5),  
    PARTITION p1 VALUES LESS THAN (20,10),  
    PARTITION p2 VALUES LESS THAN (50,MAXVALUE),  
    PARTITION p3 VALUES LESS THAN (65,MAXVALUE),  
    PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)  
);
```

  Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string '1' for a value that matches a column that uses an integer type (you must use the numeral 1 instead), nor can you use the numeral 1 for a value that matches a column that uses a string type (in such a case, you must use a quoted string: '1').

  For more information, see Section 23.2.1, “RANGE Partitioning”, and Section 23.4, “Partition Pruning”.

- **LIST(expr)**

  This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

  `VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:
CREATE TABLE client_firms (  
  id   INT,  
  name VARCHAR(35)  
)
PARTITION BY LIST (id) (  
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),  
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),  
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),  
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)  
);

When using list partitioning, you must define at least one partition using VALUES IN. You cannot use VALUES LESS THAN with PARTITION BY LIST.

Note
For tables partitioned by LIST, the value list used with VALUES IN must consist of integer values only. In MySQL 8.0, you can overcome this limitation using partitioning by LIST COLUMNS, which is described later in this section.

• LIST COLUMNS(column_list)

This variant on LIST facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as WHERE a = 5 AND b = 5 or WHERE a = 1 AND b = 10 AND c = 5). It enables you to specify values in multiple columns by using a list of columns in the COLUMNS clause and a set of column values in each PARTITION ... VALUES IN (value_list) partition definition clause.

The rules governing regarding data types for the column list used in LIST COLUMNS(column_list) and the value list used in VALUES IN(value_list) are the same as those for the column list used in RANGE COLUMNS(column_list) and the value list used in VALUES LESS THAN(value_list), respectively, except that in the VALUES IN clause, MAXVALUE is not permitted, and you may use NULL.

There is one important difference between the list of values used for VALUES IN with PARTITION BY LIST COLUMNS as opposed to when it is used with PARTITION BY LIST. When used with PARTITION BY LIST COLUMNS, each element in the VALUES IN clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the COLUMNS clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the column_list and in the elements making up the value_list is 16.

The table defined by the following CREATE TABLE statement provides an example of a table using LIST COLUMNS partitioning:

CREATE TABLE lc (  
  a INT NULL,  
  b INT NULL  
)
PARTITION BY LIST COLUMNS(a,b) (  
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),  
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),  
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),  
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )  
);  

• PARTITIONS num
The number of partitions may optionally be specified with a PARTITIONS num clause, where num is the number of partitions. If both this clause and any PARTITION clauses are used, num must be equal to the total number of any partitions that are declared using PARTITION clauses.

**Note**

Whether or not you use a PARTITIONS clause in creating a table that is partitioned by RANGE or LIST, you must still include at least one PARTITION VALUES clause in the table definition (see below).

- **SUBPARTITION BY**

  A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional SUBPARTITION BY clause. Subpartitioning may be done by HASH or KEY. Either of these may be LINEAR. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by LIST or RANGE.)

  The number of subpartitions can be indicated using the SUBPARTITIONS keyword followed by an integer value.

- **Rigorous checking of the value used in PARTITIONS or SUBPARTITIONS clauses is applied and this value must adhere to the following rules:**
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, PARTITIONS 0.2E+01 is not permitted, even though 0.2E+01 evaluates to 2. (Bug #15890)

- **partition_definition**

  Each partition may be individually defined using a partition_definition clause. The individual parts making up this clause are as follows:

  - PARTITION partition_name
  
    Specifies a logical name for the partition.

  - VALUES

    For range partitioning, each partition must include a VALUES LESS THAN clause; for list partitioning, you must specify a VALUES IN clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 23, Partitioning, for syntax examples.

  - [STORAGE] ENGINE

    MySQL accepts a [STORAGE] ENGINE option for both PARTITION and SUBPARTITION. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL.

- **COMMENT**
An optional `COMMENT` clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- **DATA DIRECTORY** and **INDEX DIRECTORY**

  `DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the `data_dir` and the `index_dir` must be absolute system path names.

  You must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` partition option.

  Example:

  ```
  CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
  PARTITION BY LIST(YEAR(adate))
  (
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
  );
  ```

  `DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

  One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

  The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect.

- **MAX_ROWS** and **MIN_ROWS**

  May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as "suggestions" to the server and are not hard limits.

- **TABLESPACE**

  May be used to designate an `InnoDB` file-per-table tablespace for the partition by specifying `TABLESPACE 'innodb_file_per_table'`. All partitions must belong to the same storage engine.

  Placing `InnoDB` table partitions in shared `InnoDB` tablespaces is not supported. Shared tablespaces include the `InnoDB` system tablespace and general tablespaces.
The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See Section 23.2.6, “Subpartitioning”.

### Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```sql
CREATE TABLE t1 (  
s1 INT,  
s2 INT AS (EXP(s1)) STORED  
)  
PARTITION BY LIST (s2) {  
  PARTITION p1 VALUES IN (1)  
};
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see Section 23.6.3, “Partitioning Limitations Relating to Functions”). The preceding example demonstrates this technique: `EXP()` cannot be used directly in the `PARTITION BY` clause, but a generated column defined using `EXP()` is permitted.

### 13.1.20.1 CREATE TABLE Statement Retention

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an `ALTER TABLE` statement, the original table options specified are retained. This enables you to change between `InnoDB` and `MyISAM` table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured, the active table definition (accessible through `DESCRIBE` or with `SHOW TABLE STATUS`) and the table creation string (accessible through `SHOW CREATE TABLE`) may report different values.

For `InnoDB` tables, `SHOW CREATE TABLE` and the `Create_options` column reported by `SHOW TABLE STATUS` show the actual `ROW_FORMAT` and `KEY_BLOCK_SIZE` attributes used by the table. In previous MySQL releases, the originally specified values for these attributes were reported.

### 13.1.20.2 Files Created by CREATE TABLE

For an `InnoDB` table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in an `ibd` file in the database directory. When an `InnoDB` table is created in the system tablespace, table data and indexes are stored in the `ibdata*` files that represent the system tablespace. The `innodb_file_per_table` option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The `TABLESPACE` option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the `innodb_file_per_table` setting.

For `MyISAM` tables, the storage engine creates data and index files. Thus, for each `MyISAM` table `tbl_name`, there are two disk files.
Chapter 16, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

### 13.1.20.3 CREATE TEMPORARY TABLE Syntax

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.)

*InnoDB* does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns an error if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The `innodb_file_per_table` option does not affect the creation of *InnoDB* temporary tables.

`CREATE TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database. Also, you can create a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

You cannot use `CREATE TEMPORARY TABLE ... LIKE` to create an empty table based on the definition of a table that resides in the `mysql` tablespace, *InnoDB* system tablespace (`innodb_system`), or a general tablespace. The tablespace definition for such a table includes a `TABLESPACE` attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```
Note

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13 and will be removed in a future version of MySQL.

13.1.20.4 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```sql
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

Important

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE`. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

For `CREATE TABLE ... LIKE`, the destination table preserves expression default values from the original table.

For `CREATE TABLE ... LIKE`, the destination table preserves `CHECK` constraints from the original table, except that all the constraint names are generated.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

Tables created in the `mysql` tablespace, the InnoDB system tablespace (`innodb_system`), or general tablespaces include a `TABLESPACE` attribute in the table definition, which defines the tablespace where the table resides. Due to a temporary regression, `CREATE TABLE ... LIKE` preserves the `TABLESPACE` attribute and creates the table in the defined tablespace regardless of the `innodb_file_per_table` setting. To avoid the `TABLESPACE` attribute when creating an empty table based on the definition of such a table, use this syntax instead:

```sql
CREATE TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

13.1.20.5 CREATE TABLE ... SELECT Syntax
You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT` statement. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
               -> PRIMARY KEY (a), KEY(b))
               -> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a MyISAM table with three columns, a, b, and c. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
mysql> SELECT * FROM bar;
+-----+
| m   |
| n   |
+-----+
| NULL|
+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see Comparison of the `IGNORE` Keyword and Strict SQL Mode.

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when
using **MIXED** mode. See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

**CREATE TABLE** ... **SELECT** does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the **SELECT** statement:

```sql
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For **CREATE TABLE** ... **SELECT**, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The **SELECT** part of the statement cannot assign values to generated columns in the destination table.

For **CREATE TABLE** ... **SELECT**, the destination table does preserve expression default values from the original table.

Some conversion of data types might occur. For example, the **AUTO_INCREMENT** attribute is not preserved, and **VARCHAR** columns can become **CHAR** columns. Retrained attributes are **NULL** (or **NOT NULL**) and, for those columns that have them, **CHARACTER SET**, **COLLATION**, **COMMENT**, and the **DEFAULT** clause.

When creating a table with **CREATE TABLE** ... **SELECT**, make sure to alias any function calls or expressions in the query. If you do not, the **CREATE** statement might fail or result in undesirable column names.

```sql
CREATE TABLE artists_and_works
    SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```sql
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For **CREATE TABLE** ... **SELECT**, if **IF NOT EXISTS** is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during **CREATE TABLE** ... **SELECT**.

You cannot use **FOR UPDATE** as part of the **SELECT** in a statement such as **CREATE TABLE new_table SELECT ... FROM old_table ...**. If you attempt to do so, the statement fails.

### 13.1.20.6 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and **foreign key constraints**, which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a **CREATE TABLE** or **ALTER TABLE** statement looks like this:

```sql
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name, ...)
REFERENCES tbl_name (col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

**reference_option**: **CASCADE**, **SET NULL**, **SET DEFAULT**.
index_name represents a foreign key ID. The index_name value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the CONSTRAINT symbol value is used. Otherwise, the FOREIGN KEY index_name value is used.
- If neither a CONSTRAINT symbol nor FOREIGN KEY index_name is defined, the foreign key index name is generated using the name of the referencing foreign key column.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a parent table that holds the central data values, and a child table with identical values pointing back to its parent. The FOREIGN KEY clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be TEMPORARY tables.

  In MySQL 8.0, creation of a foreign key constraint requires the REFERENCES privilege for the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of integer types must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- When foreign_key_checks is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in Section 13.1.9, “ALTER TABLE Syntax”.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. index_name, if given, is used as described previously.

- InnoDB permits a foreign key to reference any column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the first columns in the same order.

  NDB requires an explicit unique key (or primary key) on any column referenced as a foreign key.

- Index prefixes on foreign key columns are not supported. One consequence of this is that BLOB and TEXT columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- If the CONSTRAINT symbol clause is given, the symbol value, if used, must be unique in the database. A duplicate symbol will result in an error similar to: ERROR 1022 (2300): Can't write; duplicate key in table '#sql- 464_1'. If the clause is not given, or a symbol is not included following the CONSTRAINT keyword, MySQL uses the foreign key index name up to MySQL 8.0.15, and automatically generates a constraint name thereafter.

- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

This restriction does not apply for NDB tables that are partitioned by KEY or LINEAR KEY (the only user partitioning types supported by the NDB storage engine); these may have foreign key references or be the targets of such references.
• For NDB tables, **ON UPDATE CASCADE** is not supported where the reference is to the parent table’s primary key.

Additional aspects of **FOREIGN KEY** constraint usage are described under the following topics in this section:

• **Referential Actions**

• **Examples of Foreign Key Clauses**

• **Adding Foreign Keys**

• **Dropping Foreign Keys**

• **Foreign Keys and Other MySQL Statements**

• **Foreign Keys and the ANSI/ISO SQL Standard**

• **Foreign Key Metadata**

• **Foreign Key Errors**

### Referential Actions

This section describes how foreign keys help guarantee **referential integrity**.

For storage engines supporting foreign keys, MySQL rejects any **INSERT** or **UPDATE** operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an **UPDATE** or **DELETE** operation affects a key value in the parent table that has matching rows in the child table, the result depends on the **referential action** specified using **ON UPDATE** and **ON DELETE** subclauses of the **FOREIGN KEY** clause. MySQL supports five options regarding the action to be taken, listed here:

• **CASCADE**: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, do not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.

If a **FOREIGN KEY** clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an **ON UPDATE CASCADE** or **ON DELETE CASCADE** subclause defined for one **FOREIGN KEY** clause must be defined for the other in order for cascading operations to succeed. If an **ON UPDATE CASCADE** or **ON DELETE CASCADE** subclause is only defined for one **FOREIGN KEY** clause, cascading operations fail with an error.

![Note](Note)

Cascaded foreign key actions do not activate triggers.

• **SET NULL**: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to **NULL**. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, **make sure that you have not declared the columns in the child table as NOT NULL**.
CREATE TABLE Syntax

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying RESTRICT (or NO ACTION) is the same as omitting the ON DELETE or ON UPDATE clause.

- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to RESTRICT. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and NO ACTION is a deferred check. In MySQL, foreign key constraints are checked immediately, so NO ACTION is the same as RESTRICT.

- **SET DEFAULT**: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

For an ON DELETE or ON UPDATE that is not specified, the default action is always RESTRICT.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

A foreign key constraint on a stored generated column cannot use ON UPDATE CASCADE, ON DELETE SET NULL, ON UPDATE SET NULL, ON DELETE SET DEFAULT, or ON UPDATE SET DEFAULT.

A foreign key constraint cannot reference a virtual generated column.

For InnoDB restrictions related to foreign keys and generated columns, see Section 15.6.1.5, “InnoDB and FOREIGN KEY Constraints”.

**Examples of Foreign Key Clauses**

Here is a simple example that relates parent and child tables through a single-column foreign key:

```sql
CREATE TABLE parent (  
id INT NOT NULL,  
PRIMARY KEY (id)  
) ENGINE=INNODB;

CREATE TABLE child (  
id INT,  
parent_id INT,  
INDEX par_ind (parent_id),  
FOREIGN KEY (parent_id)  
REFERENCES parent(id)  
ON DELETE CASCADE  
) ENGINE=INNODB;
```

A more complex example in which a product_order table has foreign keys for two other tables. One foreign key references a two-column index in the product table. The other references a single-column index in the customer table:

```sql
CREATE TABLE product (  
category INT NOT NULL, id INT NOT NULL,  
price DECIMAL,  
PRIMARY KEY (category, id)  
) ENGINE=INNODB;

CREATE TABLE customer (  
id INT NOT NULL,  
PRIMARY KEY (id)  
) ENGINE=INNODB;

CREATE TABLE product_order (  
no INT NOT NULL AUTO_INCREMENT,
```
CREATE TABLE Syntax

| product_category INT NOT NULL, |
| product_id INT NOT NULL, |
| customer_id INT NOT NULL, |
| PRIMARY KEY, |
| INDEX (product_category, product_id), |
| INDEX (customer_id), |
| FOREIGN KEY (product_category, product_id) |
| REFERENCES product(category, id) |
| ON UPDATE CASCADE ON DELETE RESTRICT, |
| FOREIGN KEY (customer_id) |
| REFERENCES customer(id) |
| ) ENGINE=INNODB; |

Adding Foreign Keys

You can add a new foreign key constraint to an existing table by using ALTER TABLE. The syntax relating to foreign keys for this statement is shown here:

```
ALTER TABLE tbl_name
ADD [CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (col_name, ...) REFERENCES tbl_name (col_name,...) |
[ON DELETE reference_option] |
[ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using ALTER TABLE, remember to create the required indexes first.

Dropping Foreign Keys

You can also use ALTER TABLE to drop foreign keys, using the syntax shown here:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the FOREIGN KEY clause included a CONSTRAINT name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the fk_symbol value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a SHOW CREATE TABLE statement, as shown here:

```
mysql> SHOW CREATE TABLE ibtest11c\G
*************************** 1. row ***************************
Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` ( |
`A` int(11) NOT NULL auto_increment, |
`D` int(11) NOT NULL default '0', |
`B` varchar(200) NOT NULL default '', |
`C` varchar(175) default NULL, |
PRIMARY KEY  (`A`,`D`,`B`), |
KEY `B` (`B`,`C`), |
KEY `C` (`C`), |
CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`) |
REFERENCES `ibtest11a` (`A`, `D`) |
ON DELETE CASCADE ON UPDATE CASCADE, |
CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`) |
REFERENCES `ibtest11a` (`B`, `C`) |
ON DELETE CASCADE ON UPDATE CASCADE |
) ENGINE=INNODB CHARSET=utf8mb4
1 row in set (0.01 sec)
```
Adding and dropping a foreign key in the same ALTER TABLE statement is supported for ALTER TABLE ... ALGORITHM=INPLACE but is unsupported for ALTER TABLE ... ALGORITHM=COPY.

In MySQL 8.0, the server prohibits changes to foreign key columns with the potential to cause loss of referential integrity. A workaround is to use ALTER TABLE ... DROP FOREIGN KEY before changing the column definition and ALTER TABLE ... ADD FOREIGN KEY afterward.

Foreign Keys and Other MySQL Statements

Table and column identifiers in a FOREIGN KEY ... REFERENCES ... clause can be quoted within backticks (``). Alternatively, double quotation marks (") can be used if the ANSI_QUOTES SQL mode is enabled. The setting of the lower_case_table_names system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the SHOW CREATE TABLE statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the INFORMATION_SCHEMA.KEY_COLUMN_USAGE table.

You can find information about foreign keys used by InnoDB tables in the INNODB_FOREIGN and INNODB_FOREIGN_COLS tables, also in the INFORMATION_SCHEMA database.

mysqldump produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, mysqldump automatically includes a statement in the dump output to set foreign_key_checks to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting foreign_key_checks to 0 can also be useful for ignoring foreign key constraints during LOAD DATA and ALTER TABLE operations. However, even if foreign_key_checks = 0, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, ALTER TABLE cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue DROP TABLE for a table that is referenced by a FOREIGN KEY constraint, unless you do SET foreign_key_checks = 0. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an ALTER TABLE fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.
For InnoDB tables, you can obtain a detailed explanation of the most recent InnoDB foreign key error in the MySQL Server, by checking the output of `SHOW ENGINE INNODB STATUS`.

MySQL extends metadata locks, as necessary, to tables that are related by a foreign key constraint. Extending metadata locks prevents conflicting DML and DDL operations from executing concurrently on related tables. This feature also enables updates to foreign key metadata when a parent table is modified. In earlier MySQL releases, foreign key metadata, which is owned by the child table, could not be updated safely.

If a table is locked explicitly with `LOCK TABLES`, any tables related by a foreign key constraint are opened and locked implicitly. For foreign key checks, a shared read-only lock (`LOCK TABLES READ`) is taken on related tables. For cascading updates, a shared-nothing write lock (`LOCK TABLES WRITE`) is taken on related tables that are involved in the operation.

### Foreign Keys and the ANSI/ISO SQL Standard

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

Furthermore, MySQL parses but ignores "inline REFERENCES specifications" (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For storage engines that do not support foreign keys (such as MyISAM), MySQL Server parses and ignores foreign key specifications.

### Foreign Key Metadata

The `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table identifies the key columns that have constraints. Metadata specific to InnoDB foreign keys is found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables.

### Foreign Key Errors

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the most recent InnoDB foreign key error can be obtained by checking `SHOW ENGINE INNODB STATUS` output.

**Warning**

If a user has table-level privileges for all parent tables, `ER_NO_REFERENCED_ROW_2` and `ER_ROW_IS_REFERENCED_2` error messages
for foreign key operations expose information about parent tables. If a user does not have table-level privileges for all parent tables, more generic error messages are displayed instead (ER_NO_REFERENCED_ROW and ER_ROW_IS_REFERENCED).

An exception is that, for stored programs defined to execute with DEFINER privileges, the user against which privileges are assessed is the user in the program DEFINER clause, not the invoking user. If that user has table-level parent table privileges, parent table information is still displayed. In this case, it is the responsibility of the stored program creator to hide the information by including appropriate condition handlers.

13.1.20.7 CHECK Constraints

Prior to MySQL 8.0.16, CREATE TABLE permits only the following limited version of table CHECK constraint syntax, which is parsed and ignored:

```
CHECK (expr)
```

As of MySQL 8.0.16, CREATE TABLE permits the core features of table and column CHECK constraints, for all storage engines. CREATE TABLE permits the following CHECK constraint syntax, for both table constraints and column constraints:

```
[CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED]
```

The optional `symbol` specifies a name for the constraint. If omitted, MySQL generates a name from the table name, a literal `_chk_`, and an ordinal number (1, 2, 3, ...). Constraint names have a maximum length of 64 characters. They are case sensitive, but not accent sensitive.

`expr` specifies the constraint condition as a boolean expression that must evaluate to TRUE or UNKNOWN (for NULL values) for each row of the table. If the condition evaluates to FALSE, it fails and a constraint violation occurs. The effect of a violation depends on the statement being executed, as described later in this section.

The optional enforcement clause indicates whether the constraint is enforced:

- If omitted or specified as ENFORCED, the constraint is created and enforced.
- If specified as NOT ENFORCED, the constraint is created but not enforced.

A CHECK constraint is specified as either a table constraint or column constraint:

- A table constraint does not appear within a column definition and can refer to any table column or columns. Forward references are permitted to columns appearing later in the table definition.
- A column constraint appears within a column definition and can refer only to that column.

Consider this table definition:

```
CREATE TABLE t1
(
  c1 INT CHECK (c1 > 10),
  c2 INT CONSTRAINT c2_positive CHECK (c2 > 0),
  c3 INT CHECK (c3 < 100),
  CONSTRAINT c1_nonzero CHECK (c1 <> 0),
  CHECK (c1 > c3)
)
```
The definition includes table constraints and column constraints, in named and unnamed formats:

- The first constraint is a table constraint: It occurs outside any column definition, so it can (and does) refer to multiple table columns. This constraint contains forward references to columns not defined yet. No constraint name is specified, so MySQL generates a name.

- The next three constraints are column constraints: Each occurs within a column definition, and thus can refer only to the column being defined. One of the constraints is named explicitly. MySQL generates a name for each of the other two.

- The last two constraints are table constraints. One of them is named explicitly. MySQL generates a name for the other one.

As mentioned, MySQL generates a name for any CHECK constraint specified without one. To see the names generated for the preceding table definition, use SHOW CREATE TABLE:

```
mysql> SHOW CREATE TABLE t1
+-------------------+--------------------+
| Name              | Data               |
|-------------------+--------------------|
| Table: t1         | Create Table: CREATE TABLE `t1` (  `c1` int(11) DEFAULT NULL,  `c2` int(11) DEFAULT NULL,  `c3` int(11) DEFAULT NULL,  CONSTRAINT `c1_nonzero` CHECK ((`c1` <> 0)),  CONSTRAINT `c2_positive` CHECK ((`c2` > 0)),  CONSTRAINT `t1_chk_1` CHECK ((`c1` <> `c2`)),  CONSTRAINT `t1_chk_2` CHECK ((`c1` > 10)),  CONSTRAINT `t1_chk_3` CHECK ((`c3` < 100)),  CONSTRAINT `t1_chk_4` CHECK ((`c1` > `c3`)) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema (database). Consequently, CHECK constraint names must be unique per schema; no two tables in the same schema can share a CHECK constraint name. (Exception: A TEMPORARY table hides a non-TEMPORARY table of the same name, so it can have the same CHECK constraint names as well.)

Beginning generated constraint names with the table name helps ensure schema uniqueness because table names also must be unique within the schema.

CHECK condition expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Nongenerated and generated columns are permitted, except columns with the AUTO_INCREMENT attribute and columns in other tables.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: CONNECTION_ID(), CURRENT_USER(), NOW().

- Stored functions and user-defined functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.
CREATE TABLE Syntax

• Subqueries are not permitted.

Foreign key referential actions (ON UPDATE, ON DELETE) are prohibited on columns used in CHECK constraints. Likewise, CHECK constraints are prohibited on columns used in foreign key referential actions.

CHECK constraints are evaluated for INSERT, UPDATE, REPLACE, LOAD DATA, and LOAD XML statements and an error occurs if a constraint evaluates to FALSE. If an error occurs, handling of changes already applied differs for transactional and nontransactional storage engines, and also depends on whether strict SQL mode is in effect, as described in Strict SQL Mode.

CHECK constraints are evaluated for INSERT IGNORE, UPDATE IGNORE, LOAD DATA ... IGNORE, and LOAD XML ... IGNORE statements and a warning occurs if a constraint evaluates to FALSE. The insert or update for any offending row is skipped.

If the constraint expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.2, “Type Conversion in Expression Evaluation”. If type conversion fails or results in a loss of precision, an error occurs.

Note
Constraint expression evaluation uses the SQL mode in effect at evaluation time. If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

13.1.20.8 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a CREATE TABLE or ALTER TABLE statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See Section C.10.4, “Limits on Table Column Count and Row Size”.

• Columns that are part of a PRIMARY KEY are made NOT NULL even if not declared that way.

• Trailing spaces are automatically deleted from ENUM and SET member values when the table is created.

• MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.10, “Using Data Types from Other Database Engines”.

• If you include a USING clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

• If strict SQL mode is not enabled, a VARCHAR column with a length specification greater than 65535 is converted to TEXT, and a VARBINARY column with a length specification greater than 65535 is converted to BLOB. Otherwise, an error occurs in either of these cases.

• Specifying the CHARACTER SET binary attribute for a character data type causes the column to be created as the corresponding binary data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:
CREATE TABLE t
(
    c1 VARCHAR(10) CHARACTER SET binary,
    c2 TEXT CHARACTER SET binary,
    c3 ENUM('a','b','c') CHARACTER SET binary
);

The resulting table has this definition:

CREATE TABLE t
(
    c1 VARBINARY(10),
    c2 BLOB,
    c3 ENUM('a','b','c') CHARACTER SET binary
);

To see whether MySQL used a data type other than the one you specified, issue a DESCRIBE or SHOW
CREATE TABLE statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using myisampack. See
Section 16.2.3.3, “Compressed Table Characteristics”.

13.1.20.9 CREATE TABLE and Generated Columns

CREATE TABLE supports the specification of generated columns. Values of a generated column are
computed from an expression included in the column definition.

Generated columns are also supported by the NDB storage engine.

The following simple example shows a table that stores the lengths of the sides of right triangles in the
sidea and sideb columns, and computes the length of the hypotenuse in sidec (the square root of the
sums of the squares of the other sides):

CREATE TABLE triangle (
    sidea DOUBLE,
    sideb DOUBLE,
    sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);

INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);

Selecting from the table yields this result:

mysql> SELECT * FROM triangle;
+---------+---------+------------------+
<table>
<thead>
<tr>
<th>sidea</th>
<th>sideb</th>
<th>sidec</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1.4142135623730951</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>8</td>
<td>10</td>
</tr>
</tbody>
</table>
+---------+---------+------------------+

Any application that uses the triangle table has access to the hypotenuse values without having to
specify the expression that calculates them.

Generated column definitions have this syntax:

col_name data_type [GENERATED ALWAYS] AS (expr)
    [VIRTUAL | STORED] [NOT NULL | NULL]
AS (expr) indicates that the column is generated and defines the expression used to compute column values. AS may be preceded by GENERATED ALWAYS to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The VIRTUAL or STORED keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any BEFORE triggers. A virtual column takes no storage.

  InnoDB supports secondary indexes on virtual columns. See Section 13.1.20.10, “Secondary Indexes and Generated Columns”.

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is VIRTUAL if neither keyword is specified.

It is permitted to mix VIRTUAL and STORED columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be NULL, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: CONNECTION_ID(), CURRENT_USER(), NOW().

- Stored functions and user-defined functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.

- Subqueries are not permitted.

- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.

- The AUTO_INCREMENT attribute cannot be used in a generated column definition.

- An AUTO_INCREMENT column cannot be used as a base column in a generated column definition.

- If expression evaluation causes truncation or provides incorrect input to a function, the CREATE TABLE statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.2, “Type Conversion in Expression Evaluation”.
NOTE

Expression evaluation uses the SQL mode in effect at evaluation time. If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See `Table Partitioning`.

A foreign key constraint on a stored generated column cannot use `ON UPDATE CASCADE, ON DELETE SET NULL, ON UPDATE SET NULL, ON DELETE SET DEFAULT, or ON UPDATE SET DEFAULT`.

A foreign key constraint cannot reference a virtual generated column.

For `InnoDB` restrictions related to foreign keys and generated columns, see `Section 15.6.1.5, "InnoDB and FOREIGN KEY Constraints"`.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns.

For `INSERT, REPLACE, and UPDATE`, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is `DEFAULT`.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.

- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.

- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as `JSON` columns; see `Indexing a Generated Column to Provide a JSON Column Index`, for a detailed example.

For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see `Section 8.3.11, "Optimizer Use of Generated Column Indexes"`.

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:
One way to avoid writing out the expression is to create a view \textit{v1} on \textit{t1}, which simplifies applications by enabling them to select \textit{full_name} directly without using an expression:

```
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
```

A generated column also enables applications to select \textit{full_name} directly without the need to define a view:

```
CREATE TABLE t1 {
    first_name VARCHAR(10),
    last_name VARCHAR(10),
    full_name VARCHAR(255) AS (CONCAT(first_name, ' ', last_name))
};
SELECT full_name FROM t1;
```

## 13.1.20.10 Secondary Indexes and Generated Columns

\texttt{InnoDB} supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as \texttt{UNIQUE}.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a \texttt{covering index} (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during \texttt{INSERT} and \texttt{UPDATE} operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated \texttt{stored} columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for \texttt{COMPACT} and \texttt{REDUNDANT} row formats, and 3072 bytes for \texttt{DYNAMIC} and \texttt{COMPRESSED} row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

### Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, \texttt{JSON} columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:
CREATE TABLE Syntax

```
mysql> CREATE TABLE jemp (  
->  c JSON,  
->  g INT GENERATED ALWAYS AS (c->"$.id")),  
->  INDEX i (g)  
-> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES  
->  ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),  
->  ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT c->"$.name" AS name  
->  FROM jemp WHERE g > 2;
+--------+
<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barney</td>
</tr>
<tr>
<td>Betty</td>
</tr>
</tbody>
</table>
+--------+
2 rows in set (0.00 sec)
```

```
mysql> EXPLAIN SELECT c->"$.name" AS name  
->  FROM jemp WHERE g > 2\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: jemp
  partitions: NULL
  type: range
  possible_keys: i
    key: i
    key_len: 5
    ref: NULL
    rows: 2
    filtered: 100.00
    Extra: Using where
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Note
  Code: 1003
  Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

(We have wrapped the output from the last statement in this example to fit the viewing area.)

When you use EXPLAIN on a SELECT or other SQL statement containing one or more expressions that use the `->` or `->>` operator, these expressions are translated into their equivalents using JSON_EXTRACT() and (if needed) JSON_UNQUOTE() instead, as shown here in the output from SHOW WARNINGS immediately following this EXPLAIN statement:

```
mysql> EXPLAIN SELECT c->"$.name"  
->  FROM jemp WHERE g > 2 ORDER BY c->"$.name"\G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: jemp
  partitions: NULL
  type: range
  possible_keys: i
```
See the descriptions of the `->` and `-->>` operators, as well as those of the `JSON_EXTRACT()` and `JSON_UNQUOTE()` functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

**JSON columns and indirect indexing in NDB Cluster**

It is also possible to use indirect indexing of JSON columns in MySQL NDB Cluster, subject to the following conditions:

1. **NDB** handles a JSON column value internally as a `BLOB`. This means that any NDB table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.

2. The **NDB** storage engine does not support indexing of virtual columns. Since the default for generated columns is `VIRTUAL`, you must specify explicitly the generated column to which to apply the indirect index as `STORED`.

The **CREATE TABLE** statement used to create the table `jempn` shown here is a version of the `jemp` table shown previously, with modifications making it compatible with **NDB**:

```
CREATE TABLE jempn {
    a BIGINT(20) NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c JSON DEFAULT NULL,
    g INT GENERATED ALWAYS AS (c->"$.name") STORED,
    INDEX i (g)
} ENGINE=NDB;
```

We can populate this table using the following **INSERT** statement:

```
INSERT INTO jempn (a, c) VALUES
    (NULL, '{"id": "1", "name": "Fred"}'),
    (NULL, '{"id": "2", "name": "Wilma"}'),
    (NULL, '{"id": "3", "name": "Barney"}'),
    (NULL, '{"id": "4", "name": "Betty"}');
```

Now **NDB** can use index `i`, as shown here:

```
mysql> EXPLAIN SELECT c-->>"$.name" AS name
FROM jempn WHERE g > 2
G
*************************** 1. row ***************************
id: 1
```
CREATE TABLE Syntax

```
<table>
<thead>
<tr>
<th>select_type: SIMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>table: jempn</td>
</tr>
<tr>
<td>partitions: p0,p1</td>
</tr>
<tr>
<td>type: range</td>
</tr>
<tr>
<td>possible_keys: i</td>
</tr>
<tr>
<td>key: i</td>
</tr>
<tr>
<td>key_len: 5</td>
</tr>
<tr>
<td>ref: NULL</td>
</tr>
<tr>
<td>rows: 3</td>
</tr>
<tr>
<td>filtered: 100.00</td>
</tr>
<tr>
<td>Extra: Using where with pushed condition (<code>test</code>.<code>jempn</code>.'g' &gt; 2)</td>
</tr>
</tbody>
</table>
```

1 row in set, 1 warning (0.00 sec)

You should keep in mind that a stored generated column uses DataMemory, and that an index on such a column uses IndexMemory.

### 13.1.20.11 Setting NDB_TABLE Options

In MySQL NDB Cluster, the table comment in a CREATE TABLE or ALTER TABLE statement can also be used to specify an NDB_TABLE option, which consists of one or more name-value pairs, separated by commas if need be, following the string NDB_TABLE=. Complete syntax for names and values syntax is shown here:

```
COMMENT="NDB_TABLE=ndb_table_option[,nadb_table_option[,...]]"
```

**ndb_table_option:**

- NOLOGGING={1|0}
- READ_BACKUP={1|0}
- PARTITION_BALANCE={FOR_RP_BY_NODE|FOR_RA_BY_NODE|FOR_RP_BY_LDM|FOR_RA_BY_LDM|FOR_RA_BY_LDM_X_2|FOR_RA_BY_LDM_X_3|FOR_RA_BY_LDM_X_4}
- FULLY_REPLICATED={1|0}

Spaces are not permitted within the quoted string. The string is case-insensitive.

The four NDB table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

**NOLOGGING:** Using 1 corresponds to having ndb_table_no_logging enabled, but has no actual effect. Provided as a placeholder, mostly for completeness of ALTER TABLE statements.

**READ_BACKUP:** Setting this option to 1 has the same effect as though ndb_read_backup were enabled; enables reading from any replica. You can set READ_BACKUP for an existing table online, using an ALTER TABLE statement similar to one of those shown here:

```
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

For more information about the ALGORITHM option for ALTER TABLE, see Section 22.5.14, “Online Operations with ALTER TABLE in NDB Cluster”.
PARTITION_BALANCE: Provides additional control over assignment and placement of partitions. The following four schemes are supported:

1. **FOR_RP_BY_NODE**: One partition per node.
   Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM (same ID) on all nodes.

2. **FOR_RA_BY_NODE**: One partition per node group.
   Each node stores a single partition, which can be either a primary replica or a backup replica. Each partition is stored in the same LDM on all nodes.

3. **FOR_RP_BY_LDM**: One partition for each LDM on each node; the default.
   This is the same behavior as prior to MySQL NDB Cluster 7.5.2, except for a slightly different mapping of partitions to LDMs, starting with LDM 0 and placing one partition per node group, then moving on to the next LDM.
   This is the setting used if READ_BACKUP is set to 1.

4. **FOR_RA_BY_LDM**: One partition per LDM in each node group.
   These partitions can be primary or backup partitions.

5. **FOR_RA_BY_LDM_X_2**: Two partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

6. **FOR_RA_BY_LDM_X_3**: Three partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

7. **FOR_RA_BY_LDM_X_4**: Four partitions per LDM in each node group.
   These partitions can be primary or backup partitions.

**PARTITION_BALANCE** is the preferred interface for setting the number of partitions per table. Using MAX_ROWS to force the number of partitions is deprecated but continues to be supported for backward compatibility; it is subject to removal in a future release of MySQL NDB Cluster. (Bug #81759, Bug #23544301)

FULLY_REPLICATED controls whether the table is fully replicated, that is, whether each data node has a complete copy of the table. To enable full replication of the table, use FULLY_REPLICATED=1.

This setting can also be controlled using the ndb_fully_replicated system variable. Setting it to ON enables the option by default for all new NDB tables; the default is OFF. The ndb_data_node_neighbour system variable is also used for fully replicated tables, to ensure that when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a CREATE TABLE statement using such a comment when creating an NDB table is shown here:

```sql
mysql> CREATE TABLE t1 (  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  > c2 VARCHAR(100),  > c3 VARCHAR(100) )
```
CREATE TABLE Syntax

> ENGINE=NDB
> COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available from querying the MySQL Information Schema `TABLES` table, as in this example:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
  > FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>TABLE_COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>c</td>
<td>NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE</td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>
```

2 rows in set (0.00 sec)

This comment syntax is also supported with `ALTER TABLE` statements for `NDB` tables. Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have.

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can also see the value of the `PARTITION_BALANCE` option in the output of `ndb_desc`. `ndb_desc` also shows whether the `READ_BACKUP` and `FULLY_REPLICATED` options are set for the table. See the description of this program for more information.

Because the `READ_BACKUP` value was not carried over to the new comment set by the `ALTER TABLE` statement, there is no longer a way using SQL to retrieve the value previously set for it. To keep this from happening, it is suggested that you preserve any such values from the existing comment string, like this:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
  > FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>TABLE_COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>c</td>
<td>NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE</td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>
```

mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (1.56 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
  > FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>TABLE_COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>c</td>
<td>NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE</td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>
```

2 rows in set (0.01 sec)
13.1.21 CREATE TABLESPACE Syntax

CREATE [UNDO] TABLESPACE `tablespace_name`  

InnoDB and NDB:  
[ADD DATAFILE 'file_name']

InnoDB only:  
[FILE_BLOCK_SIZE = value]  
[ENCRYPTION [=] {'Y' | 'N'}]

NDB only:  
USE LOGFILE GROUP `logfile_group`  
[EXTENT_SIZE [=] `extent_size`]  
[INITIAL_SIZE [=] `initial_size`]  
[AUTOEXTEND_SIZE [=] `autoextend_size`]  
[MAX_SIZE [=] `max_size`]  
[NODEGROUP [=] `nodegroup_id`]  
[WAIT]  
[COMMENT [=] 'string']  

InnoDB and NDB:  
[ENGINE [=] `engine_name`]

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL releases, this is always an InnoDB tablespace. MySQL NDB Cluster also supports tablespaces using the NDB storage engine.

- Considerations for InnoDB
- Considerations for NDB Cluster
- Options
- Notes
- InnoDB Examples
- NDB Example

Considerations for InnoDB

CREATE TABLESPACE syntax is used to create general tablespaces or undo tablespaces. The UNDO keyword, introduced in MySQL 8.0.14, must be specified to create an undo tablespace.

A general tablespace is a shared tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can be created in a location relative to or independent of the data directory.

After creating an InnoDB general tablespace, use CREATE TABLE `tbl_name` ... TABLESPACE `tablespace_name` or ALTER TABLE `tbl_name` TABLESPACE `tablespace_name` to add tables to the tablespace. For more information, see Section 15.6.3.3, “General Tablespaces”.

Undo tablespaces contain undo logs. Undo tablespaces can be created in a chosen location by specifying a fully qualified data file path. For more information, see Section 15.6.3.4, “Undo Tablespaces”.
CREATE TABLESPACE Syntax

Considerations for NDB Cluster

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for NDB Cluster Disk Data tables (see Section 22.5.13, “NDB Cluster Disk Data Tables”). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the ALTER TABLESPACE statement (see Section 13.1.10, “ALTER TABLESPACE Syntax”).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.16, “CREATE LOGFILE GROUP Syntax”). Multiple tablespaces may use the same log file group for UNDO logging.

When setting EXTENT_SIZE or INITIAL_SIZE, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

INITIAL_SIZE and EXTENT_SIZE are subject to rounding as follows:

- EXTENT_SIZE is rounded up to the nearest whole multiple of 32K.
- INITIAL_SIZE is rounded down to the nearest whole multiple of 32K; this result is rounded up to the nearest whole multiple of EXTENT_SIZE (after any rounding).

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating INFORMATION_SCHEMA.FILES column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When CREATE TABLESPACE is used with ENGINE [=] NDB, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. (See the example later in this section.)

(See Section 25.11, “The INFORMATION_SCHEMA FILES Table”.)

Options

- ADD DATAFILE: Defines the name of a tablespace data file. The ADD DATAFILE clause is required when creating undo tablespaces. Otherwise, it is optional as of MySQL 8.0.14.

An InnoDB tablespace supports only a single data file, whose name must include a .ibd extension. An NDB Cluster tablespace supports multiple data files which can have any legal file names; more data files can be added to an NDB Cluster tablespace following its creation by using an ALTER TABLESPACE statement.

To place a general tablespace data file in a location outside of the data directory, include a fully qualified path or a path relative to the data directory. Only a fully qualified path is permitted for undo tablespaces. If you do not specify a path, a general tablespace is created in the data directory. An undo tablespace created without specifying a path is created in the directory defined by the innodb_undo_directory...
CREATE TABLESPACE Syntax

variable. If the `innodb_undo_directory` variable is undefined, undo tablespaces are created in the
data directory.

Creating a general tablespace in a subdirectory under the data directory is not supported to avoid
conflicts with implicitly created file-per-table tablespaces. When creating a general tablespace or undo
tablespace outside of the data directory, the directory must exist and must be known to InnoDB prior to
creating the tablespace. To make a directory known to InnoDB, add it to the `innodb_directories`
value or to one of the variables whose values are appended to the `innodb_directories` value.
`innodb_directories` is a read-only variable. Configuring it requires restarting the server.

The `file_name`, including any specified path, must be quoted with single or double quotations marks.
File names (not counting the file extension) and directory names must be at least one byte in length.
Zero length file names and directory names are not supported.

If the `ADD DATAFILE` clause is not specified when creating a tablespace, a tablespace data file with a
unique file name is created implicitly. The unique file name is a 128 bit UUID formatted into five groups
of hexadecimal numbers separated by dashes (`aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee`). A
file extension is added if required by the storage engine. An `.ibd` file extension is added for InnoDB
general tablespace data files. In a replication environment, the data file name created on the master is
not the same as the data file name created on the slave.

- **FILE_BLOCK_SIZE**: This option—which is specific to InnoDB general tablespaces, and is
  ignored by NDB—defines the block size for the tablespace data file. Values can be specified in
  bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If
  you do not specify this option, `FILE_BLOCK_SIZE` defaults to the `innodb_page_size` value.
  `FILE_BLOCK_SIZE` is required when you intend to use the tablespace for storing compressed InnoDB
tables (`ROW_FORMAT=COMPRESSED`). In this case, you must define the tablespace `FILE_BLOCK_SIZE`
  when creating the tablespace.

If `FILE_BLOCK_SIZE` is equal the `innodb_page_size` value, the tablespace can contain only
tables having an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC`). Tables with a
`COMPRESSED` row format have a different physical page size than uncompressed tables. Therefore,
compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, `FILE_BLOCK_SIZE` must be specified, and the
`FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size`
value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to
`FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K`, and `FILE_BLOCK_SIZE=8K`,
the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see Section 15.6.3.3, “General
Tablespaces”.

- **USE LOGFILE GROUP**: Required for NDB, this is the name of a log file group previously created using
  CREATE LOGFILE GROUP. Not supported for InnoDB, where it fails with an error.

- **EXTENT_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an
  error. `EXTENT_SIZE` sets the size, in bytes, of the extents used by any files belonging to the tablespace.
The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the
practical maximum size depends on a number of factors. In most cases, changing the extent size does
not have any measurable effect on performance, and the default value is recommended for all but the
most unusual situations.

An extent is a unit of disk space allocation. One extent is filled with as much data as that extent can
contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file;
however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single
data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a
given partition, it cannot be used to store data from a different partition; an extent cannot store data
CREATE TABLESPACE Syntax

from more than one partition. This means, for example that a tablespace having a single datafile whose
INITIAL_SIZE (described in the following item) is 256 MB and whose EXTENT_SIZE is 128M has just
two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the
INFORMATION_SCHEMA.FILES table, and so derive an estimate for how much space remains free in
the file. For further discussion and examples, see Section 25.11, “The INFORMATION_SCHEMA FILES
Table”.

• INITIAL_SIZE: This option is specific to NDB, and is not supported by InnoDB, where it fails with an
error.

The INITIAL_SIZE parameter sets the total size in bytes of the data file that was specific using ADD
DATATFILE. Once this file has been created, its size cannot be changed; however, you can add more
data files to the tablespace using ALTER TABLESPACE ... ADD DATATFILE.

INITIAL_SIZE is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB).

• AUTOEXTEND_SIZE: Currently ignored by MySQL; reserved for possible future use. Has no effect in any
release of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

• MAX_SIZE: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

• NODEGROUP: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

• WAIT: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

• COMMENT: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 8.0 or MySQL NDB Cluster 8.0, regardless of the storage engine used.

• The ENCRYPTION option is used to enable or disable page-level data encryption for an InnoDB general
tablespace. Option values are not case-sensitive. Encryption support for general tablespaces was
introduced in MySQL 8.0.13. A keyring plugin must be installed and configured to use the ENCRYPTION
option.

When a general tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a
table created in an encrypted tablespace is encrypted.

For more information, see Section 15.6.3.9, “Tablespace Encryption”

• ENGINE: Defines the storage engine which uses the tablespace, where engine_name is the name
of the storage engine. Currently, only the InnoDB storage engine is supported by standard MySQL
8.0 releases. MySQL NDB Cluster supports both NDB and InnoDB tablespaces. The value of the
default_storage_engine system variable is used for ENGINE if the option is not specified.

Notes

• For the rules covering the naming of MySQL tablespaces, see Section 9.2, “Schema Object Names”. In
addition to these rules, the slash character (“/”) is not permitted, nor can you use names beginning with
innodb_, as this prefix is reserved for system use.

• Creation of temporary general tablespaces is not supported.
• General tablespaces do not support temporary tables.

• The TABLESPACE option may be used with CREATE TABLE or ALTER TABLE to assign an InnoDB table partition or subpartition to a file-per-table tablespace. All partitions must belong to the same storage engine. Assigning table partitions to shared InnoDB tablespaces is not supported. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

• General tablespaces support the addition of tables of any row format using CREATE TABLE ... TABLESPACE. innodb_file_per_table does not need to be enabled.

• innodb_strict_mode is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of innodb_strict_mode. If CREATE TABLESPACE parameters are incorrect or incompatible, the operation fails regardless of the innodb_strict_mode setting. When a table is added to a general tablesapce using CREATE TABLE ... TABLESPACE or ALTER TABLE ... TABLESPACE, innodb_strict_mode is ignored but the statement is evaluated as if innodb_strict_mode is enabled.

• Use DROP TABLESPACE to remove a tablesapce. All tables must be dropped from a tablesapce using DROP TABLE prior to dropping the tablespace. Before dropping an NDB Cluster tablesapce you must also remove all its data files using one or more ALTER TABLESPACE ... DROP DATATFILE statements. See Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

• All parts of an InnoDB table added to an InnoDB general tablesapce reside in the general tablesapce, including indexes and BLOB pages.

For an NDB table assigned to a tablesapce, only those columns which are not indexed are stored on disk, and actually use the tablesapce data files. Indexes and indexed columns for all NDB tables are always kept in memory.

• Similar to the system tablesapce, truncating or dropping tables stored in a general tablesapce creates free space internally in the general tablesapce .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablesspaces.

• A general tablesapce is not associated with any database or schema.

• ALTER TABLE ... DISCARD TABLESPACE and ALTER TABLE ...IMPORT TABLESPACE are not supported for tables that belong to a general tablesapce.

• The server uses tablesapce-level metadata locking for DDL that references general tablesapces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablesapces.

• A generated or existing tablesapce cannot be changed to a general tablesapce.

• There is no conflict between general tablesapce names and file-per-table tablesapce names. The “/” character, which is present in file-per-table tablesapce names, is not permitted in general tablesapce names.

• mysqldump and mysqlpump do not dump InnoDB CREATE TABLESPACE statements.

InnoDB Examples

This example demonstrates creating a general tablesapce and adding three uncompressed tables of different row formats.

    mysql> CREATE TABLESPACE `ts1` ADD DATAFILE `ts1.ibd` ENGINE=INNODB;
CREATE TABLESPACE Syntax

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default \texttt{innodb_page_size} value of 16K. The \texttt{FILE_BLOCK_SIZE} of 8192 requires that the compressed table have a \texttt{KEY_BLOCK_SIZE} of 8.

mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;

This example demonstrates creating a general tablespace without specifying the \texttt{ADD DATAFILE} clause, which is optional as of MySQL 8.0.14.

mysql> CREATE TABLESPACE `ts3` ENGINE=INNODB;

This example demonstrates creating an undo tablespace.

mysql> CREATE UNDO TABLESPACE undo_003 ADD DATAFILE 'undo_003.ibu';

\section*{NDB Example}

Suppose that you wish to create an NDB Cluster Disk Data tablespace named \texttt{myts} using a datafile named \texttt{mydata-1.dat}. An NDB tablespace always requires the use of a log file group consisting of one or more undo log files. For this example, we first create a log file group named \texttt{mylg} that contains one undo long file named \texttt{myundo-1.dat}, using the \texttt{CREATE LOGFILE GROUP} statement shown here:

mysql> CREATE LOGFILE GROUP mylg
    -> ADD UNDOFILE 'myundo-1.dat'
    -> ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)

Now you can create the tablespace previously described using the following statement:

mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
Query OK, 0 rows affected (2.98 sec)

You can now create a Disk Data table using a \texttt{CREATE TABLE} statement with the \texttt{TABLESPACE} and \texttt{STORAGE DISK} options, similar to what is shown here:

mysql> CREATE TABLE mytable (  
    -> id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> lname VARCHAR(50) NOT NULL,
    -> fname VARCHAR(50) NOT NULL,
    -> dob DATE NOT NULL,
    -> joined DATE NOT NULL,
    -> INDEX(last_name, first_name)
    -> )
    -> TABLESPACE myts STORAGE DISK
    -> ENGINE=NDB;
It is important to note that only the `dob` and `joined` columns from `mytable` are actually stored on disk, due to the fact that the `id`, `lname`, and `fname` columns are all indexed.

As mentioned previously, when `CREATE TABLESPACE` is used with `ENGINE [=] NDB`, a tablespace and associated data file are created on each NDB Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table, as shown here:

```sql
mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'myts';
```

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_type</th>
<th>logfile_group_name</th>
<th>status</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=5</td>
</tr>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=6</td>
</tr>
<tr>
<td>NULL</td>
<td>TABLESPACE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

3 rows in set (0.01 sec)

For additional information and examples, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

### 13.1.22 CREATE TRIGGER Syntax

```sql
CREATE
    [DEFINER = { user | CURRENT_USER }]
TRIGGER trigger_name
trigger_time trigger_event
ON tbl_name FOR EACH ROW
[trigger_order]
trigger_body
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see Section 24.3.1, “Trigger Syntax and Examples”.

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. The statement might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as described in Section 24.7, “Binary Logging of Stored Programs”.

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.
**trigger_time** is the trigger action time. It can be **BEFORE** or **AFTER** to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use **BEFORE** triggers to convert values inappropriate for the column type to valid values.

**trigger_event** indicates the kind of operation that activates the trigger. These **trigger_event** values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table; for example, through **INSERT**, **LOAD DATA**, and **REPLACE** statements.

- **UPDATE**: The trigger activates whenever a row is modified; for example, through **UPDATE** statements.

- **DELETE**: The trigger activates whenever a row is deleted from the table; for example, through **DELETE** and **REPLACE** statements. **DROP TABLE** and **TRUNCATE TABLE** statements on the table do not activate this trigger, because they do not use **DELETE**. Dropping a partition does not activate **DELETE** triggers, either.

The **trigger_event** does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an **INSERT** trigger activates not only for **INSERT** statements but also **LOAD DATA** statements because both statements insert rows into a table.

A potentially confusing example of this is the **INSERT INTO ... ON DUPLICATE KEY UPDATE ...** syntax: a **BEFORE INSERT** trigger activates for every row, followed by either an **AFTER INSERT** trigger or both the **BEFORE UPDATE** and **AFTER UPDATE** triggers, depending on whether there was a duplicate key for the row.

---

**Note**

Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two **BEFORE UPDATE** triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a **trigger_order** clause that indicates **FOLLOWS** or **PRECEDES** and the name of an existing trigger that also has the same trigger event and action time. With **FOLLOWS**, the new trigger activates after the existing trigger. With **PRECEDES**, the new trigger activates before the existing trigger.

**trigger_body** is the statement to execute when the trigger activates. To execute multiple statements, use the **BEGIN ... END** compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See Section 13.6.1, “**BEGIN ... END Compound-Statement Syntax**”. Some statements are not permitted in triggers; see Section C.1, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases **OLD** and **NEW.OLD.col_name** refers to a column of an existing row before it is updated or deleted. **NEW.col_name** refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use **NEW.col_name** or use **OLD.col_name** to refer to generated columns. For information about generated columns, see Section 13.1.20.9, “**CREATE TABLE and Generated Columns**”.

MySQL stores the **sql_mode** system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, **regardless of the current server SQL mode when the trigger begins executing**.
The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `user_name`@`host_name`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `TRIGGER` privilege for the subject table.
  - The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
  - Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see Section 24.6, “Access Control for Stored Programs and Views”.

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”.

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in `LOCK TABLES` and `Triggers`.

For additional discussion of trigger use, see Section 24.3.1, “Trigger Syntax and Examples”.

### 13.1.23 CREATE VIEW Syntax

```
CREATE [OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = {'user' | CURRENT_USER}]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
```
CREATE VIEW Syntax

```
AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see Section C.5, “Restrictions on Views”.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. `CREATE VIEW` might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:
CREATE VIEW Syntax

CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
</tbody>
</table>
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

ORDER BY is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own ORDER BY.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a LIMIT clause, and you select from the view using a statement that has its own LIMIT clause, it is undefined which limit applies. This same principle applies to options such as ALL, DISTINCT, or SQL_SMALL_RESULT that follow the `SELECT` keyword, and to clauses such as INTO, FOR UPDATE, FOR SHARE, LOCK IN SHARE MODE, and PROCEDURE.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:
CREATE VIEW Syntax

The **DEFINER** and **SQL SECURITY** clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid **SQL SECURITY** characteristic values are **DEFINER** (the default) and **INVOKER**. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a **user** value is given for the **DEFINER** clause, it should be a MySQL account specified as '\user_name'@'host_name', **CURRENT_USER**, or **CURRENT_USER()**. The default **DEFINER** value is the user who executes the **CREATE VIEW** statement. This is the same as specifying **DEFINER = CURRENT_USER** explicitly.

If the **DEFINER** clause is present, these rules determine the valid **DEFINER** user values:

- If you do not have the **SET_USER_ID** or **SUPER** privilege, the only valid **user** value is your own account, either specified literally or by using **CURRENT_USER**. You cannot set the definer to some other account.
- If you have the **SET_USER_ID** or **SUPER** privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a view with a nonexistent **DEFINER** account, an error occurs when the view is referenced if the **SQL SECURITY** value is **DEFINER** but the definer account does not exist.

For more information about view security, see Section 24.6, “Access Control for Stored Programs and Views”.

Within a view definition, **CURRENT_USER** returns the view's **DEFINER** value by default. For views defined with the **SQL SECURITY INVOKER** characteristic, **CURRENT_USER** returns the account for the view's invoker. For information about user auditing within views, see Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”.

Within a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, **CURRENT_USER** returns the routine's **DEFINER** value. This also affects a view defined within such a routine, if the view definition contains a **DEFINER** value of **CURRENT_USER**.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the **SELECT** privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it (**SELECT** to select from it, **INSERT** to insert into it, and so forth.)
CREATE VIEW Syntax

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view **DEFINER** account or invoker, depending on whether the **SQL SECURITY** characteristic is **DEFINER** or **INVOKER**, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function **SQL SECURITY** characteristic is **DEFINER** or **INVOKER**. If the security characteristic is **DEFINER**, the function runs with the privileges of the **DEFINER** account. If the characteristic is **INVOKER**, the function runs with the privileges determined by the view's **SQL SECURITY** characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function \( f() \):

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that \( f() \) contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within \( f() \) need to be checked when \( f() \) executes. This might mean that privileges are needed for \( p1() \) or \( p2() \), depending on the execution path within \( f() \). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the **SQL SECURITY** values of the view \( v \) and the function \( f() \).

The **DEFINER** and **SQL SECURITY** clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for **SQL SECURITY DEFINER**. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, **SELECT**) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The **DEFINER** clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default **DEFINER** value is the account of the view creator.

The optional **ALGORITHM** clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. **ALGORITHM** takes three values: **MERGE**, **TEMPTABLE**, or **UNDEFINED**. For more information, see Section 24.5.2, “View Processing Algorithms”, as well as Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

Some views are updatable. That is, you can use them in statements such as **UPDATE**, **DELETE**, or **INSERT** to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 13.1.20.9, “CREATE TABLE and Generated Columns”.

The **WITH CHECK OPTION** clause can be given for an updatable view to prevent inserts or updates to rows except those for which the **WHERE** clause in the **select_statement** is true.

In a **WITH CHECK OPTION** clause for an updatable view, the **LOCAL** and **CASCADED** keywords determine the scope of check testing when the view is defined in terms of another view. The **LOCAL** keyword restricts
the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED.

For more information about updatable views and the WITH CHECK OPTION clause, see Section 24.5.3, “Updatable and Insertable Views”, and Section 24.5.4, “The View WITH CHECK OPTION Clause”.

13.1.24 DROP DATABASE Syntax

DROP {DATABASE | SCHEMA} [IF EXISTS] db_name

DROP DATABASE drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. DROP SCHEMA is a synonym for DROP DATABASE.

Important

When a database is dropped, privileges granted specifically for the database are not automatically dropped. They must be dropped manually. See Section 13.7.1.6, “GRANT Syntax”.

IF EXISTS is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the DATABASE() function returns NULL).

If you use DROP DATABASE on a symbolically linked database, both the link and the original database are deleted.

DROP DATABASE returns the number of tables that were removed.

The DROP DATABASE statement removes from the given database directory those files and directories that MySQL itself may create during normal operation. This includes all files with the extensions shown in the following list:

- .BAK
- .DAT
- .HSH
- .MRG
- .MYD
- .MYI
- .cfg
- .db
- .ibd
- .ndb

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the DROP DATABASE statement again.
Dropping a database does not remove any \texttt{TEMPORARY} tables that were created in that database. \texttt{TEMPORARY} tables are automatically removed when the session that created them ends. See Section 13.1.20.3, “CREATE TEMPORARY TABLE Syntax”.

You can also drop databases with \texttt{mysqladmin}. See Section 4.5.2, “\texttt{mysqladmin} — Client for Administering a MySQL Server”.

13.1.25 DROP EVENT Syntax

\begin{verbatim}
DROP EVENT [IF EXISTS] event_name
\end{verbatim}

This statement drops the event named \textit{event_name}. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error \texttt{ERROR 1517 (HY000): Unknown event 'event_name'} results. You can override this and cause the statement to generate a warning for nonexistent events instead using \texttt{IF EXISTS}.

This statement requires the \texttt{EVENT} privilege for the schema to which the event to be dropped belongs.

13.1.26 DROP FUNCTION Syntax

The \texttt{DROP FUNCTION} statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see Section 13.1.29, “DROP PROCEDURE and DROP FUNCTION Syntax”.

- For information about dropping user-defined functions, see Section 13.7.4.2, “DROP FUNCTION Syntax”.

13.1.27 DROP INDEX Syntax

\begin{verbatim}
DROP INDEX index_name ON tbl_name
   [algorithm_option | lock_option] ...
\end{verbatim}

algorithm_option:
   \texttt{ALGORITHM [\texttt{\texttt{=}}} \{\texttt{DEFAULT|INPLACE|COPY}\}

lock_option:
   \texttt{LOCK [\texttt{\texttt{=}}} \{\texttt{DEFAULT|NONE|SHARED|EXCLUSIVE}\}

\texttt{DROP INDEX} drops the index named \textit{index_name} from the table \textit{tbl_name}. This statement is mapped to an \texttt{ALTER TABLE} statement to drop the index. See Section 13.1.9, “\texttt{ALTER TABLE Syntax}”.

To drop a primary key, the index name is always \texttt{PRIMARY}, which must be specified as a quoted identifier because \texttt{PRIMARY} is a reserved word:

\begin{verbatim}
DROP INDEX `PRIMARY` ON t;
\end{verbatim}

Indexes on variable-width columns of \texttt{NDB} tables are dropped online; that is, without any table copying. The table is not locked against access from other \texttt{NDB Cluster API} nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.
ALGORITHM and LOCK clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the ALTER TABLE statement. For more information, see Section 13.1.9, “ALTER TABLE Syntax”.

MySQL NDB Cluster supports online operations using the same ALGORITHM=INPLACE syntax supported in the standard MySQL Server. See Section 22.5.14, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

### 13.1.28 DROP LOGFILE GROUP Syntax

```
DROP LOGFILE GROUP logfile_group
    ENGINE [=] engine_name
```

This statement drops the log file group named `logfile_group`. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.16, “CREATE LOGFILE GROUP Syntax”.)

**Important**

Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.

The required ENGINE clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for `engine_name` are NDB and NDBCLUSTER.

DROP LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 22.5.13, “NDB Cluster Disk Data Tables”.

### 13.1.29 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the ALTER ROUTINE privilege for the routine. (If the automatic_sp_privileges system variable is enabled, that privilege and EXECUTE are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 24.2.2, “Stored Routines and MySQL Privileges”.)

The IF EXISTS clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with SHOW WARNINGS.

DROP FUNCTION is also used to drop user-defined functions (see Section 13.7.4.2, “DROP FUNCTION Syntax”).

### 13.1.30 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named `server_name`. The corresponding row in the mysql.servers table is deleted. This statement requires the SUPER privilege.

Dropping a server for a table does not affect any FEDERATED tables that used this connection information when they were created. See Section 13.1.18, “CREATE SERVER Syntax”. 
**DROP SPATIAL REFERENCE SYSTEM Syntax**

**DROP SERVER** causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

**DROP SERVER** is not written to the binary log, regardless of the logging format that is in use.

### 13.1.31 DROP SPATIAL REFERENCE SYSTEM Syntax

```
DROP SPATIAL REFERENCE SYSTEM
   [IF EXISTS]
     srid
srid: 32-bit unsigned integer
```

This statement removes a spatial reference system (SRS) definition from the data dictionary. It requires the **SUPER** privilege.

Example:

```
DROP SPATIAL REFERENCE SYSTEM 4120;
```

If no SRS definition with the SRID value exists, an error occurs unless **IF EXISTS** is specified. In that case, a warning occurs rather than an error.

If the SRID value is used by some column in an existing table, an error occurs. For example:

```
mysql> DROP SPATIAL REFERENCE SYSTEM 4326;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at least one column depending on it.
```

To identify which column or columns use the SRID, use this query:

```
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with **DROP SPATIAL REFERENCE SYSTEM**.

- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the European Petroleum Survey Group.

- Users should not drop SRSs with SRIDs in the reserved ranges. If system-installed SRSs are dropped, the SRS definitions may be recreated for MySQL upgrades.

### 13.1.32 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
     tbl_name [, tbl_name] ... [RESTRICT | CASCADE]
```

**DROP TABLE** removes one or more tables. You must have the **DROP** privilege for each table.

*Be careful* with this statement! It removes the table definition and all table data. For a partitioned table, it permanently removes the table definition, all its partitions, and all data stored in those partitions. It also removes partition definitions associated with the dropped table.
Dropping a table also drops any triggers for the table.

DROP TABLE causes an implicit commit, except when used with the TEMPORARY keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

Important
When a table is dropped, privileges granted specifically for the table are not automatically dropped. They must be dropped manually. See Section 13.7.1.6, “GRANT Syntax”.

If any tables named in the argument list do not exist, the statement fails with an error indicating by name which nonexisting tables it was unable to drop, and no changes are made.

Use IF EXISTS to prevent an error from occurring for tables that do not exist. Instead of an error, a NOTE is generated for each nonexistent table; these notes can be displayed with SHOW WARNINGS. See Section 13.7.6.40, “SHOW WARNINGS Syntax”.

IF EXISTS can also be useful for dropping tables in unusual circumstances under which there is an entry in the data dictionary but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before removal of the data dictionary entry.)

The TEMPORARY keyword has the following effects:

• The statement drops only TEMPORARY tables.

• The statement does not cause an implicit commit.

• No access rights are checked. A TEMPORARY table is visible only with the session that created it, so no check is necessary.

Using TEMPORARY is a good way to ensure that you do not accidentally drop a non-TEMPORARY table.

The RESTRICT and CASCADE keywords do nothing. They are permitted to make porting easier from other database systems.

DROP TABLE is not supported with all innodb_force_recovery settings. See Section 15.20.2, “Forcing InnoDB Recovery”.

13.1.33 DROP TABLESPACE Syntax

DROP [UNDO] TABLESPACE tablespace_name
   [ENGINE [-] engine_name]

This statement drops a tablespace that was previously created using CREATE TABLESPACE. It is supported by the NDB and InnoDB storage engines.

The UNDO keyword, introduced in MySQL 8.0.14, must be specified to drop an undo tablespace. Only undo tablespaces created using CREATE UNDO TABLESPACE syntax can be dropped. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

ENGINE sets the storage engine that uses the tablespace, where engine_name is the name of the storage engine. Currently, the values InnoDB and NDB are supported. If not set, the value of default_storage_engine is used. If it is not the same as the storage engine used to create the tablespace, the DROP TABLESPACE statement fails.
**DROP TABLESPACE Syntax**

$tablespace_name$ is a case-sensitive identifier in MySQL.

For an InnoDB general tablespace, all tables must be dropped from the tablespace prior to a **DROP TABLESPACE** operation. If the tablespace is not empty, **DROP TABLESPACE** returns an error.

An NDB tablespace to be dropped must not contain any data files; in other words, before you can drop an NDB tablespace, you must first drop each of its data files using **ALTER TABLESPACE ... DROP DATAFILE**.

**Notes**

- A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using **DROP TABLESPACE $tablespace_name$**.

- A **DROP DATABASE** operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using **DROP TABLESPACE $tablespace_name$**.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

**InnoDB Examples**

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace $ts1$ is created with a single table. Before dropping the tablespace, the table must be dropped.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts10 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

This example demonstrates dropping an undo tablespace. An undo tablespace must be in an empty state before it can be dropped. For more information, see Section 15.6.3.4, “Undo Tablespaces”.

```sql
mysql> DROP UNDO TABLESPACE undo_003;
```

**NDB Example**

This example shows how to drop an NDB tablespace $myts$ having a data file named $mydata-1.dat$ after first creating the tablespace, and assumes the existence of a log file group named mylg (see Section 13.1.16, “CREATE LOGFILE GROUP Syntax”).

```sql
mysql> CREATE TABLESPACE myts
    
    -> ADD DATAFILE 'mydata-1.dat'
    
    -> USE LOGFILE GROUP mylg
    
    -> ENGINE=NDB;
    
mysql> ALTER TABLESPACE myts
    
    -> DROP DATAFILE 'mydata-1.dat'
    
You must remove all data files from the tablespace using **ALTER TABLESPACE**, as shown here, before it can be dropped:

```sql
mysql> ALTER TABLESPACE myts
    
    -> DROP DATAFILE 'mydata-1.dat'
```
13.1.34 DROP TRIGGER Syntax

DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. DROP TRIGGER requires the TRIGGER privilege for the table associated with the trigger.

Use IF EXISTS to prevent an error from occurring for a trigger that does not exist. A NOTE is generated for a nonexistent trigger when using IF EXISTS. See Section 13.7.6.40, “SHOW WARNINGS Syntax”.

Triggers for a table are also dropped if you drop the table.

13.1.35 DROP VIEW Syntax

DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]

DROP VIEW removes one or more views. You must have the DROP privilege for each view.

If any views named in the argument list do not exist, the statement fails with an error indicating by name which nonexisting views it was unable to drop, and no changes are made.

Note

In MySQL 5.7 and earlier, DROP VIEW returns an error if any views named in the argument list do not exist, but also drops all views in the list that do exist. Due to the change in behavior in MySQL 8.0, a partially completed DROP VIEW operation on a MySQL 5.7 master fails when replicated on a MySQL 8.0 slave. To avoid this failure scenario, use IF EXISTS syntax in DROP VIEW statements to prevent an error from occurring for views that do not exist. For more information, see Section 13.1.1, "Atomic Data Definition Statement Support".

The IF EXISTS clause prevents an error from occurring for views that don't exist. When this clause is given, a NOTE is generated for each nonexistent view. See Section 13.7.6.40, "SHOW WARNINGS Syntax".

RESTRICT and CASCADE, if given, are parsed and ignored.

13.1.36 RENAME TABLE Syntax

RENAME TABLE
tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...

RENAME TABLE renames one or more tables. You must have ALTER and DROP privileges for the original table, and CREATE and INSERT privileges for the new table.

For example, to rename a table named old_table to to new_table, use this statement:
RENAME TABLE old_table TO new_table;

That statement is equivalent to the following ALTER TABLE statement:

ALTER TABLE old_table RENAME new_table;

RENAME TABLE, unlike ALTER TABLE, can rename multiple tables within a single statement:

RENAME TABLE old_table1 TO new_table1,
old_table2 TO new_table2,
old_table3 TO new_table3;

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name tmp_table does not already exist):

RENAME TABLE old_table TO tmp_table,
new_table TO old_table,
tmp_table TO new_table;

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, “Metadata Locking”.

As of MySQL 8.0.13, you can rename tables locked with a LOCK TABLES statement, provided that they are locked with a WRITE lock or are the product of renaming WRITE-locked tables from earlier steps in a multiple-table rename operation. For example, this is permitted:

LOCK TABLE old_table1 WRITE;
RENAME TABLE old_table1 TO new_table1,
new_table1 TO new_table2;

This is not permitted:

LOCK TABLE old_table1 READ;
RENAME TABLE old_table1 TO new_table1,
new_table1 TO new_table2;

Prior to MySQL 8.0.13, to execute RENAME TABLE, there must be no tables locked with LOCK TABLES.

With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a RENAME TABLE, the statement fails and no changes are made.

You can use RENAME TABLE to move a table from one database to another:

RENAME TABLE current_db.tbl_name TO other_db.tbl_name;

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like RENAME TABLE, ALTER TABLE ... RENAME can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database
located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA) error.

To rename TEMPORARY tables, RENAME TABLE does not work. Use ALTER TABLE instead.

RENAME TABLE works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated and user-defined CHECK constraint names that begin with the string "tbl_name_chk_" to reflect the new table name. MySQL interprets CHECK constraint names that begin with the string "tbl_name_chk_" as internally generated names. Example:

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (   `i1` int(11) DEFAULT NULL,   `i2` int(11) DEFAULT NULL,   CONSTRAINT `t1_chk_1` CHECK ((`i1` > 0)),   CONSTRAINT `t1_chk_2` CHECK ((`i2` < 0)) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.02 sec)
mysql> RENAME TABLE t1 TO t3;
Query OK, 0 rows affected (0.03 sec)
mysql> SHOW CREATE TABLE t3\G
*************************** 1. row ***************************
Table: t3
Create Table: CREATE TABLE `t3` (   `i1` int(11) DEFAULT NULL,   `i2` int(11) DEFAULT NULL,   CONSTRAINT `t3_chk_1` CHECK ((`i1` > 0)),   CONSTRAINT `t3_chk_2` CHECK ((`i2` < 0)) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.01 sec)
```

13.1.37 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

TRUNCATE TABLE empties a table completely. It requires the DROP privilege. Logically, TRUNCATE TABLE is similar to a DELETE statement that deletes all rows, or a sequence of DROP TABLE and CREATE TABLE statements.
To achieve high performance, `TRUNCATE TABLE` bypasses the DML method of deleting data. Thus, it does not cause `ON DELETE` triggers to fire, it cannot be performed for InnoDB tables with parent-child foreign key relationships, and it cannot be rolled back like a DML operation. However, `TRUNCATE TABLE` operations on tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. For more information, see Section 13.1.1, “Atomic Data Definition Statement Support”.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, “Statements That Cause an Implicit Commit”.
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an InnoDB table or NDB table if there are any FOREIGN KEY constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table definition is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions are unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.
- Truncating a corrupted InnoDB table is supported.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using InnoDB and other transactional storage engines where the transaction isolation level does not permit statement-based logging (READ COMMITTED or READ UNCOMMITTED), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using InnoDB in the manner described previously.

In MySQL 5.7 and earlier, on a system with a large buffer pool and `innodb_adaptive_hash_index` enabled, a `TRUNCATE TABLE` operation could cause a temporary drop in system performance due to an LRU scan that occurred when removing the table's adaptive hash index entries (Bug #68184). The remapping of `TRUNCATE TABLE` to `DROP TABLE` and `CREATE TABLE` in MySQL 8.0 avoids the problematic LRU scan.

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See Section 26.12.16, “Performance Schema Summary Tables”.
13.2 Data Manipulation Statements

13.2.1 CALL Syntax

CALL sp_name([parameter[, ...]])
CALL sp_name()  

The CALL statement invokes a stored procedure that was defined previously with CREATE PROCEDURE. Stored procedures that take no arguments can be invoked without parentheses. That is, CALL p() and CALL p are equivalent.

CALL can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the ROW_COUNT() function; from the C API, call the mysql_affected_rows() function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

To get back a value from a procedure using an OUT or INOUT parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.) For an INOUT parameter, initialize its value before passing it to the procedure. The following procedure has an OUT parameter that the procedure sets to the current server version, and an INOUT value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the INOUT parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+--------------------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.0.3-rc-debug-log</td>
<td>11</td>
</tr>
</tbody>
</table>
+--------------------+------------+
```

In prepared CALL statements used with PREPARE and EXECUTE, placeholders can be used for IN parameters, OUT, and INOUT parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+--------------------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.0.3-rc-debug-log</td>
<td>11</td>
</tr>
</tbody>
</table>
+--------------------+------------+
```
To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 28.7.23, “C API Multiple Statement Execution Support”.

C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see Section 28.7.25, “C API Prepared CALL Statement Support”. Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.3, “Caching of Prepared Statements and Stored Programs”.

### 13.2.2 DELETE Syntax

`DELETE` is a DML statement that removes rows from a table.

A `DELETE` statement can start with a `WITH` clause to define common table expressions accessible within the `DELETE`. See Section 13.2.13, “WITH Syntax (Common Table Expressions)”.

#### Single-Table Syntax

```sql
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name [[AS] tbl_alias]
    [PARTITION (partition_name [, partition_name] ...)]
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

The `DELETE` statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in Section 12.15, “Information Functions”.

#### Main Clauses

The conditions in the optional `WHERE` clause identify which rows to delete. With no `WHERE` clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.10, “SELECT Syntax”.

---

### DELETE Syntax

<table>
<thead>
<tr>
<th>8.0.3-rc-debug-log</th>
<th>11</th>
</tr>
</thead>
</table>

---
If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

### Multiple-Table Syntax

```sql
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[.\*] [, tbl_name[.\*]] ...
FROM table_references
  [WHERE where_condition]
```

```sql
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name[.\*] [, tbl_name[.\*]] ...
  USING table_references
  [WHERE where_condition]
```

### Privileges

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause.

### Performance

When you do not need to know the number of deleted rows, the `TRUNCATE TABLE` statement is a faster way to empty a table than a `DELETE` statement with no `WHERE` clause. Unlike `DELETE`, `TRUNCATE TABLE` cannot be used within a transaction or if you have a lock on the table. See Section 13.1.37, “TRUNCATE TABLE Syntax” and Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”.

The speed of delete operations may also be affected by factors discussed in Section 8.2.5.3, “Optimizing DELETE Statements”.

To ensure that a given `DELETE` statement does not take too much time, the MySQL-specific `LIMIT row_count` clause for `DELETE` specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

### Subqueries

You cannot delete from a table and select from the same table in a subquery.

### Partitioned Table Support

`DELETE` supports explicit partition selection using the `PARTITION` option, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0);` in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` option can also be used in multiple-table `DELETE` statements. You can use up to one such option per table named in the `FROM` option.
DELETE Syntax

For more information and examples, see Section 23.5, “Partition Selection”.

Auto-Increment Columns

If you delete the row containing the maximum value for an AUTO_INCREMENT column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with DELETE FROM tbl_name (without a WHERE clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 15.6.1.4, “AUTO_INCREMENT Handling in InnoDB”.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, “Using AUTO_INCREMENT”.

Modifiers

The DELETE statement supports the following modifiers:

• If you specify the LOW_PRIORITY modifier, the server delays execution of the DELETE until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

• For MyISAM tables, if you use the QUICK modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

• The IGNORE modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of IGNORE are returned as warnings. For more information, see Comparison of the IGNORE Keyword and Strict SQL Mode.

Order of Deletion

If the DELETE statement includes an ORDER BY clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with LIMIT. For example, the following statement finds rows matching the WHERE clause, sorts them by timestamp_column, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:

   ```
   INSERT INTO t_copy SELECT * FROM t WHERE ...
   ```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:
RENAME TABLE t TO t_old, t_copy TO t;

3. Drop the original table:

DROP TABLE t_old;

No other sessions can access the tables involved while \texttt{RENAME TABLE} executes, so the rename operation is not subject to concurrency problems. See Section 13.1.36, “RENAME TABLE Syntax”.

\section*{MyISAM Tables}

In MyISAM tables, deleted rows are maintained in a linked list and subsequent \texttt{INSERT} operations reuse old row positions. To reclaim unused space and reduce file sizes, use the \texttt{OPTIMIZE TABLE} statement or the \texttt{myisamchk} utility to reorganize tables. \texttt{OPTIMIZE TABLE} is easier to use, but \texttt{myisamchk} is faster. See Section 13.7.3.4, “OPTIMIZE TABLE Syntax”, and Section 4.6.4, “\texttt{myisamchk} — MyISAM Table-Maintenance Utility”.

The \texttt{QUICK} modifier affects whether index leaves are merged for delete operations. \texttt{DELETE QUICK} is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

\texttt{DELETE QUICK} is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of \texttt{QUICK} can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed \texttt{AUTO_INCREMENT} column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.

3. Delete a block of rows at the low end of the column range using \texttt{DELETE QUICK}.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of \texttt{QUICK}. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use \texttt{DELETE} without \texttt{QUICK}, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use \texttt{OPTIMIZE TABLE}.

If you are going to delete many rows from a table, it might be faster to use \texttt{DELETE QUICK} followed by \texttt{OPTIMIZE TABLE}. This rebuilds the index rather than performing many index block merge operations.

\section*{Multi-Table Deletes}

You can specify multiple tables in a \texttt{DELETE} statement to delete rows from one or more tables depending on the condition in the \texttt{WHERE} clause. You cannot use \texttt{ORDER BY} or \texttt{LIMIT} in a multiple-table \texttt{DELETE}. The \texttt{table_references} clause lists the tables involved in the join, as described in Section 13.2.10.2, “JOIN Syntax”.

For the first multiple-table syntax, only matching rows from the tables listed before the \texttt{FROM} clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the \texttt{FROM} clause (before the \texttt{USING} clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

\begin{verbatim}
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
\end{verbatim}
WHERE t1.id=t2.id AND t2.id=t3.id;

Or:

DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables t1 and t2.

The preceding examples use INNER JOIN, but multiple-table DELETE statements can use other types of join permitted in SELECT statements, such as LEFT JOIN. For example, to delete rows that exist in t1 that have no match in t2, use a LEFT JOIN:

DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;

The syntax permits .* after each tbl_name for compatibility with Access.

If you use a multiple-table DELETE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the ON DELETE capabilities that InnoDB provides to cause the other tables to be modified accordingly.

Note

If you declare an alias for a table, you must use the alias when referring to the table:

DELETE t1 FROM test AS t1, test2 WHERE ...

Table aliases in a multiple-table DELETE should be declared only in the table_references part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

Incorrect:

DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;

Table aliases are also supported for single-table DELETE statements beginning with MySQL 8.0.16. (Bug #89410,Bug #27455809)

13.2.3 DO Syntax

DO expr [, expr] ...
**HANDLER Syntax**

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT expr, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as **RELEASE_LOCK()**.

Example: This **SELECT** statement pauses, but also produces a result set:

```sql
mysql> SELECT SLEEP(5);
+----------+
<table>
<thead>
<tr>
<th>SLEEP(5)</th>
</tr>
</thead>
</table>
+----------+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set:

```sql
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

### 13.2.4 HANDLER Syntax

The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for InnoDB and MyISAM tables.

The **HANDLER ... OPEN** statement opens a table, making it accessible using subsequent **HANDLER ... READ** statements. This table object is not shared by other sessions and is not closed until the session calls **HANDLER ... CLOSE** or the session terminates.

If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using **mydb.mytable**, further references must use **mytable**.

The first **HANDLER ... READ** syntax fetches a row where the index specified satisfies the given values and the **WHERE** condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index **my_idx** includes three columns named **col_a**, **col_b**, and **col_c**, in that order. The **HANDLER** statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:
HANDLER Syntax

HANDLER ... READ my_idx = (col_a_val, col_b_val, col_c_val) ...
HANDLER ... READ my_idx = (col_a_val, col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...

To employ the HANDLER interface to refer to a table’s PRIMARY KEY, use the quoted identifier `PRIMARY`:

HANDLER tbl_name READ `PRIMARY` ...

The second HANDLER ... READ syntax fetches a row from the table in index order that matches the WHERE condition.

The third HANDLER ... READ syntax fetches a row from the table in natural row order that matches the WHERE condition. It is faster than HANDLER tbl_name READ index_name when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a LIMIT clause, all forms of HANDLER ... READ fetch a single row if one is available. To return a specific number of rows, include a LIMIT clause. It has the same syntax as for the SELECT statement. See Section 13.2.10, “SELECT Syntax”.

HANDLER ... CLOSE closes a table that was opened with HANDLER ... OPEN.

There are several reasons to use the HANDLER interface instead of normal SELECT statements:

• HANDLER is faster than SELECT:
  • A designated storage engine handler object is allocated for the HANDLER ... OPEN. The object is reused for subsequent HANDLER statements for that table; it need not be reinitialized for each one.
  • There is less parsing involved.
  • There is no optimizer or query-checking overhead.
  • The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that SELECT does not normally permit.
  • HANDLER makes it easier to port to MySQL applications that use a low-level ISAM-like interface. (See Section 15.19, “InnoDB memcached Plugin” for an alternative way to adapt applications that use the key-value store paradigm.)
  • HANDLER enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with SELECT. The HANDLER interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

HANDLER is a somewhat low-level statement. For example, it does not provide consistency. That is, HANDLER ... OPEN does not take a snapshot of the table, and does not lock the table. This means that after a HANDLER ... OPEN statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to HANDLER ... NEXT or HANDLER ... PREV scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

• Any session executes FLUSH TABLES or DDL statements on the handler’s table.
• The session in which the handler is open executes non-HANDLER statements that use tables.
TRUNCATE TABLE for a table closes all handlers for the table that were opened with HANDLER OPEN.

If a table is flushed with FLUSH TABLES tbl_name WITH READ LOCK was opened with HANDLER, the handler is implicitly flushed and loses its position.

13.2.5 IMPORT TABLE Syntax

```
IMPORT TABLE FROM sdi_file [, sdi_file] ...
```

The IMPORT TABLE statement imports MyISAM tables based on information contained in .sdi (Serialized Dictionary Information) metadata files. IMPORT TABLE requires the FILE privilege to read the .sdi and table content files, and the CREATE privilege for the table to be created.

Tables can be exported from one server using mysqldump to write a file of SQL statements and imported into another server using mysql to process the dump file. IMPORT TABLE provides a faster alternative using the “raw” table files.

Prior to import, the files that provide the table content must be placed in the appropriate schema directory for the import server, and the .sdi file must be located in a directory accessible to the server. For example, the .sdi file can be placed in the directory named by the secure_file_priv system variable, or (if secure_file_priv is empty) in a directory under the server data directory.

The following example describes how to export MyISAM tables named employees and managers from the hr schema of one server and import them into the hr schema of another server. The example uses these assumptions (to perform a similar operation on your own system, modify the path names as appropriate):

- For the export server, export_basedir represents its base directory, and its data directory is export_basedir/data.
- For the import server, import_basedir represents its base directory, and its data directory is import_basedir/data.
- Table files are exported from the export server into the /tmp/export directory and this directory is secure (not accessible to other users).
- The import server uses /tmp/mysql-files as the directory named by its secure_file_priv system variable.

To export tables from the export server, use this procedure:

1. Ensure a consistent snapshot by executing this statement to lock the tables so that they cannot be modified during export:

```
mysql> FLUSH TABLES hr.employees, hr.managers WITH READ LOCK;
```

While the lock is in effect, the tables can still be used, but only for read access.

2. At the file system level, copy the .sdi and table content files from the hr schema directory to the secure export directory:

- The .sdi file is located in the hr schema directory, but might not have exactly the same basename as the table name. For example, the .sdi files for the employees and managers tables might be named employees_125.sdi and managers_238.sdi.
- For a MyISAM table, the content files are its .MYD data file and .MYI index file.
IMPORT TABLE Syntax

Given those file names, the copy commands look like this:

```
shell> cd export_basedir/data/hr
shell> cp employees_125.sdi /tmp/export
shell> cp managers_238.sdi /tmp/export
shell> cp employees.{MYD,MYI} /tmp/export
shell> cp managers.{MYD,MYI} /tmp/export
```

3. Unlock the tables:

```
mysql> UNLOCK TABLES;
```

To import tables into the import server, use this procedure:

1. The import schema must exist. If necessary, execute this statement to create it:

```
mysql> CREATE SCHEMA hr;
```

2. At the file system level, copy the .sdi files to the import server secure_file_priv directory, /tmp/mysql-files. Also, copy the table content files to the hr schema directory:

```
shell> cd /tmp/export
shell> cp employees_125.sdi /tmp/mysql-files
shell> cp managers_238.sdi /tmp/mysql-files
shell> cp employees.{MYD,MYI} import_basedir/data/hr
shell> cp managers.{MYD,MYI} import_basedir/data/hr
```

3. Import the tables by executing an IMPORT TABLE statement that names the .sdi files:

```
mysql> IMPORT TABLE FROM '/tmp/mysql-files/employees.sdi',
            '/tmp/mysql-files/managers.sdi';
```

The .sdi file need not be placed in the import server directory named by the secure_file_priv system variable if that variable is empty; it can be in any directory accessible to the server, including the schema directory for the imported table. If the .sdi file is placed in that directory, however, it may be rewritten; the import operation creates a new .sdi file for the table, which will overwrite the old .sdi file if the operation uses the same file name for the new file.

Each sdi_file value must be a string literal that names the .sdi file for a table or is a pattern that matches .sdi files. If the string is a pattern, any leading directory path and the .sdi file name suffix must be given literally. Pattern characters are permitted only in the base name part of the file name:

- ? matches any single character
- * matches any sequence of characters, including no characters

Using a pattern, the previous IMPORT TABLE statement could have been written like this (assuming that the /tmp/mysql-files directory contains no other .sdi files matching the pattern):

```
IMPORT TABLE FROM '/tmp/mysql-files/*.sdi';
```

To interpret the location of .sdi file path names, the server uses the same rules for IMPORT TABLE as the server-side rules for LOAD DATA (that is, the non-LOCAL rules). See Section 13.2.7, “LOAD DATA Syntax”, paying particular attention to the rules used to interpret relative path names.
**IMPORT TABLE** fails if the .sdi or table files cannot be located. After importing a table, the server attempts to open it and reports as warnings any problems detected. To attempt a repair to correct any reported issues, use **REPAIR TABLE**.

**IMPORT TABLE** is not written to the binary log.

### Restrictions and Limitations

**IMPORT TABLE** applies only to non-TEMPORARY MyISAM tables. It does not apply to tables created with a transactional storage engine, tables created with **CREATE TEMPORARY TABLE**, or views.

The table data and index files must be placed in the schema directory for the import server prior to the import operation, unless the table as defined on the export server uses the **DATA DIRECTORY** or **INDEX DIRECTORY** table options. In that case, modify the import procedure using one of these alternatives before executing the **IMPORT TABLE** statement:

- Put the data and index files into the same directory on the import server host as on the export server host, and create symlinks in the import server schema directory to those files.
- Put the data and index files into an import server host directory different from that on the export server host, and create symlinks in the import server schema directory to those files. In addition, modify the .sdi file to reflect the different file locations.
- Put the data and index files into the schema directory on the import server host, and modify the .sdi file to remove the data and index directory table options.

Any collation IDs stored in the .sdi file must refer to the same collations on the export and import servers.

Trigger information for a table is not serialized into the table .sdi file, so triggers are not restored by the import operation.

Some edits to an .sdi file are permissible prior to executing the **IMPORT TABLE** statement, whereas others are problematic or may even cause the import operation to fail:

- Changing the data directory and index directory table options is required if the locations of the data and index files differ between the export and import servers.
- Changing the schema name is required to import the table into a different schema on the import server than on the export server.
- Changing schema and table names may be required to accommodate differences between file system case-sensitivity semantics on the export and import servers or differences in lower_case_table_names settings. Changing the table names in the .sdi file may require renaming the table files as well.
- In some cases, changes to column definitions are permitted. Changing data types is likely to cause problems.

### 13.2.6 INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
VALUES | VALUE} (value_list) [, (value_list)] ...
[ON DUPLICATE KEY UPDATE assignment_list]
```
INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  SET assignment_list
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

value_list:
  value [, value] ...

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

**INSERT** inserts new rows into an existing table. The **INSERT ... VALUES** and **INSERT ... SET** forms of the statement insert rows based on explicitly specified values. The **INSERT ... SELECT** form inserts rows selected from another table or tables. **INSERT** with an **ON DUPLICATE KEY UPDATE** clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**.

For additional information about **INSERT ... SELECT** and **INSERT ... ON DUPLICATE KEY UPDATE**, see Section 13.2.6.1, “**INSERT ... SELECT Syntax**”, and Section 13.2.6.2, “**INSERT ... ON DUPLICATE KEY UPDATE Syntax**”.

In MySQL 8.0, the **DELAYED** keyword is accepted but ignored by the server. For the reasons for this, see Section 13.2.6.3, “**INSERT DELAYED Syntax**”.

Inserting into a table requires the **INSERT** privilege for the table. If the **ON DUPLICATE KEY UPDATE** clause is used and a duplicate key causes an **UPDATE** to be performed instead, the statement requires the **UPDATE** privilege for the columns to be updated. For columns that are read but not modified you need only the **SELECT** privilege (such as for a column referenced only on the right hand side of an `col_name = expr` assignment in an **ON DUPLICATE KEY UPDATE** clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The **PARTITION** option takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given **INSERT** statement do not match one of the partitions listed, the **INSERT** statement fails with the error **Found a row not matching the given partition set**. For more information and examples, see Section 23.5, “**Partition Selection**”.

You can use **REPLACE** instead of **INSERT** to overwrite old rows. **REPLACE** is the counterpart to **INSERT IGNORE** in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See Section 13.2.9, “**REPLACE Syntax**”.

**tbl_name** is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the **VALUES** list or the **SELECT** statement.
• If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.

• A `SET` clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

• If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.7, “Data Type Default Values”. See also Section 1.8.3.3, “Constraints on Invalid Data”.

If strict SQL mode is enabled, an `INSERT` statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.11, “Server SQL Modes”.

• If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

• Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the `VALUES` list.

• If a generated column is inserted into explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see Section 13.1.20.9, “CREATE TABLE and Generated Columns”.

• In expressions, you can use `DEFAULT(col_name)` to produce the default value for column `col_name`.

• Type conversion of an expression `expr` that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column inserts the value `1999`, `19.9921`, `19.992100`, or `1999`, respectively. The value stored in the `INT` and `YEAR` columns is `1999` because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the `FLOAT` and `DECIMAL` columns, the string-to-number conversion considers the entire string a valid numeric value.

• An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

An exception occurs for columns that contain `AUTO_INCREMENT` values. Because `AUTO_INCREMENT` values are generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.
**INSERT Syntax**

**INSERT** statements that use **VALUES** syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```sql
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```sql
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

**VALUE** is a synonym for **VALUES** in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

The affected-rows value for an **INSERT** can be obtained using the **ROW_COUNT()** SQL function or the mysql_affected_rows() C API function. See Section 12.15, “Information Functions”, and Section 28.7.7.1, “mysql_affected_rows()”.

If you use an **INSERT ... VALUES** statement with multiple value lists or **INSERT ... SELECT**, the statement returns an information string in this format:

- **Records**: \( N_1 \)
- **Duplicates**: \( N_2 \)
- **Warnings**: \( N_3 \)

If you are using the C API, the information string can be obtained by invoking the mysql_info() function. See Section 28.7.7.36, “mysql_info()”.

**Records** indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be nonzero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. **Warnings** can occur under any of the following conditions:

- Inserting **NULL** into a column that has been declared **NOT NULL**. For multiple-row **INSERT** statements or **INSERT INTO ... SELECT** statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. **INSERT INTO ... SELECT** statements are handled the same way as multiple-row inserts because the server does not examine the result set from the **SELECT** to see whether it returns a single row. (For a single-row **INSERT**, no warning occurs when **NULL** is inserted into a **NOT NULL** column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.

- Inserting a string into a string column (**CHAR**, **VARCHAR**, **TEXT**, or **BLOB**) that exceeds the column's maximum length. The value is truncated to the column's maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.
For `INSERT` examples involving `AUTO_INCREMENT` column values, see Section 3.6.9, “Using `AUTO_INCREMENT`”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function.

**Note**

These two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in Section 12.15, “Information Functions”, and Section 28.7.7.38, “`mysql_insert_id()`”.

The `INSERT` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time.

  `LOW_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

  **Note**

  `LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See Section 8.11.3, “Concurrent Inserts”.

- If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, “Concurrent Inserts”.

  `HIGH_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` modifier, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors generate warnings instead.

  `IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error. When `INSERT IGNORE` is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 23.2.2, “LIST Partitioning”.

  Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

  For more information, see Comparison of the `IGNORE` Keyword and Strict SQL Mode.

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API
INSERT Syntax

function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”.

- **INSERT DELAYED** was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 8.0, the `DELAYED` modifier is accepted but ignored. Use `INSERT` (without `DELAYED`) instead. See Section 13.2.6.3, “INSERT DELAYED Syntax”.

An `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see Partitioning and Locking.

**13.2.6.1 INSERT ... SELECT Syntax**

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [[(col_name [, col_name] ...)]
    SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from the result of a `SELECT` statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement. See Section 8.4.4, “Internal Temporary Table Use in MySQL”, and Section B.6.6.2, “TEMPORARY Table Problems”.

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see Section 8.11.3, “Concurrent Inserts”).
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.
You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` option following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the `INSERT ... SELECT` statement fails. For more information and examples, see Section 23.5, “Partition Selection”.

For `INSERT ... SELECT` statements, see Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Syntax” for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause.

The order in which a `SELECT` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the master and the slave. See also Section 17.4.1.18, “Replication and LIMIT”.

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Partitioning and Locking.

13.2.6.2 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value 1, the following two statements have similar effect:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;
```

```
UPDATE t1 SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only one row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the
CLIENT_FOUND_ROWS flag to the mysql_real_connect() C API function when connecting to mysqld, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an AUTO_INCREMENT column and INSERT ... ON DUPLICATE KEY UPDATE inserts or updates a row, the LAST_INSERT_ID() function returns the AUTO_INCREMENT value.

The ON DUPLICATE KEY UPDATE clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the ON DUPLICATE KEY UPDATE clause, you can use the VALUES(col_name) function to refer to column values from the INSERT portion of the INSERT ... ON DUPLICATE KEY UPDATE statement. In other words, VALUES(col_name) in the ON DUPLICATE KEY UPDATE clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The VALUES() function is meaningful only in the ON DUPLICATE KEY UPDATE clause or INSERT statements and returns NULL otherwise.

Example:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

For INSERT ... SELECT statements, these rules apply regarding acceptable forms of SELECT query expressions that you can refer to in an ON DUPLICATE KEY UPDATE clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from DISTINCT queries.
- References to columns in other tables, as long as the SELECT does not use GROUP BY. One side effect is that you must qualify references to nonunique column names.

References to columns from a UNION are not supported. To work around this restriction, rewrite the UNION as a derived table so that its rows can be treated as a single-table result set. For example, this statement produces an error:

```sql
INSERT INTO t1 (a, b)
SELECT c, d FROM t2
UNION
SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the UNION as a derived table:

```sql
INSERT INTO t1 (a, b)
SELECT * FROM
  (SELECT c, d FROM t2
  UNION
  SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT` statements for the master and the slave to diverge. Thus, `INSERT ... ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 17.2.1.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

An `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Partitioning and Locking.

13.2.6.3 INSERT DELAYED Syntax

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.0, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning ("INSERT DELAYED is no longer supported. The statement was converted to INSERT"). The `DELAYED` keyword is scheduled for removal in a future release.

13.2.7 LOAD DATA Syntax

```
LOAD DATA
[LOW_PRIORITY | CONCURRENT] [LOCAL]
INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[CHARACTER SET charset_name]
[[FIELDS | COLUMNS]
 [TERMINATED BY 'string']
 [[OPTIONALLY] ENCLOSED BY 'char']
 [ESCAPED BY 'char']
]
[LINES
 [STARTING BY 'string']
 [TERMINATED BY 'string']
]
[IGNORE number [LINES | ROWS]]
```
The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. `LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.10.1, "SELECT ... INTO Syntax".) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

You can also load data files by using the `mysqlimport` utility; see Section 4.5.5, "mysqlimport — A Data Import Program". `mysqlimport` operates by sending a `LOAD DATA` statement to the server.

For more information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see Section 8.2.5.1, "Optimizing INSERT Statements".

- Partitioned Table Support

- Concurrency Considerations
- Duplicate-Key Handling
- Index Handling
- Field and Line Handling
- Column List Specification
- Input Preprocessing
- Statement Result Information
- Miscellaneous Topics

### Partitioned Table Support

`LOAD DATA` supports explicit partition selection using the `PARTITION` option with a list of one or more comma-separated names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 23.5, "Partition Selection".

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines that employ row-level locking, such as `InnoDB`. For more information, see Partitioning and Locking.

### Input File Name, Location, and Content Interpretation

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name character set.

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is
usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies "no conversion."

`LOAD DATA` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA`.

Note

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

**Concurrency Considerations**

If you use the `LOW_PRIORITY` modifier, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify the `CONCURRENT` modifier with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This modifier affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

For information about `LOAD DATA` in relation to replication, see Section 17.4.1.19, "Replication and LOAD DATA".

The `LOCAL` modifier affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` does not work. See Section 6.1.6, "Security Issues with LOAD DATA LOCAL".

The `LOCAL` modifier affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

  When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the directory where the MySQL server stores temporary files. See Section B.6.3.5, "Where MySQL Stores Temporary Files". Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:

  - If the file name is an absolute path name, the server uses it as given.
  
  - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
  
  - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database.
database. For example, if db1 is the default database, the following LOAD DATA statement reads the file data.txt from the database directory for db1, even though the statement explicitly loads the file into a table in the db2 database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Note
The server also uses the non-LOCAL rules to locate .sdi files for the IMPORT TABLE statement.

Non-LOCAL load operations read text files located on the server. For security reasons, such operations require that you have the FILE privilege. See Section 6.2.1, “Privileges Provided by MySQL”. Also, non-LOCAL load operations are subject to the secure_file_priv system variable setting. If the variable value is a nonempty directory name, the file to be loaded must be located in that directory. If the variable value is empty (which is insecure), the file need only be readable by the server.

Using LOCAL is a bit slower than letting the server access the files directly, because the file contents must be sent over the connection by the client to the server. On the other hand, you do not need the FILE privilege to load local files.

LOCAL also affects error handling:

- With LOAD DATA, data-interpretation and duplicate-key errors terminate the operation.
- With LOAD DATA LOCAL, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if IGNORE is specified. IGNORE is explained further later in this section.

Duplicate-Key Handling
The REPLACE and IGNORE modifiers control handling of input rows that duplicate existing rows on unique key values:

- If you specify REPLACE, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See Section 13.2.9, “REPLACE Syntax”.
- If you specify IGNORE, rows that duplicate an existing row on a unique key value are discarded. For more information, see Comparison of the IGNORE Keyword and Strict SQL Mode.
- If you do not specify either modifier, the behavior depends on whether the LOCAL modifier is specified. Without LOCAL, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With LOCAL, the default behavior is the same as if IGNORE is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

Index Handling
To ignore foreign key constraints during the load operation, execute a SET foreign_key_checks = 0 statement before executing LOAD DATA.

If you use LOAD DATA on an empty MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). Normally, this makes LOAD DATA much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with ALTER TABLE ... DISABLE KEYS before loading the file into the table and using ALTER TABLE ... ENABLE KEYS to re-create the indexes after loading the file. See Section 8.2.5.1, “Optimizing INSERT Statements”. 2284
Field and Line Handling

For both the LOAD DATA and SELECT ... INTO OUTFILE statements, the syntax of the FIELDS and LINES clauses is the same. Both clauses are optional, but FIELDS must precede LINES if both are specified.

If you specify a FIELDS clause, each of its subclauses (TERMINATED BY, [OPTIONALLY] ENCLOSED BY, and ESCAPED BY) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no FIELDS or LINES clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences '\t' and '\n' specify tab and newline characters, respectively.

In other words, the defaults cause LOAD DATA to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character \ as escape sequences. For example, \t, \n, and \\ signify tab, newline, and backslash, respectively. See the discussion of FIELDS ESCAPED BY later for the full list of escape sequences.

Conversely, the defaults cause SELECT ... INTO OUTFILE to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use \ to escape instances of tab, newline, or \ that occur within field values.
- Write newlines at the ends of lines.

Note

For a text file generated on a Windows system, proper file reading might require LINES TERMINATED BY '
' because Windows programs typically use two characters as a line terminator. Some programs, such as WordPad, might use \r as a line terminator when writing files. To read such files, use LINES TERMINATED BY ''.

If all the input lines have a common prefix that you want to ignore, you can use LINES STARTING BY 'prefix_string' to skip the prefix and anything before it. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',',
  LINES STARTING BY 'xxx';
```
If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be ("abc", 1) and ("def", 2). The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
    FIELDS TERMINATED BY ','
    FROM table2;
```

To read the comma-delimited file, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
    FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
    FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
    FIELDS TERMINATED BY ',' ENCLOSED BY '"'
    LINES TERMINATED BY '
'
    IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED` option.

Any of the field- or line-handling options can specify an empty string (`''`). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.
To read a file containing jokes that are separated by lines consisting of `%%`, you can do this:

```sql
CREATE TABLE jokes
(a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
FIELDS TERMINATED BY ''
LINES TERMINATED BY '
%%
' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (SELECT ... INTO OUTFILE), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a " quote","102.20"
"4","a string containing a ", quote and comma","102.20"
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a ", quote",102.20
4,"a string containing a "", quote and comma",102.20
```

Occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also, if you specify an empty `ESCAPED BY` value, it is possible to inadvertently generate output that cannot be read properly by `LOAD DATA`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.

If the field begins with the `ENCLOSED BY` character, instances of that character are recognized as terminating a field value only if followed by the field or line `TERMINATED BY` sequence. To avoid ambiguity, occurrences of the `ENCLOSED BY` character within a field value can be doubled and are interpreted as a single instance of the character. For example, if `ENCLOSED BY '"'` is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss     -> The "BIG" boss
The ""BIG"" boss    -> The ""BIG"" boss
```

`FIELDS ESCAPED BY` controls how to read or write special characters:

- For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that
are exceptions, where the first character is the escape character. These sequences are shown in the following table (using \ for the escape character). The rules for NULL handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
<tr>
<td>\N</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For more information about \-escape syntax, see Section 9.1.1, “String Literals”.

If the FIELDS ESCAPED BY character is empty, escape-sequence interpretation does not occur.

- For output, if the FIELDS ESCAPED BY character is not empty, it is used to prefix the following characters on output:
  - The FIELDS ESCAPED BY character.
  - The FIELDS [OPTIONALLY] ENCLOSED BY character.
  - The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values, if the ENCLOSED BY character is empty or unspecified.
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If LINES TERMINATED BY is an empty string and FIELDS TERMINATED BY is nonempty, lines are also terminated with FIELDS TERMINATED BY.

- If the FIELDS TERMINATED BY and FIELDS ENCLOSED BY values are both empty (''), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

  LINES TERMINATED BY is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ''. In this case, the text file must contain all fields for each row.

  Fixed-row format also affects handling of NULL values, as described later.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-size format does not work if you are using a multibyte character set.</td>
</tr>
</tbody>
</table>
Handling of **NULL** values varies according to the **FIELDS** and **LINES** options in use:

- For the default **FIELDS** and **LINES** values, **NULL** is written as a field value of `\N` for output, and a field value of `\N` is read as **NULL** for input (assuming that the **ESCAPED BY** character is `\`).

- If **FIELDS ENCLOSED BY** is not empty, a field containing the literal word **NULL** as its value is read as a **NULL** value. This differs from the word **NULL** enclosed within **FIELDS ENCLOSED BY** characters, which is read as the string 'NULL'.

- If **FIELDS ESCAPED BY** is empty, **NULL** is written as the word **NULL**.

- With fixed-row format (which is used when **FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** are both empty), **NULL** is written as an empty string. This causes both **NULL** values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load **NULL** into a **NOT NULL** column causes assignment of the implicit default value for the column’s data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in Section 11.7, “Data Type Default Values”.

Some cases are not supported by **LOAD DATA**:

- Fixed-size rows (**FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** both empty) and **BLOB** or **TEXT** columns.

- If you specify one separator that is the same as or a prefix of another, **LOAD DATA** cannot interpret the input properly. For example, the following **FIELDS** clause would cause problems:

  ```sql
  FIELDS TERMINATED BY '' ENCLOSED BY ''
  ```

- If **FIELDS ESCAPED BY** is empty, a field value that contains an occurrence of **FIELDS ENCLOSED BY** or **LINES TERMINATED BY** followed by the **FIELDS TERMINATED BY** value causes **LOAD DATA** to stop reading a field or line too early. This happens because **LOAD DATA** cannot properly determine where the field or line value ends.

### Column List Specification

The following example loads all columns of the `persondata` table:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the **LOAD DATA** statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

### Input Preprocessing

Each `col_name_or_user_var` value is either a column name or a user variable. With user variables, the **SET** clause enables you to perform preprocessing transformations on their values before assigning the result to columns.
User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```sql
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```sql
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```sql
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in Section 11.7, “Data Type Default Values”.

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.3, “Date and Time Types”.
These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `''` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b` and trailing `b` and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```shell
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
  INTO TABLE bit_test (@var1)
    SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
mysql>
```

For `BIT` values in `0b` binary notation (for example, `0b011010`), use this `SET` clause instead to strip off the leading `0b`:

```sql
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

**Statement Result Information**

When the `LOAD DATA` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see Section 13.2.6, “INSERT Syntax”), except that `LOAD DATA` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.7.6.40, “SHOW WARNINGS Syntax”.

2291
If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See Section 28.7.7.36, "mysql_info()".

**Miscellaneous Topics**

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

### 13.2.8 LOAD XML Syntax

```
LOAD XML
  [LOW_PRIORITY | CONCURRENT] [LOCAL]
  INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE [db_name.]tbl_name
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<tagname>']
  [IGNORE number {LINES | ROWS}]
  ([field_name_or_user_var[, field_name_or_user_var] ...])
  [SET col_name={expr | DEFAULT},[, col_name={expr | DEFAULT}] ...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (`<` and `>`).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:
  ```
  <row column1="value1" column2="value2" .../>
  ```

- Column names as tags and column values as the content of these tags:
  ```
  <row
  ```
• Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```xml
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

• `LOW_PRIORITY` or `CONCURRENT`  
• `LOCAL`  
• `REPLACE` or `IGNORE`  
• `CHARACTER SET`  
• `SET`  

See Section 13.2.7, “LOAD DATA Syntax”, for more information about these clauses.

`(field_name_or_user_var, ...)` is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```sql
USE test;
CREATE TABLE person (  
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);  
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```xml
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
</list>
```
Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
    -> INTO TABLE person
    -> ROWS IDENTIFIED BY '<person>';
Query OK, 8 rows affected (0.00 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
|-----------+--------+------------+---------------------|
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likame | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sraref | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>
```
LOAD XML Syntax

```
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <row>
        <field name="person_id">1</field>
        <field name="fname">Kapek</field>
        <field name="lname">Sainnouine</field>
    </row>
    <row>
        <field name="person_id">2</field>
        <field name="fname">Sajon</field>
        <field name="lname">Rondela</field>
    </row>
    <row>
        <field name="person_id">3</field>
        <field name="fname">Likema</field>
        <field name="lname">Örrtmons</field>
    </row>
    <row>
        <field name="person_id">4</field>
        <field name="fname">Slar</field>
        <field name="lname">Manlanth</field>
    </row>
    <row>
        <field name="person_id">5</field>
        <field name="fname">Stoma</field>
        <field name="lname">Nilu</field>
    </row>
    <row>
        <field name="person_id">6</field>
        <field name="fname">Nirtam</field>
        <field name="lname">Sklöd</field>
    </row>
    <row>
        <field name="person_id">7</field>
        <field name="fname">Sungam</field>
        <field name="lname">Dulbād</field>
    </row>
    <row>
        <field name="person_id">8</field>
        <field name="fname">Sreraf</field>
        <field name="lname">Encmelt</field>
    </row>
</resultset>
```

Note

The `--xml` option causes the mysql client to use XML formatting for its output; the `--e` option causes the client to execute the SQL statement immediately following the option. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)
mysql> LOAD XML LOCAL INFILE 'person-dump.xml' INTO TABLE person2;
```
LOAD XML Syntax

Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
|-----------+--------+------------+---------------------|
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the person2 table and dropping the created column, then using the same LOAD XML statement we just employed previously, like this:

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE person2\G
*************************** 1. row ***************************
Table: person2
Create Table: CREATE TABLE `person2` (  `person_id` int(11) NOT NULL,  `fname` varchar(40) DEFAULT NULL,  `lname` varchar(40) DEFAULT NULL,  PRIMARY KEY (`person_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml' INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+
| person_id | fname  | lname      |
|-----------+--------+------------|
|         1 | Kapek  | Sainnouine |
|         2 | Sajon  | Rondela    |
|         3 | Likema | Örrtmons   |
|         4 | Slar   | Manlanth   |
|         5 | Stoma  | Nilu       |
|         6 | Nirtam | Sklöd      |
|         7 | Sungam | Dulbåd     |
|         8 | Sreraf | Encmelt    |
+-----------+--------+------------+
8 rows in set (0.00 sec)

The order in which the fields are given within each row of the XML file does not affect the operation of LOAD XML; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.
As mentioned previously, you can use a \( \text{field-name-or-user-var}, \ldots \) list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```sql
mysql> CREATE TABLE individual (
    -> individual_id INT NOT NULL PRIMARY KEY,
    -> name1 VARCHAR(40) NULL,
    -> name2 VARCHAR(40) NULL,
    -> made TIMESTAMP
    -> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table’s columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml'
    -> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
    -> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
```

```sql
mysql> SELECT * FROM individual;
```

<table>
<thead>
<tr>
<th>individual_id</th>
<th>name1</th>
<th>name2</th>
<th>made</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>3</td>
<td>Likema</td>
<td>Örrtmons</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>5</td>
<td>Stoma</td>
<td>Nilu</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>6</td>
<td>Nirtam</td>
<td>Sklöd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>7</td>
<td>Sungam</td>
<td>Dulbåd</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>8</td>
<td>Srraf</td>
<td>Encmelt</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>

8 rows in set (0.00 sec)

The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```xml
<?xml version="1.0"?>
<list>
```
<person person_id="1">
  <fname>Robert</fname>
  <lname>Jones</lname>
  <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
  <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
</person>

<person person_id="2">
  <fname>Mary</fname>
  <lname>Smith</lname>
  <address address_id="3" street="River Road" zip="80239" city="Denver"/>
  <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
</person>
</list>

You can again use the <code>test.person</code> table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```sql
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person;
```

```plaintext
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
```

Now create an <code>address</code> table in the <code>test</code> database using the following <code>CREATE TABLE</code> statement:

```sql
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);
```

To import the data from the XML file into the <code>person</code> table, execute the following <code>LOAD XML</code> statement, which specifies that rows are to be specified by the <code>&lt;person&gt;</code> element, as shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'
  INTO TABLE person
  ROWS IDENTIFIED BY '&lt;person&gt;';
```

Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

You can verify that the records were imported using a <code>SELECT</code> statement:

```sql
mysql> SELECT * FROM person;
```

<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Robert</td>
<td>Jones</td>
<td>2007-07-24 17:37:06</td>
</tr>
</tbody>
</table>
Since the `<address>` elements in the XML file have no corresponding columns in the person table, they are skipped.

To import the data from the `<address>` elements into the address table, use the LOAD XML statement shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'
    
    INTO TABLE address
    
    ROWS IDENTIFIED BY '<address>';
```

You can see that the data was imported using a SELECT statement such as this one:

```sql
mysql> SELECT * FROM address;
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a person_id column in the address table, the value of the person_id attribute from the parent <person> element for each `<address>` is imported into the address table.

**Security Considerations.** As with the LOAD DATA statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the LOAD XML statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use LOAD XML LOCAL to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the mysql client to disable LOAD XML for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the FILE privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

**Important**

Revoking the FILE privilege (or not granting it in the first place) keeps the user only from executing the LOAD XML statement (as well as the LOAD_FILE() function; it does not prevent the user from executing LOAD XML LOCAL. To disallow this statement, you must start the server or the client with `--local-infile=OFF`. 
In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as **MyISAM**, any locks caused by **LOAD XML** perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as **InnoDB**. For more information, see **Partitioning and Locking**.

### 13.2.9 REPLACE Syntax

**REPLACE** syntax is as follows:

```sql
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [{col_name [, col_name] ...}]
  {VALUES | VALUE} (value_list) [, (value_list)] ...
```

- **LOW_PRIORITY**: Allows **REPLACE** statements to execute more quickly than **INSERT** statements. If both keys are present in a table, a **REPLACE** statement will be converted to an **INSERT** statement with **LOW_PRIORITY**.
- **DELAYED**: Inserts and replaces were deprecated in MySQL 5.6. In MySQL 8.0, **DELAYED** is not supported. The server recognizes but ignores the **DELAYED** keyword, handles the replace as a nondelayed replace, and generates an **ER_WARN_LEGACY_SYNTAX_CONVERTED** warning. (“REPLACE DELAYED is no longer supported. The statement was converted to REPLACE.”) The **DELAYED** keyword will be removed in a future release.

**REPLACE** works exactly like **INSERT**, except that if an old row in the table has the same value as a new row for a **PRIMARY KEY** or a **UNIQUE** index, the old row is deleted before the new row is inserted. See **Section 13.2.6, "INSERT Syntax"**.

**REPLACE** is a MySQL extension to the SQL standard. It either inserts, or **deletes** and inserts. For another MySQL extension to standard SQL—that either inserts or **updates**—see **Section 13.2.6.2, "INSERT ... ON DUPLICATE KEY UPDATE Syntax"**.

### Note

**REPLACE** makes sense only if a table has a **PRIMARY KEY** or **UNIQUE** index. Otherwise, it becomes equivalent to **INSERT**, because there is no index to be used to determine whether a new row duplicates another.
Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

If a generated column is replaced explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see Section 13.1.20.9, “CREATE TABLE and Generated Columns”.

`REPLACE` supports explicit partition selection using the `PARTITION` keyword with a list of comma-separated names of partitions, subpartitions, or both. As with `INSERT`, if it is not possible to insert the new row into any of these partitions or subpartitions, the `REPLACE` statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 23.5, “Partition Selection”.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_XXX` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do
this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```sql
CREATE TABLE test (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the `mysql` client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)
mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)
mysql> SELECT * FROM test;
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+------+---------------------+
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)
mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)
mysql> SELECT * FROM test2;
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Old</td>
<td>2014-08-20 18:47:00</td>
</tr>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+------+---------------------+
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement `WHERE` clause, as long as none of the table partitioning columns are updated; otherwise the entire table is locked.
SELECT Syntax

(For storage engines such as InnoDB that employ row-level locking, no locking of partitions takes place.) For more information, see Partitioning and Locking.

13.2.10 SELECT Syntax

```
SELECT [ALL | DISTINCT | DISTINCTROW ]
     [HIGH_PRIORITY]
     [STRAIGHT_JOIN]
     [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
     SQL_NO_CACHE [SQL_CALC_FOUND_ROWS]
select_expr [, select_expr ...]
[FROM table_references]
     [PARTITION partition_list]
[WHERE where_condition]
[GROUP BY {col_name | expr | position}, ... [WITH ROLLUP]]
[HAVING where_condition]
[WINDOW window_name AS (window_spec)
   [, window_name AS (window_spec)] ...]
[ORDER BY {col_name | expr | position}
   [ASC | DESC], ... [WITH ROLLUP]]
[LIMIT {offset,] row_count | row_count OFFSET offset}]
[INTO OUTFILE 'filename'
   [export_options]
   | INTO DUMPFILE 'filename'
   | INTO var_name [, var_name]]
[FOR {UPDATE | SHARE} [OF tbl_name [, tbl_name] ...] [NOWAIT | SKIP LOCKED]
 | LOCK IN SHARE MODE]
```

SELECT is used to retrieve rows selected from one or more tables, and can include UNION statements and subqueries. See Section 13.2.10.3, "UNION Syntax", and Section 13.2.11, "Subquery Syntax". A SELECT statement can start with a WITH clause to define common table expressions accessible within the SELECT. See Section 13.2.13, "WITH Syntax (Common Table Expressions)".

The most commonly used clauses of SELECT statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.
- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.10.2, "JOIN Syntax".
- SELECT supports explicit partition selection using the PARTITION with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see Section 13.2.10.2, "JOIN Syntax"). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 23.5, "Partition Selection".

SELECT ... PARTITION from tables using storage engines such as MyISAM that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the PARTITION option.

For more information, see Partitioning and Locking.

- The WHERE clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no WHERE clause.

In the WHERE expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See Section 9.5, "Expressions", and Chapter 12, Functions and Operators.
**SELECT** can also be used to retrieve rows computed without reference to any table.

For example:

```sql
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```sql
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

**DUAL** is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The exception is that the **INTO** clause can appear either as shown in the syntax description or immediately following the **select_expr** list. For more information about **INTO**, see Section 13.2.10.1, “SELECT ... INTO Syntax”.

The list of **select_expr** terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use *-shorthand:

- A select list consisting only of a single unqualified * can be used as shorthand to select all columns from all tables:
  ```sql
  SELECT * FROM t1 INNER JOIN t2 ...
  ```

- **tbl_name.** can be used as a qualified shorthand to select all columns from the named table:
  ```sql
  SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
  ```

- Use of an unqualified * with other items in the select list may produce a parse error. To avoid this problem, use a qualified **tbl_name.** reference
  ```sql
  SELECT AVG(score), t1.* FROM t1 ...
  ```

The following list provides additional information about other **SELECT** clauses:

- A **select_expr** can be given an alias using **AS alias_name**. The alias is used as the expression's column name and can be used in **GROUP BY**, **ORDER BY**, or **HAVING** clauses. For example:
  ```sql
  SELECT CONCAT(last_name,' ',first_name) AS full_name
  FROM mytable ORDER BY full_name;
  ```

  The **AS** keyword is optional when aliasing a **select_expr** with an identifier. The preceding example could have been written like this:

  ```sql
  SELECT CONCAT(last_name,' ',first_name) full_name
  FROM mytable ORDER BY full_name;
  ```

  However, because the **AS** is optional, a subtle problem can occur if you forget the comma between two **select_expr** expressions: MySQL interprets the second as an alias name. For example, in the following statement, **columnb** is treated as an alias name:
SELECT columna columnb FROM mytable;

For this reason, it is good practice to be in the habit of using AS explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section B.6.4.4, “Problems with Column Aliases”.

- The FROM table_references clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.10.2, “JOIN Syntax”. For each table specified, you can optionally specify an alias.

\[ \text{tbl}_\text{name} \quad [\text{AS} \quad \text{alias}] \quad [\text{index}\_\text{hint}] \]

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.4, “Index Hints”.

You can use SET max_seeks_for_key=value as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.8, “Server System Variables”.

- You can refer to a table within the default database as \( \text{tbl}_\text{name} \), or as \( \text{db}_\text{name}.\text{tbl}_\text{name} \) to specify a database explicitly. You can refer to a column as \( \text{col}_\text{name} \), \( \text{tbl}_\text{name}.\text{col}_\text{name} \), or \( \text{db}_\text{name}.\text{tbl}_\text{name}.\text{col}_\text{name} \). You need not specify a \( \text{tbl}_\text{name} \) or \( \text{db}_\text{name} \) prefix for a column reference unless the reference would be ambiguous. See Section 9.2.1, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

- A table reference can be aliased using \( \text{tbl}_\text{name} \ \text{AS} \ \text{alias}_\text{name} \) or \( \text{tbl}_\text{name} \ \text{alias}_\text{name} \). These statements are equivalent:

- Columns selected for output can be referred to in ORDER BY and GROUP BY clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

\[ \begin{align*}
\text{SELECT t1.name, t2.salary FROM employee AS t1, info AS t2} \\
&\quad \text{WHERE t1.name = t2.name;} \\
\text{SELECT t1.name, t2.salary FROM employee t1, info t2} \\
&\quad \text{WHERE t1.name = t2.name;}
\end{align*} \]

- To sort in reverse order, add the DESC (descending) keyword to the name of the column in the ORDER BY clause that you are sorting by. The default is ascending order; this can be specified explicitly using the ASC keyword.

If ORDER BY occurs within a subquery and also is applied in the outer query, the outermost ORDER BY takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:
(SELECT ... ORDER BY a) ORDER BY a DESC;

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- Prior to MySQL 8.0.13, MySQL supported a nonstandard syntax extension that permitted explicit `ASC` or `DESC` designators for `GROUP BY` columns. MySQL 8.0.12 and later supports `ORDER BY` with grouping functions so that use of this extension is no longer necessary. (Bug #86312, Bug #26073525) This also means you can sort on an arbitrary column or columns when using `GROUP BY`, like this:

```
SELECT a, b, COUNT(c) AS t FROM test_table GROUP BY a,b ORDER BY a,t DESC;
```

As of MySQL 8.0.13, the `GROUP BY` extension is no longer supported: `ASC` or `DESC` designators for `GROUP BY` columns are not permitted.

- When you use `ORDER BY` or `GROUP BY` to sort a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in Section 12.20, "Aggregate (GROUP BY) Functions".

- `GROUP BY` permits a `WITH ROLLUP` modifier. See Section 12.20.2, "GROUP BY Modifiers".

  Previously, it was not permitted to use `ORDER BY` in a query having a `WITH ROLLUP` modifier. This restriction is lifted as of MySQL 8.0.12. See Section 12.20.2, "GROUP BY Modifiers".

- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`).

  The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

  If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

  Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

  Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:
SELECT user, MAX(salary) FROM users GROUP BY user HAVING MAX(salary) > 10;

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- The `WINDOW` clause, if present, defines named windows that can be referred to by window functions. For details, see Section 12.21.4, “Named Windows”.
