The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is neccessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

**Simple replication.** The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See Section 17.1.3.4, “Setting Up Replication Using GTIDs”, for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

**Copying data and transactions to the slave.** Executing the entire transaction history can be time-consuming when the source server has processed a large number of transactions previously, and this can represent a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the source server contains can be imported to the new slave. The source server can be either the master or the slave, but you must ensure that the source has processed all required transactions before copying the data.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transfered to the slave, as outlined here:

**Data Set**

1. Create a dump file using `mysqldump` on the source server. Set the `mysqldump` option `--master-data` (with the default value of 1) to include a `CHANGE MASTER TO` statement with binary logging information. Set the `--set-gtid-purged` option to `AUTO` (the default) or `ON`, to include information about executed transactions in the dump. Then use the `mysql` client to import the dump file on the target server.

2. Alternatively, create a data snapshot of the source server using raw data files, then copy these files to the target server, following the instructions in Section 17.1.2.5, “Choosing a Method for Data Snapshots”. If you use InnoDB tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial
Replication with Global Transaction Identifiers

Product that is included as part of a MySQL Enterprise subscription. See Section 30.2, “MySQL Enterprise Backup Overview” for detailed information.

3. Alternatively, stop both the source and target servers, copy the contents of the source's data directory to the new slave's data directory, then restart the slave. If you use this method, the slave must be configured for GTID-based replication, in other words with gtid_mode=ON. For instructions and important information for this method, see Section 17.1.2.8, “Adding Slaves to a Replication Environment”.

Transaction History

If the source server has a complete transaction history in its binary logs (that is, the GTID set @@GLOBAL.gtid_purged is empty), you can use these methods.

1. Import the binary logs from the source server to the new slave using mysqlbinlog, with the --read-from-remote-server and --read-from-remote-master options.

2. Alternatively, copy the source server’s binary log files to the slave. You can make copies from the slave using mysqlbinlog with the --read-from-remote-server and --raw options. These can be read into the slave by using mysqlbinlog > file (without the --raw option) to export the binary log files to SQL files, then passing these files to the mysql client for processing. Ensure that all of the binary log files are processed using a single mysql process, rather than multiple connections. For example:

   shell> mysqlbinlog copied-binlog.000001 copied-binlog.000002 | mysql -u root -p

For more information, see Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”.

This method has the advantage that a new server is available almost immediately: only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave’s availability is not instantaneously, but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

Injecting empty transactions. The master’s global gtid_executed variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of gtid_executed on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master’s gtid_executed, like this:

   SET GTID_NEXT='aaa-bbb-ccc-ddd:N';
   BEGIN;
   COMMIT;
Replication with Global Transaction Identifiers

SET GTID_NEXT='AUTOMATIC';

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave’s binary logs, as shown here, where \( N \) is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000\N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with `gtid_purged`.** The master’s global `gtid_purged` variable contains the set of all transactions that have been purged from the master’s binary log. As with the method discussed previously (see *Injecting empty transactions*), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.

**Restoring GTID mode slaves.** When restoring a slave in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the slave and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*!*;/`, so set it back:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET GTID_NEXT=automatic;
mysql> RESET SLAVE;
mysql> START SLAVE;
```

### 17.1.3.6 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.
Replication with Global Transaction Identifiers

Updates involving nontransactional storage engines. When using GTIDs, updates to tables using nontransactional storage engines such as MyISAM cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as InnoDB.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not. Also be aware that triggers that are defined to operate on nontransactional tables can be the cause of these problems.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

CREATE TABLE ... SELECT statements. CREATE TABLE ... SELECT statements are not allowed when using GTID-based replication. When binlog_format is set to STATEMENT, a CREATE TABLE ... SELECT statement is recorded in the binary log as one transaction with one GTID, but if ROW format is used, the statement is recorded as two transactions with two GTIDs. If a master used STATEMENT format and a slave used ROW format, the slave would be unable to handle the transaction correctly, therefore the CREATE TABLE ... SELECT statement is disallowed with GTIDs to prevent this scenario.

Temporary tables. When binlog_format is set to STATEMENT, CREATE TEMPORARY TABLE and DROP TEMPORARY TABLE statements cannot be used inside transactions, procedures, functions, and triggers when GTIDs are in use on the server (that is, when the enforce_gtid_consistency system variable is set to ON). They can be used outside these contexts when GTIDs are in use, provided that autocommit=1 is set. From MySQL 8.0.13, when binlog_format is set to ROW or MIXED, CREATE TEMPORARY TABLE and DROP TEMPORARY TABLE statements are allowed inside a transaction, procedure, function, or trigger when GTIDs are in use. The statements are not written to the binary log and are therefore not replicated to slaves. The use of row-based replication means that the slaves remain in sync without the need to replicate temporary tables. If the removal of these statements from a transaction results in an empty transaction, the transaction is not written to the binary log.

Preventing execution of unsupported statements. To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the --enforce-gtid-consistency option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

Note that --enforce-gtid-consistency only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For information about other required startup options when enabling GTIDs, see Section 17.1.3.4, “Setting Up Replication Using GTIDs”.

Skipping transactions. sql_slave_skip_counter is not supported when using GTIDs. If you need to skip transactions, use the value of the master’s gtid_executed variable instead; see Injecting empty transactions, for more information.

Ignoring servers. The IGNORE_SERVER_IDS option of the CHANGE MASTER TO statement is deprecated when using GTIDs, because transactions that have already been applied are automatically ignored. Before starting GTID-based replication, check for and clear all ignored server ID lists that have previously been set on the servers involved. The SHOW SLAVE STATUS statement, which can be
Replication with Global Transaction Identifiers

issued for individual channels, displays the list of ignored server IDs if there is one. If there is no list, the Replicate_Ignore_Server_Ids field is blank.

**GTID mode and mysqldump.** It is possible to import a dump made using mysqldump into a MySQL server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

**GTID mode and mysql_upgrade.** Prior to MySQL 8.0.16, when the server is running with global transaction identifiers (GTIDs) enabled (gtid_mode=ON), do not enable binary logging by mysql_upgrade (the --write-binlog option). As of MySQL 8.0.16, the server performs the entire MySQL upgrade procedure, but disables binary logging during the upgrade, so there is no issue.

### 17.1.3.7 Stored Function Examples to Manipulate GTIDs

MySQL includes some built-in (native) functions for use with GTID-based replication. These functions are as follows:

- **GTID_SUBSET(set1, set2)**
  Given two sets of global transaction identifiers `set1` and `set2`, returns true if all GTIDs in `set1` are also in `set2`. Returns false otherwise.

- **GTID_SUBTRACT(set1, set2)**
  Given two sets of global transaction identifiers `set1` and `set2`, returns only those GTIDs from `set1` that are not in `set2`.

- **WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])**
  Wait until the server has applied all of the transactions whose global transaction identifiers are contained in `gtid_set`. The optional timeout stops the function from waiting after the specified number of seconds have elapsed.

- **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][, channel])**
  Like WAIT_FOR_EXECUTED_GTID_SET(), but for a single started replication channel. Use WAIT_FOR_EXECUTED_GTID_SET() instead to ensure all channels are covered in all states.

For details of these functions, see Section 12.18, “Functions Used with Global Transaction Identifiers (GTIDs)".

You can define your own stored functions to work with GTIDs. For information on defining stored functions, see Chapter 24, Stored Programs and Views. The following examples show some useful stored functions that can be created based on the built-in GTID_SUBSET() and GTID_SUBTRACT() functions.

Note that in these stored functions, the delimiter command has been used to change the MySQL statement delimiter to a vertical bar, as follows:

```
mysql> delimiter |
```

All of these functions take string representations of GTID sets as arguments, so GTID sets must always be quoted when used with them.

This function returns nonzero (true) if two GTID sets are the same set, even if they are not formatted in the same way.

```
CREATE FUNCTION GTID_IS_EQUAL(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT) RETURNS INT
  RETURN GTID_SUBSET(gtid_set_1, gtid_set_2) AND GTID_SUBSET(gtid_set_2, gtid_set_1) |
```

This function returns nonzero (true) if two GTID sets are disjoint.

```
CREATE FUNCTION GTID_IS_DISJOINT(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT) RETURNS INT
  RETURN GTID_SUBSET(gtid_set_1, GTID_SUBTRACT(gtid_set_1, gtid_set_2)) | sum is the union of the two sets.
```
Replication with Global Transaction Identifiers

CREATE FUNCTION GTID_IS_DISJOINT_UNION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT, sum LONGTEXT)
RETURNS INT
  RETURN GTID_IS_EQUAL(GTID_SUBTRACT(sum, gtid_set_1), gtid_set_2) AND
  GTID_IS_EQUAL(GTID_SUBTRACT(sum, gtid_set_2), gtid_set_1)

This function returns a normalized form of the GTID set, in all uppercase, with no whitespace and no duplicates. The UUIDs are arranged in alphabetic order and intervals are arranged in numeric order.

CREATE FUNCTION GTID_NORMALIZE(g LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(g, '')

This function returns the union of two GTID sets.

CREATE FUNCTION GTID_UNION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_NORMALIZE(CONCAT(gtid_set_1, ',', gtid_set_2))

This function returns the intersection of two GTID sets.

CREATE FUNCTION GTID_INTERSECTION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gtid_set_1, GTID_SUBTRACT(gtid_set_1, gtid_set_2))

This function returns the symmetric difference between two GTID sets, that is, the GTIDs that exist in gtid_set_1 but not in gtid_set_2, and also the GTIDs that exist in gtid_set_2 but not in gtid_set_1.

CREATE FUNCTION GTID_SYMMETRIC_DIFFERENCE(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(CONCAT(gtid_set_1, ',', gtid_set_2), GTID_INTERSECTION(gtid_set_1, gtid_set_2))

This function removes from a GTID set all the GTIDs from a specified origin, and returns the remaining GTIDs, if any. The UUID is the identifier used by the server where the transaction originated, which is normally the server_uuid value.

CREATE FUNCTION GTID_SUBTRACT_UUID(gtid_set LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gtid_set, CONCAT(UUID, ':1-', (1 << 63) - 2))

This function reverses the previously listed function to return only those GTIDs from the GTID set that originate from the server with the specified identifier (UUID).

CREATE FUNCTION GTID_INTERSECTION_WITH_UUID(gtid_set LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gtid_set, GTID_SUBTRACT_UUID(gtid_set, uuid))

Example 17.1 Verifying that a replication slave is up to date

The built-in functions GTID_SUBSET and GTID_SUBTRACT can be used to check that a replication slave has applied at least every transaction that a master has applied.

To perform this check with GTID_SUBSET, execute the following statement on the slave:

```sql
SELECT GTID_SUBSET(master_gtid_executed, slave_gtid_executed)
```

If this returns 0 (false), some GTIDs in master_gtid_executed are not present in slave_gtid_executed, so the master has applied some transactions that the slave has not applied, and the slave is therefore not up to date.

To perform the check with GTID_SUBTRACT, execute the following statement on the slave:

```sql
SELECT GTID_SUBTRACT(master_gtid_executed, slave_gtid_executed)
```
This statement returns any GTIDs that are in \texttt{master_gtid_executed} but not in \texttt{slave_gtid_executed}. If any GTIDs are returned, the master has applied some transactions that the slave has not applied, and the slave is therefore not up to date.

**Example 17.2 Backup and restore scenario**

The stored functions \texttt{GTID\_IS\_EQUAL}, \texttt{GTID\_IS\_DISJOINT}, and \texttt{GTID\_IS\_DISJOINT\_UNION} could be used to verify backup and restore operations involving multiple databases and servers. In this example scenario, \texttt{server1} contains database \texttt{db1}, and \texttt{server2} contains database \texttt{db2}. The goal is to copy database \texttt{db2} to \texttt{server1}, and the result on \texttt{server1} should be the union of the two databases. The procedure used is to back up \texttt{server2} using \texttt{mysqlpump} or \texttt{mysqldump}, then restore this backup on \texttt{server1}.

Provided the backup program's option \texttt{--set-gtid-purged} was set to \texttt{ON} or the default of \texttt{AUTO}, the program's output contains a \texttt{SET @@GLOBAL.gtid_purged} statement that will add the \texttt{gtid_executed} set from \texttt{server2} to the \texttt{gtid_purged} set on \texttt{server1}. The \texttt{gtid_purged} set contains the GTIDs of all the transactions that have been committed on a server but do not exist in any binary log file on the server. When database \texttt{db2} is copied to \texttt{server1}, the GTIDs of the transactions committed on \texttt{server2}, which are not in the binary log files on \texttt{server1}, must be added to \texttt{server1}'s \texttt{gtid_purged} set to make the set complete.

The stored functions can be used to assist with the following steps in this scenario:

- **Use \texttt{GTID\_IS\_EQUAL}** to verify that the backup operation computed the correct GTID set for the \texttt{SET @@GLOBAL.gtid_purged} statement. On \texttt{server2}, extract that statement from the \texttt{mysqlpump} or \texttt{mysqldump} output, and store the GTID set into a local variable, such as \texttt{$gtid_purged_set}. Then execute the following statement:

  \begin{verbatim}
  server2> SELECT GTID\_IS\_EQUAL($gtid_purged_set, @@GLOBAL.gtid_executed);
  \end{verbatim}

  If the result is 1, the two GTID sets are equal, and the set has been computed correctly.

- **Use \texttt{GTID\_IS\_DISJOINT}** to verify that the GTID set in the \texttt{mysqlpump} or \texttt{mysqldump} output does not overlap with the \texttt{gtid_executed} set on \texttt{server1}. If there is any overlap, with identical GTIDs present on both servers for some reason, you will see errors when copying database \texttt{db2} to \texttt{server1}. To check, on \texttt{server1}, extract and store the \texttt{gtid_purged} set from the output into a local variable as above, then execute the following statement:

  \begin{verbatim}
  server1> SELECT GTID\_IS\_DISJOINT($gtid_purged_set, @@GLOBAL.gtid_executed);
  \end{verbatim}

  If the result is 1, there is no overlap between the two GTID sets, so no duplicate GTIDs are present.

- **Use \texttt{GTID\_IS\_DISJOINT\_UNION}** to verify that the restore operation resulted in the correct GTID state on \texttt{server1}. Before restoring the backup, on \texttt{server1}, obtain the existing \texttt{gtid_executed} set by executing the following statement:

  \begin{verbatim}
  server1> SELECT @@GLOBAL.gtid_executed;
  \end{verbatim}

  Store the result in a local variable \texttt{$original_gtid_executed}. Also store the \texttt{gtid_purged} set in a local variable as described above. When the backup from \texttt{server2} has been restored onto \texttt{server1}, execute the following statement to verify the GTID state:

  \begin{verbatim}
  server1> SELECT GTID\_IS\_DISJOINT\_UNION($original_gtid_executed,$gtid_purged_set,@@GLOBAL.gtid_executed);
  \end{verbatim}

  If the result is 1, the stored function has verified that the original \texttt{gtid_executed} set from \texttt{server1} \texttt{($original_gtid_executed)} and the \texttt{gtid_purged} set that was added from \texttt{server2}
($gtid_purged_set) have no overlap, and also that the updated gtid_executed set on server1 now consists of the previous gtid_executed set from server1 plus the gtid_purged set from server2, which is the desired result. Ensure that this check is carried out before any further transactions take place on server1, otherwise the new transactions in the gtid_executed set will cause it to fail.

**Example 17.3 Selecting the most up-to-date slave for manual failover**

The stored function `GTID_UNION` could be used to identify the most up-to-date replication slave from a set of slaves, in order to perform a manual failover operation after a replication master has stopped unexpectedly. If some of the slaves are experiencing replication lag, this stored function can be used to compute the most up-to-date slave without waiting for all the slaves to apply their existing relay logs, and therefore to minimize the failover time. The function can return the union of the gtid_executed set on each slave with the set of transactions received by the slave, which is recorded in the Performance Schema table `replication_connection_status`. You can compare these results to find which slave’s record of transactions is the most up-to-date, even if not all of the transactions have been committed yet.

On each replication slave, compute the complete record of transactions by issuing the following statement:

```sql
SELECT GTID_UNION(RECEIVED_TRANSACTION_SET, @@GLOBAL.gtid_executed)
FROM performance_schema.replication_connection_status
WHERE channel_name = 'name';
```

You can then compare the results from each slave to see which one has the most up-to-date record of transactions, and use this slave as the new replication master.

**Example 17.4 Checking for extraneous transactions on a replication slave**

The stored function `GTID_SUBTRACT_UUID` could be used to check whether a replication slave has received transactions that did not originate from its designated master or masters. If it has, there might be an issue with your replication setup, or with a proxy, router, or load balancer. This function works by removing from a GTID set all the GTIDs from a specified originating server, and returning the remaining GTIDs, if any.

For a replication slave with a single master, issue the following statement, giving the identifier of the originating replication master, which is normally the `server_uuid` value:

```sql
SELECT GTID_SUBTRACT_UUID(@@GLOBAL.gtid_executed, server_uuid_of_master);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from the designated master.

For a slave in a multi-master replication topology, repeat the function, for example:

```sql
SELECT GTID_SUBTRACT_UUID(GTID_SUBTRACT_UUID(@@GLOBAL.gtid_executed, server_uuid_of_master_1), server_uuid_of_master_2);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from any of the designated masters.

**Example 17.5 Verifying that a server in a replication topology is read-only**

The stored function `GTID_INTERSECTION_WITH_UUID` could be used to verify that a server has not originated any GTIDs and is in a read-only state. The function returns only those GTIDs from the GTID set that originate from the server with the specified identifier. If any of the transactions in the server’s gtid_executed set have the server’s own identifier, the server itself originated those transactions. You can issue the following statement on the server to check:

```sql
SELECT GTID_INTERSECTION_WITH_UUID(@@GLOBAL.gtid_executed, my_server_uuid);
```
Example 17.6 Validating an additional slave in a multi-master replication setup

The stored function `GTID_INTERSECTION_WITH_UUID` could be used to find out if a slave attached to a multi-master replication setup has applied all the transactions originating from one particular master. In this scenario, `master1` and `master2` are both masters and slaves and replicate to each other. `master2` also has its own replication slave. The replication slave will also receive and apply `master1`'s transactions if `master2` is configured with `log_slave_updates=ON`, but it will not do so if `master2` uses `log_slave_updates=OFF`. Whatever the case, we currently only want to find out if the replication slave is up to date with `master2`. In this situation, the stored function `GTID_INTERSECTION_WITH_UUID` can be used to identify the transactions that `master2` originated, discarding the transactions that `master2` has replicated from `master1`. The built-in function `GTID_SUBSET` can then be used to compare the result to the `gtid_executed` set on the slave. If the slave is up to date with `master2`, the `gtid_executed` set on the slave contains all the transactions in the intersection set (the transactions that originated from `master2`).

To carry out this check, store `master2`'s `gtid_executed` set, `master2`'s server UUID, and the slave's `gtid_executed` set, into client-side variables as follows:

```
$master2_gtid_executed :=
    master2> SELECT @@GLOBAL.gtid_executed;
$master2_server_uuid :=
    master2> SELECT @@GLOBAL.server_uuid;
$slave_gtid_executed :=
    slave> SELECT @@GLOBAL.gtid_executed;
```

Then use `GTID_INTERSECTION_WITH_UUID` and `GTID_SUBSET` with these variables as input, as follows:

```
SELECT GTID_SUBSET(GTID_INTERSECTION_WITH_UUID($master2_gtid_executed,
    $master2_server_uuid),
    $slave_gtid_executed);
```

The server identifier from `master2` (`$master2_server_uuid`) is used with `GTID_INTERSECTION_WITH_UUID` to identify and return only those GTIDs from `master2`'s `gtid_executed` set that originated on `master2`, omitting those that originated on `master1`. The resulting GTID set is then compared with the set of all executed GTIDs on the slave, using `GTID_SUBSET`. If this statement returns nonzero (true), all the identified GTIDs from `master2` (the first set input) are also in the slave's `gtid_executed` set (the second set input), meaning that the slave has replicated all the transactions that originated from `master2`.

17.1.4 MySQL Multi-Source Replication

This section describes MySQL Multi-Source Replication, which enables you to replicate from multiple immediate masters in parallel. This section describes multi-source replication, and how to configure, monitor and troubleshoot it.

17.1.4.1 MySQL Multi-Source Replication Overview

MySQL Multi-Source Replication enables a replication slave to receive transactions from multiple sources simultaneously. Multi-source replication can be used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. Multi-source replication does not implement any conflict detection or resolution when applying the transactions, and those tasks are left to the application if required. In a multi-source replication topology, a slave creates a replication channel for each master that it should receive transactions from. See Section 17.2.3, “Replication Channels”. The following sections describe how to set up multi-source replication.

17.1.4.2 Multi-Source Replication Tutorials
This section provides tutorials on how to configure masters and slaves for multi-source replication, and how to start, stop and reset multi-source slaves.

Configuring Multi-Source Replication

This section explains how to configure a multi-source replication topology, and provides details about configuring masters and slaves. Such a topology requires at least two masters and one slave configured.

Masters in a multi-source replication topology can be configured to use either global transaction identifier (GTID) based replication, or binary log position-based replication. See Section 17.1.3.4, “Setting Up Replication Using GTIDs” for how to configure a master using GTID based replication. See Section 17.1.2.1, “Setting the Replication Master Configuration” for how to configure a master using file position based replication.

Slaves in a multi-source replication topology require TABLE repositories for the master info log and relay log info log, which are the default in MySQL 8.0. Multi-source replication is not compatible with FILE based repositories, and the FILE setting for the --master-info-repository and --relay-log-info-repository options is now deprecated.

To modify an existing replication slave that is using a FILE repository for the slave status logs to use TABLE repositories, convert the existing replication repositories dynamically by running the following commands:

```
STOP SLAVE;
SET GLOBAL master_info_repository = 'TABLE';
SET GLOBAL relay_log_info_repository = 'TABLE';
```

Adding a GTID Based Master to a Multi-Source Replication Slave

This section assumes you have enabled GTID based transactions on the master using gtid_mode=ON, enabled a replication user, and ensured that the slave is using TABLE based replication repositories.

Use the CHANGE MASTER TO statement to add a new master to a channel by using a FOR CHANNEL clause. For more information on replication channels, see Section 17.2.3, “Replication Channels”

For example, to add a new master with the host name master1 using port 3451 to a channel called master-1:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', MASTER_AUTO_POSITION = 1 FOR CHANNEL 'master-1';
```

Multi-source replication is compatible with auto-positioning. See Section 13.4.2.1, “CHANGE MASTER TO Syntax” for more information.

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

Adding a Binary Log Based Master to a Multi-Source Replication Slave

This section assumes that binary logging is enabled on the master (which is the default), the slave is using TABLE based replication repositories (which is the default in MySQL 8.0), and that you have enabled a replication user and noted the current binary log position. You need to know the current MASTER_LOG_FILE and MASTER_LOG_POSITION. Use the CHANGE MASTER TO statement to add a new master to a channel by specifying a FOR CHANNEL clause. For example, to add a new master with the host name master1 using port 3451 to a channel called master-1:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', \ MASTER_LOG_FILE='master1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL 'master-1';
```
Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

**Starting Multi-Source Replication Slaves**

Once you have added all of the channels you want to use as replication masters, use a \texttt{START SLAVE thread_types} statement to start replication. When you have enabled multiple channels on a slave, you can choose to either start all channels, or select a specific channel to start.

- To start all currently configured replication channels:
  \begin{verbatim}
  START SLAVE thread_types;
  \end{verbatim}

- To start only a named channel, use a \texttt{FOR CHANNEL channel} clause:
  \begin{verbatim}
  START SLAVE thread_types FOR CHANNEL channel;
  \end{verbatim}

Use the \texttt{thread_types} option to choose specific threads you want the above statements to start on the slave. See Section 13.4.2.6, “START SLAVE Syntax” for more information.

**Stopping Multi-Source Replication Slaves**

The \texttt{STOP SLAVE} statement can be used to stop a multi-source replication slave. By default, if you use the \texttt{STOP SLAVE} statement on a multi-source replication slave all channels are stopped. Optionally, use the \texttt{FOR CHANNEL channel} clause to stop only a specific channel.

- To stop all currently configured replication channels:
  \begin{verbatim}
  STOP SLAVE thread_types;
  \end{verbatim}

- To stop only a named channel, use a \texttt{FOR CHANNEL channel} clause:
  \begin{verbatim}
  STOP SLAVE thread_types FOR CHANNEL channel;
  \end{verbatim}

Use the \texttt{thread_types} option to choose specific threads you want the above statements to stop on the slave. See Section 13.4.2.7, “STOP SLAVE Syntax” for more information.

**Resetting Multi-Source Replication Slaves**

The \texttt{RESET SLAVE} statement can be used to reset a multi-source replication slave. By default, if you use the \texttt{RESET SLAVE} statement on a multi-source replication slave all channels are reset. Optionally, use the \texttt{FOR CHANNEL channel} clause to reset only a specific channel.

- To reset all currently configured replication channels:
  \begin{verbatim}
  RESET SLAVE;
  \end{verbatim}

- To reset only a named channel, use a \texttt{FOR CHANNEL channel} clause:
  \begin{verbatim}
  RESET SLAVE FOR CHANNEL channel;
  \end{verbatim}

See Section 13.4.2.4, “RESET SLAVE Syntax” for more information.

**17.1.4.3 Multi-Source Replication Monitoring**
To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is Channel_Name. This enables you to write complex queries based on Channel_Name as a key. See Section 26.12.11, “Performance Schema Replication Tables”.

- Using SHOW SLAVE STATUS FOR CHANNEL channel. By default, if the FOR CHANNEL channel clause is not used, this statement shows the slave status for all channels with one row per channel. The identifier Channel_name is added as a column in the result set. If a FOR CHANNEL channel clause is provided, the results show the status of only the named replication channel.

**Note**

The SHOW VARIABLES statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a SHOW VARIABLES statement in a topology with multiple channels shows the status of only the default channel.

### Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```sql
mysql> SELECT * FROM replication_connection_status\G;
*************************** 1. row ***************************
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
*************************** 2. row ***************************
CHANNEL_NAME: master2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the CHANNEL_NAME field they are called master1 and master2.

The addition of the CHANNEL_NAME field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a WHERE CHANNEL_NAME=channel clause:
-changing replication modes on online servers

17.1.4 Multi-Source Replication Error Messages

Error codes and messages provide information about errors encountered in a multi-source replication topology. These error codes and messages are only emitted when multi-source replication is enabled, and provide information related to the channel that generated the error. For example:

- Slave is already running
- Slave is already stopped

The server log messages have also been changed to indicate which channel the log messages relate to.

17.1.5 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline.

17.1.5.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server, it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form UUID:NUMBER.
- Anonymous transactions do not have a GTID assigned, and MySQL ensures that every anonymous transaction in a log is always preceded by an Anonymous_gtid_log_event. Anonymous transactions can only be addressed using either the GTID or using the file name and position.

When using GTIDs, you can take advantage of auto-positioning and automatic fail-over, as well as use WAIT_FOR_EXECUTED_GTID_SET() and session_track_gtids, and monitor replicated transactions instead of using slave slave skip counter.

Similarly, the WHERE CHANNEL_NAME=channel1 clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see Section 26.12.11, "Performance Schema Replication Tables."
Transactions in a relay log that was received from a master running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the slave's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set from a top-level statement by an account that has privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”. In MySQL 5.6 and earlier, both of these variables could only be configured using the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. When `gtid_mode=OFF_PERMISSIVE` then new transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then new transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a master with `gtid_mode=ON` could be replicating to a slave with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- OFF
- OFF_PERMISSIVE
- ON_PERMISSIVE
- ON

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

The fields related to GTIDs display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the Performance Schema `replication_applier_status_by_worker` table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a master using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see Section 17.1.5.2, “Enabling GTID Transactions Online”.

The valid combinations of `gtid_mode` and auto-positioning on master and slave are shown in the following table, where the master's `gtid_mode` is shown on the horizontal and the slave's `gtid_mode` is on the vertical. The meaning of each entry is as follows:
Changing Replication Modes on Online Servers

- **Y**: the `gtid_mode` of master and slave is compatible
- **N**: the `gtid_mode` of master and slave is not compatible
- *****: auto-positioning can be used with this combination

**Table 17.1 Valid Combinations of Master and Slave gtid_mode**

<table>
<thead>
<tr>
<th>gtid_mode</th>
<th>Master OFF</th>
<th>Master OFF_PERMISSIVE</th>
<th>Master ON_PERMISSIVE</th>
<th>Master ON</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slave OFF</td>
<td>Y</td>
<td>Y</td>
<td>N</td>
<td>N</td>
</tr>
<tr>
<td>Slave OFF_PERMISSIVE</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>Y*</td>
</tr>
<tr>
<td>Slave ON_PERMISSIVE</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>Y*</td>
</tr>
<tr>
<td>Slave ON</td>
<td>N</td>
<td>N</td>
<td>Y</td>
<td>Y*</td>
</tr>
</tbody>
</table>

The currently selected `gtid_mode` also impacts on the `gtid_next` variable. The following table shows the behavior of the server for the different values of `gtid_mode` and `gtid_next`. The meaning of each entry is as follows:

- **ANONYMOUS**: generate an anonymous transaction.
- **Error**: generate an error and fail to execute `SET GTID_NEXT`.
- **UUID:NUMBER**: generate a GTID with the specified UUID:NUMBER.
- **New GTID**: generate a GTID with an automatically generated number.

**Table 17.2 Valid Combinations of gtid_mode and gtid_next**

<table>
<thead>
<tr>
<th>gtid_mode OFF AUTOMATIC</th>
<th>gtid_next AUTOMATIC binary log on</th>
<th>gtid_next AUTOMATIC binary log off</th>
<th>gtid_next ANONYMOUS</th>
<th>gtid_next UUID:NUMBER</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>Error</td>
</tr>
<tr>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>UUID:NUMBER</td>
</tr>
<tr>
<td>New GTID</td>
<td>New GTID</td>
<td>ANONYMOUS</td>
<td>ANONYMOUS</td>
<td>UUID:NUMBER</td>
</tr>
<tr>
<td>New GTID</td>
<td>New GTID</td>
<td>ANONYMOUS</td>
<td>Error</td>
<td>UUID:NUMBER</td>
</tr>
</tbody>
</table>

When the binary log is off and `gtid_next` is set to `AUTOMATIC`, then no GTID is generated. This is consistent with the behavior of previous versions.

### 17.1.5.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- **All** servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless **all** servers which are in the topology are using this version.
Changing Replication Modes on Online Servers

- All servers have `gtid_mode` set to the default value `OFF`.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of Section 17.1.5.3, “Disabling GTID Transactions Online”, the online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

Note

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

   ```sql
   SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
   ```

   Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

   Important

   This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

   ```sql
   SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
   ```

3. On each server, execute:

   ```sql
   SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
   ```

   It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

   ```sql
   SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
   ```

   It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero.

   This can be checked using:

   ```sql
   SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
   ```

   Note

   On a replication slave, it is theoretically possible that this shows zero and then nonzero again. This is not a problem, it suffices that it shows zero once.

6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

   See Section 17.1.5.4, “Verifying Replication of Anonymous Transactions” for one method of checking that all anonymous transactions have replicated to all servers.
7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

**Important**

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

8. On each server, execute:

   ```sql
   SET @@GLOBAL.GTID_MODE = ON;
   ```

9. On each server, add `gtid-mode=ON` to `my.cnf`.

You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each slave. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

   ```sql
   STOP SLAVE [FOR CHANNEL 'channel'];
   CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
   START SLAVE [FOR CHANNEL 'channel'];
   ```

### 17.1.5.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless all servers which are in the topology are using this version.
- All servers have `gtid_mode` set to `ON`.

1. Execute the following on each slave, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL channel` clause:

   ```sql
   STOP SLAVE [FOR CHANNEL 'channel'];
   CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \n   MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
   START SLAVE [FOR CHANNEL 'channel'];
   ```

2. On each server, execute:
Changing Replication Modes on Online Servers

```sql
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

3. On each server, execute:

```sql
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

4. On each server, wait until the variable `@@GLOBAL.GTID_OWNED` is equal to the empty string. This can be checked using:

```sql
SELECT @@GLOBAL.GTID_OWNED;
```

On a replication slave, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

5. Wait for all transactions that currently exist in any binary log to replicate to all slaves. See Section 17.1.5.4, “Verifying Replication of Anonymous Transactions” for one method of checking that all anonymous transactions have replicated to all servers.

6. If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

**Important**

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

7. On each server, execute:

```sql
SET @@GLOBAL.GTID_MODE = OFF;
```

8. On each server, set `gtid-mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. After setting it, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

### 17.1.5.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the slave never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.
A safer method in the sense that it does not depend on timing: if you only have a master with one or more slaves, do the following:

1. On the master, execute:

   ```sql
   SHOW MASTER STATUS;
   ```

   Note down the values in the `File` and `Position` column.

2. On every slave, use the file and position information from the master to execute:

   ```sql
   SELECT MASTER_POS_WAIT(file, position);
   ```

If you have a master and multiple levels of slaves, or in other words you have slaves of slaves, repeat step 2 on each level, starting from the master, then all the direct slaves, then all the slaves of slaves, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each master-slave connection, until you have completed the full circle. Repeat the whole process so that you do the full circle twice.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

### 17.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id` option.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--server-id=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>server_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (<code>&gt;= 8.0.3</code>)</td>
<td>1</td>
</tr>
<tr>
<td>Default Value (<code>&lt;= 8.0.2</code>)</td>
<td>0</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Specifies the server ID. The `server_id` system variable is set to 1 by default. The server can be started with this default ID, but when binary logging is enabled, an informational message is issued if you did not specify a server ID explicitly using the `--server-id` option.

For servers that are used in a replication topology, you must specify a unique server ID for each replication server, in the range from 1 to $2^{32} - 1$. "Unique" means that each ID must be different from every other ID in use by any other replication master or slave. For additional information, see Section 17.1.6.2, “Replication Master Options and Variables”, and Section 17.1.6.3, “Replication Slave Options and Variables”.

If the server ID is set to 0, binary logging takes place, but a master with a server ID of 0 refuses any connections from slaves, and a slave with a server ID of 0 refuses to connect to a master. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replication slave.

For more information, see Section 17.1.2.2, “Setting the Replication Slave Configuration”.

**server_uuid**

The MySQL server generates a true UUID in addition to the default or user-supplied server ID set in the `server_id` system variable. This is available as the global, read-only variable `server_uuid`.

**Note**

The presence of the `server_uuid` system variable does not change the requirement for setting a unique `--server-id` for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>server_uuid</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).

2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```
Important

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, masters and slaves know each other's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

Note

Issuing a `STOP SLAVE` or `RESET SLAVE` statement does not reset the master's UUID as used on the slave.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` exists.
- The master's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

17.1.6.1 Replication and Binary Logging Option and Variable Reference

The following two lists provide basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

The command-line options and system variables in the following list relate to replication masters and replication slaves. Section 17.1.6.2, “Replication Master Options and Variables”, provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see Section 17.1.6.3, “Replication Slave Options and Variables”.

- `abort-slave-event-count`: Option used by mysql-test for debugging and testing of replication
- `binlog_expire_logs_seconds`: Purge binary logs after this many seconds
- `binlog_gtid_simple_recovery`: Controls how binary logs are iterated during GTID recovery
- `Com_change_master`: Count of CHANGE MASTER TO statements
- `Com_show_master_status`: Count of SHOW MASTER STATUS statements
- `Com_show_slave_hosts`: Count of SHOW SLAVE HOSTS statements
- `Com_show_slave_status`: Count of SHOW SLAVE STATUS statements
- `Com_slave_start`: Count of START SLAVE statements
- `Com_slave_stop`: Count of STOP SLAVE statements
- `disconnect-slave-event-count`: Option used by mysql-test for debugging and testing of replication
- `enforce-gtid-consistency`: Prevents execution of statements that cannot be logged in a transactionally safe manner
Replication and Binary Logging Options and Variables

- **enforce_gtid_consistency**: Prevents execution of statements that cannot be logged in a transactionally safe manner

- **executed-gtids-compression-period**: Deprecated and will be removed in a future version; use the renamed gtid-executed-compression-period instead

- **executed_gtids_compression_period**: Deprecated and will be removed in a future version; use the renamed gtid_executed_compression_period instead

- **expire_logs_days**: Purge binary logs after this many days

- **gtid-executed-compression-period**: Compress gtid_executed table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled.

- **gtid_mode**: Controls whether GTID based logging is enabled and what type of transactions the logs can contain

- **gtid_executed**: Global: All GTIDs in the binary log (global) or current transaction (session). Read-only.

- **gtid_executed_compression_period**: Compress gtid_executed table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled.

- **gtid_next**: Specifies the GTID for the next statement to execute; see documentation for details

- **gtid_owned**: The set of GTIDs owned by this client (session), or by all clients, together with the thread ID of the owner (global). Read-only.

- **gtid_purged**: The set of all GTIDs that have been purged from the binary log

- **init_slave**: Statements that are executed when a slave connects to a master

- **log-bin-trust-function-creators**: If equal to 0 (the default), then when --log-bin is used, creation of a stored function is allowed only to users having the SUPER privilege and only if the function created does not break binary logging

- **log-slave-updates**: Tells the slave to log the updates performed by its SQL thread to its own binary log

- **log_builtin_as_identified_by_password**: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion

- **log_slave_updates**: Whether the slave should log the updates performed by its SQL thread to its own binary log. Read-only; set using the --log-slave-updates server option.

- **log_statements_unsafe_for_binlog**: Disables error 1592 warnings being written to the error log

- **master-info-file**: The location and name of the file that remembers the master and where the I/O replication thread is in the master's binary logs

- **master-info-repository**: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table

- **master-retry-count**: Number of tries the slave makes to connect to the master before giving up
• **master_info_repository**: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table

• **max_relay_log_size**: If nonzero, relay log is rotated automatically when its size exceeds this value. If zero, size at which rotation occurs is determined by the value of max_binlog_size.

• **original_commit_timestamp**: The time when a transaction was committed on the original master

• **relay-log**: The location and base name to use for relay logs

• **relay-log-index**: The location and name to use for the file that keeps a list of the last relay logs

• **relay-log-info-file**: The location and name of the file that remembers where the SQL replication thread is in the relay logs

• **relay-log-info-repository**: Whether to write the replication SQL thread's location in the relay logs to a file or a table

• **relay-log-recovery**: Enables automatic recovery of relay log files from master at startup

• **relay_log_basename**: Complete path to relay log, including filename

• **relay_log_index**: The name of the relay log index file

• **relay_log_info_file**: The name of the file in which the slave records information about the relay logs

• **relay_log_info_repository**: Whether to write the replication SQL thread's location in the relay logs to a file or a table

• **relay_log_purge**: Determines whether relay logs are purged

• **relay_log_recovery**: Whether automatic recovery of relay log files from master at startup is enabled; must be enabled for a crash-safe slave

• **relay_log_space_limit**: Maximum space to use for all relay logs

• **replicate-do-db**: Tells the slave SQL thread to restrict replication to the specified database

• **replicate-do-table**: Tells the slave SQL thread to restrict replication to the specified table

• **replicate-ignore-db**: Tells the slave SQL thread not to replicate to the specified database

• **replicate-ignore-table**: Tells the slave SQL thread not to replicate to the specified table

• **replicate-rewrite-db**: Updates to a database with a different name than the original

• **replicate-same-server-id**: In replication, if enabled, do not skip events having our server id

• **replicate-wild-do-table**: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern

• **replicate-wild-ignore-table**: Tells the slave thread not to replicate to the tables that match the given wildcard pattern

• **report-host**: Host name or IP of the slave to be reported to the master during slave registration

• **report-password**: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.

• **report-port**: Port for connecting to slave reported to the master during slave registration
• **report-user**: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account.

• **Rpl_semi_sync_master_clients**: Number of semisynchronous slaves

• **rpl_semi_sync_master_enabled**: Whether semisynchronous replication is enabled on the master

• **Rpl_semi_sync_master_net_avg_wait_time**: The average time the master waited for a slave reply

• **Rpl_semi_sync_master_net_wait_time**: The total time the master waited for slave replies

• **Rpl_semi_sync_master_net_waits**: The total number of times the master waited for slave replies

• **Rpl_semi_sync_master_no_times**: Number of times the master turned off semisynchronous replication

• **Rpl_semi_sync_master_no_tx**: Number of commits not acknowledged successfully

• **Rpl_semi_sync_master_status**: Whether semisynchronous replication is operational on the master

• **Rpl_semi_sync_master_timefunc_failures**: Number of times the master failed when calling time functions

• **rpl_semi_sync_master_timeout**: Number of milliseconds to wait for slave acknowledgment

• **rpl_semi_sync_master_trace_level**: The semisynchronous replication debug trace level on the master

• **Rpl_semi_sync_master_tx_avg_wait_time**: The average time the master waited for each transaction

• **Rpl_semi_sync_master_tx_wait_time**: The total time the master waited for transactions

• **Rpl_semi_sync_master_tx_waits**: The total number of times the master waited for transactions

• **rpl_semi_sync_master_wait_for_slave_count**: How many slave acknowledgments the master must receive per transaction before proceeding

• **rpl_semi_sync_master_wait_no_slave**: Whether master waits for timeout even with no slaves

• **rpl_semi_sync_master_wait_point**: The wait point for slave transaction receipt acknowledgment

• **Rpl_semi_sync_master_wait_sessions**: Number of sessions currently waiting for slave replies

• **Rpl_semi_sync_master_yes_tx**: Number of commits acknowledged successfully

• **rpl_semi_sync_slave_enabled**: Whether semisynchronous replication is enabled on slave

• **Rpl_semi_sync_slave_status**: Whether semisynchronous replication is operational on slave

• **rpl_semi_sync_slave_trace_level**: The semisynchronous replication debug trace level on the slave

• **rpl_read_size**: Set the minimum amount of data in bytes that is read from the binary log files and relay log files

• **rpl_stop_slave_timeout**: Set the number of seconds that STOP SLAVE waits before timing out
Replication and Binary Logging Options and Variables

- **server_uuid**: The server's globally unique ID, automatically (re)generated at server start
- **show-slave-auth-info**: Show user name and password in SHOW SLAVE HOSTS on this master
- **simplified_binlog_gtid_recovery**: Controls how binary logs are iterated during GTID recovery
- **skip-slave-start**: If set, slave is not autostarted
- **slave-checkpoint-group**: Maximum number of transactions processed by a multithreaded slave before a checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- **slave-checkpoint-period**: Update progress status of multithreaded slave and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- **slave-load-tmpdir**: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement
- **slave-max-allowed-packet**: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet
- **slave_net_timeout**: Number of seconds to wait for more data from a master/slave connection before aborting the read
- **slave-parallel-type**: Tells the slave to use timestamp information (LOGICAL_CLOCK) or database partitioning (DATABASE) to parallelize transactions. The default is LOGICAL_CLOCK.
- **slave-parallel-workers**: Number of applier threads for executing replication transactions in parallel. The default is 4 applier threads. Set to 0 to disable slave multithreading. Not supported by MySQL Cluster.
- **slave-pending-jobs-size-max**: Maximum size of slave worker queues holding events not yet applied
- **slave_rows_search_algorithms**: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN
- **slave_skip_errors**: Tells the slave thread to continue replication when a query returns an error from the provided list
- **slave_checkpoint_group**: Maximum number of transactions processed by a multithreaded slave before a checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- **slave_checkpoint_period**: Update progress status of multithreaded slave and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- **slave_compressed_protocol**: Use compression on master/slave protocol
- **slave_exec_mode**: Allows for switching the slave thread between IDENTITY mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for NDB Cluster, where IDENTITY is always used
- **Slave_heartbeat_period**: The slave's replication heartbeat interval, in seconds
- **Slave_last_heartbeat**: Shows when the latest heartbeat signal was received, in TIMESTAMP format
- **slave_max_allowed_packet**: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet
- **Slave_open_tmp_tables**: Number of temporary tables that the slave SQL thread currently has open
Replication and Binary Logging Options and Variables

- **slave_parallel_type**: Tells the slave to use timestamp information (LOGICAL_CLOCK) or database partitioning (DATABASE) to parallelize transactions.

- **slave_parallel_workers**: Number of applier threads for executing replication transactions in parallel. A value of 0 disables slave multithreading. Not supported by MySQL Cluster.

- **slave_pending_jobs_size_max**: Maximum size of slave worker queues holding events not yet applied.

- **slave_preserve_commit_order**: Ensures that all commits by slave workers happen in the same order as on the master to maintain consistency when using parallel applier threads.

- **Slave_received_heartbeats**: Number of heartbeats received by a replication slave since previous reset.

- **Slave_retried_transactions**: The total number of times since startup that the replication slave SQL thread has retried transactions.

- **slave_rows_search_algorithms**: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN.

- **Slave_rows_last_search_algorithm_used**: Search algorithm most recently used by this slave to locate rows for row-based replication (index, table, or hash scan).

- **Slave_running**: The state of this server as a replication slave (slave I/O thread status).

- **slave_transaction_retries**: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping.

- **slave_type_conversions**: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave.

- **sql_log_bin**: Controls binary logging for the current session.

- **sql_slave_skip_counter**: Number of events from the master that a slave server should skip. Not compatible with GTID replication.

- **sync_binlog**: Synchronously flush binary log to disk after every #th event.

- **sync_master_info**: Synchronize master.info to disk after every #th event.

- **sync_relay_log**: Synchronize relay log to disk after every #th event.

- **sync_relay_log_info**: Synchronize relay.info file to disk after every #th event.

- **transaction_write_set_extraction**: Defines the algorithm used to hash the writes extracted during a transaction.

The command-line options and system variables in the following list relate to the binary log. Section 17.1.6.4, “Binary Logging Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, “The Binary Log”.

- **binlog-checksum**: Enable/disable binary log checksums.

- **binlog-do-db**: Limits binary logging to specific databases.

- **binlog_format**: Specifies the format of the binary log.
• **binlog-ignore-db**: Tells the master that updates to the given database should not be logged to the binary log.

• **binlog-row-event-max-size**: Binary log max event size.

• **binlog-rows-query-log-events**: Enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6 slaves/readers.

• **Binlog_cache_disk_use**: Number of transactions that used a temporary file instead of the binary log cache.

• **binlog_cache_size**: Size of the cache to hold the SQL statements for the binary log during a transaction.

• **Binlog_cache_use**: Number of transactions that used the temporary binary log cache.

• **binlog_checksum**: Enable/disable binary log checksums.

• **binlog_direct_non_transactional_updates**: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.

• **binlog_error_action**: Controls what happens when the server cannot write to the binary log.

• **binlog_group_commit_sync_delay**: Sets the number of microseconds to wait before synchronizing transactions to disk.

• **binlog_group_commit_sync_no_delay_count**: Sets the maximum number of transactions to wait for before aborting the current delay specified by `binlog_group_commit_sync_delay`.

• **binlog_max_flush_queue_time**: How long to read transactions before flushing to binary log.

• **binlog_order_commits**: Whether to commit in same order as writes to binary log.

• **binlog_row_image**: Use full or minimal images when logging row changes.

• **binlog_row_metadata**: Configures the amount of table related metadata binary logged when using row-based logging.

• **binlog_row_value_options**: Enables binary logging of partial JSON updates for row-based replication.

• **binlog_rows_query_log_events**: When TRUE, enables logging of rows query log events in row-based logging mode. FALSE by default. Do not enable when producing logs for pre-5.6 replication slaves or other readers.

• **Binlog_stmt_cache_disk_use**: Number of nontransactional statements that used a temporary file instead of the binary log statement cache.

• **binlog_stmt_cache_size**: Size of the cache to hold nontransactional statements for the binary log during a transaction.

• **Binlog_stmt_cache_use**: Number of statements that used the temporary binary log statement cache.

• **binlog_transaction_dependency_tracking**: Source of dependency information (commit timestamps or transaction write sets) from which to assess which transactions can be executed in parallel by slave’s multithreaded applier.

• **binlog_transaction_dependency_history_size**: Number of row hashes kept for looking up transactions that last updated some row.

• **Com_show_binlog_events**: Count of SHOW BINLOG EVENTS statements.
Replication and Binary Logging Options and Variables

- **Com_show_binlogs**: Count of SHOW BINLOGS statements
- **log-bin-use-v1-row-events**: Use version 1 binary log row events
- **log_bin_basename**: Path and base name for binary log files
- **log_bin_use_v1_row_events**: Shows whether server is using version 1 binary log row events
- **master-verify-checksum**: Cause master to examine checksums when reading from the binary log
- **master_verify_checksum**: Cause master to read checksums from binary log
- **max-binlog-dump-events**: Option used by mysql-test for debugging and testing of replication
- **max_binlog_cache_size**: Can be used to restrict the total size used to cache a multi-statement transaction
- **max_binlog_size**: Binary log will be rotated automatically when size exceeds this value
- **max_binlog_stmt_cache_size**: Can be used to restrict the total size used to cache all nontransactional statements during a transaction
- **slave-sql-verify-checksum**: Cause slave to examine checksums when reading from the relay log
- **slave_sql_verify_checksum**: Cause slave to examine checksums when reading from relay log
- **sporadic-binlog-dump-fail**: Option used by mysql-test for debugging and testing of replication

For a listing of all command-line options, system and status variables used with **mysqld**, see Section 5.1.4, "Server Option, System Variable, and Status Variable Reference".

### 17.1.6.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using **SET**.

On the master and each slave, you must use the **server-id** option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: **server-id=3**.

For options used on the master for controlling binary logging, see Section 17.1.6.4, “Binary Logging Options and Variables”.

#### Startup Options for Replication Masters

The following list describes startup options for controlling replication master servers. Replication-related system variables are discussed later in this section.

- **--show-slave-auth-info**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--show-slave-auth-info</strong></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><strong>FALSE</strong></td>
</tr>
</tbody>
</table>

Display slave user names and passwords in the output of **SHOW SLAVE HOSTS** on the master server for slaves started with the **--report-user** and **--report-password** options.
System Variables Used on Replication Masters

The following system variables are used for or by replication masters:

- `auto_increment_increment`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>auto_increment_increment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

Note

`auto_increment_increment` is also supported for use with NDB tables.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

  ```
  mysql> SHOW VARIABLES LIKE 'auto_in%';
  +--------------------------+-------+
  | Variable_name            | Value |
  +--------------------------+-------+
  | auto_increment_increment | 1     |
  | auto_increment_offset    | 1     |
  +--------------------------+-------+
  2 rows in set (0.00 sec)
  mysql> CREATE TABLE autoinc1
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
  Query OK, 0 rows affected (0.04 sec)
  mysql> SET @@auto_increment_increment=10;
  Query OK, 0 rows affected (0.00 sec)
  ```
Replication and Binary Logging Options and Variables

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
|--------------------------+-------|
| auto_increment_increment | 10    |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
<table>
<thead>
<tr>
<th>col</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>11</td>
</tr>
<tr>
<td>21</td>
</tr>
<tr>
<td>31</td>
</tr>
</tbody>
</table>
+-----+
4 rows in set (0.00 sec)

- **auto_increment_offset** determines the starting point for the AUTO_INCREMENT column value.
  
  Consider the following, assuming that these statements are executed during the same session as the example given in the description for **auto_increment_increment**:

```sql
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
|--------------------------+-------|
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
<table>
<thead>
<tr>
<th>col</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
</tr>
<tr>
<td>15</td>
</tr>
<tr>
<td>25</td>
</tr>
<tr>
<td>35</td>
</tr>
</tbody>
</table>
+-----+
4 rows in set (0.02 sec)
```

When the value of **auto_increment_offset** is greater than that of **auto_increment_increment**, the value of **auto_increment_offset** is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an AUTO_INCREMENT column, the results may seem counterintuitive because the series of
**AUTO_INCREMENT** values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the **AUTO_INCREMENT** column. The series is calculated like this:

\[
\text{auto_increment_offset} + N \times \text{auto_increment_increment}
\]

where \( N \) is a positive integer value in the series \([1, 2, 3, \ldots]\). For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
```

```sql
mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
```

```sql
mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
| 35  |
| 45  |
| 55  |
| 65  |
+-----+
```

The values shown for **auto_increment_increment** and **auto_increment_offset** generate the series \(5 + N \times 10\), that is, \([5, 15, 25, 35, 45, \ldots]\). The highest value present in the **col** column prior to the **INSERT** is 31, and the next available value in the **AUTO_INCREMENT** series is 35, so the inserted values for **col** begin at that point and the results are as shown for the **SELECT** query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all **AUTO_INCREMENT** columns in all tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until **mysqld** is restarted. If the local value is set, the new value affects **AUTO_INCREMENT** columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of **auto_increment_increment** is 1. See Section 17.4.1.1, "Replication and **AUTO_INCREMENT**".
• **auto_increment_offset**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>auto_increment_offset</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

This variable has a default value of 1. For more information, see the description for `auto_increment_increment`.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

**Note**

`auto_increment_offset` is also supported for use with NDB tables.

• **immediate_server_version**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>immediate_server_version</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

For internal use by replication. This session system variable holds the MySQL Server release number of the server that is the immediate master in a replication topology (for example, 80014 for a MySQL 8.0.14 server instance). If this immediate server is at a release that does not support the session system variable, the value of the variable is set to 0 (UNKNOWN_SERVER_VERSION).

The value of the variable is replicated from a master to a slave. With this information the slave can correctly process data originating from a master at an older release, by recognizing where syntax changes or semantic changes have occurred between the releases involved and handling these appropriately. The information can also be used in a Group Replication environment where one or more members of the replication group is at a newer release than the others. The value of the variable can be viewed in the binary log for each transaction (as part of the Gtid_log_event, or Anonymous_gtid_log_event if GTIDs are not in use on the server), and could be helpful in debugging cross-version replication issues.
Setting the session value of this system variable is a restricted operation. See Section 5.1.9.1, “System Variable Privileges”. However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

- **original_server_version**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>original_server_version</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

For internal use by replication. This session system variable holds the MySQL Server release number of the server where a transaction was originally committed (for example, 80014 for a MySQL 8.0.14 server instance). If this original server is at a release that does not support the session system variable, the value of the variable is set to 0 (UNKNOWN_SERVER_VERSION). Note that when a release number is set by the original server, the value of the variable is reset to 0 if the immediate server or any other intervening server in the replication topology does not support the session system variable, and so does not replicate its value.

The value of the variable is set and used in the same ways as for the `immediate_server_version` system variable. If the value of the variable is the same as that for the `immediate_server_version` system variable, only the latter is recorded in the binary log, with an indicator that the original server version is the same.

In a Group Replication environment, view change log events, which are special transactions queued by each group member when a new member joins the group, are tagged with the server version of the group member queuing the transaction. This ensures that the server version of the original donor is known to the joining member. Because the view change log events queued for a particular view change have the same GTID on all members, for this case only, instances of the same GTID might have a different original server version.

Setting the session value of this system variable is a restricted operation. See Section 5.1.9.1, “System Variable Privileges”. However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

- **rpl_semi_sync_master_enabled**

<table>
<thead>
<tr>
<th>Property</th>

<td>OFF</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to **ON** or **OFF** (or 1 or 0), respectively. The default is **OFF**.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>rpl_semi_sync_master_timeout</td>

<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
</tbody>
</table>

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_trace_level**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>rpl_semi_sync_master_trace_level</td>

<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
</tbody>
</table>

The semisynchronous replication debug trace level on the master. Four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of slave acknowledgments the master must receive per transaction before proceeding. By default `rpl_semi_sync_master_wait_for_slave_count` is 1, meaning that semisynchronous replication proceeds after receiving a single slave acknowledgment. Performance is best for small values of this variable.

For example, if `rpl_semi_sync_master_wait_for_slave_count` is 2, then 2 slaves must acknowledge receipt of the transaction before the timeout period configured by `rpl_semi_sync_master_timeout` for semisynchronous replication to proceed. If less slaves acknowledge receipt of the transaction during the timeout period, the master reverts to normal replication.

**Note**
This behavior also depends on `rpl_semi_sync_master_wait_no_slave`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_master_wait_no_slave</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Controls whether the master waits for the timeout period configured by `rpl_semi_sync_master_timeout` to expire, even if the slave count drops to less than the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count` during the timeout period.

When the value of `rpl_semi_sync_master_wait_no_slave` is ON (the default), it is permissible for the slave count to drop to less than `rpl_semi_sync_master_wait_for_slave_count` during the timeout period. As long as enough slaves acknowledge the transaction before the timeout period expires, semisynchronous replication continues.

When the value of `rpl_semi_sync_master_wait_no_slave` is OFF, if the slave count drops to less than the number configured in `rpl_semi_sync_master_wait_for_slave_count` at any time during the timeout period configured by `rpl_semi_sync_master_timeout`, the master reverts to normal replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.
• **rpl_semi_sync_master_wait_point**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td>rpl_semi_sync_master_wait_point</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>AFTER_SYNC</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>AFTER_SYNC, AFTER_COMMIT</td>
</tr>
</tbody>
</table>

This variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- **AFTER_SYNC** (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.

- **AFTER_COMMIT**: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- **With AFTER_SYNC**, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

  In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date. Note, however, that the master cannot be restarted in this scenario and must be discarded, because its binary log might contain uncommitted transactions that would cause a conflict with the slave when externalized after binary log recovery.

- **With AFTER_COMMIT**, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

  If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

This variable is available only if the master-side semisynchronous replication plugin is installed.

With the addition of **rpl_semi_sync_master_wait_point** in MySQL 5.7, a version compatibility constraint was created because it increments the semisynchronous interface version: Servers for MySQL 5.7 and higher do not work with semisynchronous replication plugins from older versions, nor do servers from older versions work with semisynchronous replication plugins for MySQL 5.7 and higher.
17.1.6.3 Replication Slave Options and Variables

This section explains the server options and system variables that apply to slave replication servers and
contains the following:

- **Startup Options for Replication Slaves**
- **Options for Logging Slave Status to Tables**
- **System Variables Used on Replication Slaves**

Specify the options either on the command line or in an option file. Many of the options can be set while the
server is running by using the `CHANGE MASTER TO` statement. Specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique
replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every
other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

### Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can
be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables
are discussed later in this section.

- **--log-slave-updates**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-slave-updates</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_slave_updates</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.3)</td>
<td><code>ON</code></td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.2)</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

This option makes a slave write updates that are received from a master server and performed by the
slave’s SQL thread to the slave’s own binary log. Binary logging, which is controlled by the `--log-bin`
option and is enabled by default, must also be enabled on the slave for updates to be logged. `--log-
slave-updates` is enabled by default, unless you specify `--skip-log-bin` to disable binary logging,
in which case MySQL also disables slave update logging by default. If you need to disable slave update
logging when binary logging is enabled, specify `--skip-log-slave-updates`.

`--log-slave-updates` enables replication servers to be chained. For example, you might want to set
up replication servers using this arrangement:

```
A -> B -> C
```
Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master and a slave. With binary logging and the \(--\text{log-slave-updates}\) option enabled, which are the default settings, updates received from A are logged by B to its binary log, and can therefore be passed on to C.

- \(--\text{master-info-file}=\text{file\_name}\)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>(--\text{master-info-file}=\text{file_name})</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>master.info</td>
</tr>
</tbody>
</table>

The name for the master info log, if \(--\text{master-info-repository}=\text{FILE}\) is set. The default name is master.info in the data directory. \(--\text{master-info-repository}=\text{FILE}\) is now deprecated. For information about the master info log, see Section 17.2.4.2, “Slave Status Logs”.

- \(--\text{master-retry-count}=\text{count}\)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>(--\text{master-retry-count}=#)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>86400</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The number of times that the slave tries to reconnect to the master before giving up. The default value is 86400 times. A value of 0 means “infinite”, and the slave attempts to connect forever. Reconnection attempts are triggered when the slave reaches its connection timeout (specified by the \(--\text{slave-net-timeout}\) option) without receiving data or a heartbeat signal from the master. Reconnection is attempted at intervals set by the \text{MASTER\_CONNECT\_RETRY} option of the \text{CHANGE MASTER TO} statement (which defaults to every 60 seconds).

This option is deprecated and will be removed in a future MySQL release. Use the \text{MASTER\_RETRY\_COUNT} option of the \text{CHANGE MASTER TO} statement instead.

- \(--\text{max-relay-log-size}=\text{size}\)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>(--\text{max-relay-log-size}=#)</td>
</tr>
<tr>
<td>System Variable</td>
<td>\text{max_relay_log_size}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\text{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 17.2.4.1, “The Slave Relay Log”.

- `--relay-log=file_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The base name for the relay log. The server creates relay log files in sequence by adding a numeric suffix to the base name.

For the default replication channel, the default base name for relay logs is `host_name-relay-bin`, using the name of the host machine. For non-default replication channels, the default base name for relay logs is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in this relay log.

The default location for relay log files is the data directory. You can use the `--relay-log` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory.

The relay log and relay log index on a replication server cannot be given the same names as the binary log and binary log index, whose names are specified by the `--log-bin` and `--log-bin-index` options. The server issues an error message and does not start if the binary log and relay log file base names would be the same.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; the default base name is used only if the option is not actually specified. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.4, “Specifying Program Options”.

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previously, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)
You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.

- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.

- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `--relay-log-index=file_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-index=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_index</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name for the index file for the relay log. If you do not specify the `--relay-log-index` option, but the `--relay-log` option is specified, its value is used as the default base name for the relay log index file. If the `--relay-log` option is also not specified, then for the default replication channel, the default name is `host_name-relay-bin.index`, using the name of the host machine. For non-default replication channels, the default name is `host_name-relay-bin-channel.index`, where `channel` is the name of the replication channel recorded in this relay log index.

The default location for relay log files is the data directory, or any other location that was specified using the `--relay-log` option. You can use the `--relay-log-index` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory.

The relay log and relay log index on a replication server cannot be given the same names as the binary log and binary log index, whose names are specified by the `--log-bin` and `--log-bin-index` options. The server issues an error message and does not start if the binary log and relay log file base names would be the same.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; the default base name is used only if the option is not actually specified. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.4, “Specifying Program Options”.

- `--relay-log-info-file=file_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-info-file=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>relay-log.info</code></td>
</tr>
</tbody>
</table>
The name for the relay log info file, if --relay-log-info-repository is set to FILE. The default name is relay-log.info in the data directory. --relay-log-info-repository=FILE is now deprecated. For information about the relay log info log, see Section 17.2.4.2, “Slave Status Logs”.

- **--relay-log-purge={0|1}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-purge</td>
</tr>
<tr>
<td>System Variable</td>
<td>relay_log_purge</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with SET GLOBAL relay_log_purge = N. Disabling purging of relay logs when using the --relay-log-recovery option risks data consistency and is therefore not crash-safe.

- **--relay-log-recovery={0|1}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-recovery</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

To provide a crash-safe slave, this option must be enabled (set to 1), --relay-log-info-repository must be set to TABLE, and relay-log-purge must be enabled. Enabling the --relay-log-recovery option when relay-log-purge is disabled risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe. See Making replication resilient to unexpected halts, for more information.

When using a multithreaded slave (in other words slave_parallel_workers is greater than 0), inconsistencies such as gaps can occur in the sequence of transactions that have been executed from the relay log. Enabling the --relay-log-recovery option when there are inconsistencies causes an error and the option has no effect. The solution in this situation is to issue START SLAVE UNTIL SQL_AFTER_MTS_GAPS, which brings the server to a more consistent state, then issue RESET SLAVE to remove the relay logs. See Section 17.4.1.33, “Replication and Transaction Inconsistencies” for more information.

- **--relay-log-space-limit=size**
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-space-limit=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_space_limit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit”. This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-do-db=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-do-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See Section 17.2.5.4, “Replication Channel Based Filters” for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.
The precise effect of this replication filter depends on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

**Warning**

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list is treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.feburary SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement’s effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```
If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```sql
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-ignore-db=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.
To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

As with \texttt{--replicate-do-db}, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

\textbf{Statement-based replication.} Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by \texttt{USE}) is \texttt{db_name}.

\textbf{Row-based replication.} Tells the slave SQL thread not to update any tables in the database \texttt{db_name}. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with \texttt{--replicate-ignore-db=sales} and you issue the following statements on the master:

\begin{verbatim}
USE prices;
UPDATE sales.january SET amount=amount+1000;
\end{verbatim}

The \texttt{UPDATE} statement \textit{is} replicated in such a case because \texttt{--replicate-ignore-db} applies only to the default database (determined by the \texttt{USE} statement). Because the \texttt{sales} database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the \texttt{UPDATE} statement's effects are \textit{not} propagated to the slave, and the slave's copy of the \texttt{sales.january} table is unchanged; in this instance, \texttt{--replicate-ignore-db=sales} causes \textit{all} changes made to tables in the master's copy of the \texttt{sales} database to be ignored by the slave.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 17.2.5, "How Servers Evaluate Replication Filtering Rules".

If you need cross-database updates to work, use \texttt{--replicate-wild-ignore-table=db_name.\%} instead. See Section 17.2.5, "How Servers Evaluate Replication Filtering Rules".

\textbf{Note}

This option affects replication in the same manner that \texttt{--binlog-ignore-db} affects binary logging, and the effects of the replication format on how \texttt{--replicate-ignore-db} affects replication behavior are the same as those of the logging format on the behavior of \texttt{--binlog-ignore-db}.

This option has no effect on \texttt{BEGIN}, \texttt{COMMIT}, or \texttt{ROLLBACK} statements.

\begin{itemize}
  \item \texttt{--replicate-do-table=db_name.tbl_name}
\end{itemize}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--replicate-do-table=name}</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to \texttt{--replicate-do-db}. See Section 17.2.5, "How Servers Evaluate Replication Filtering Rules". You can also create such a filter by issuing a \texttt{CHANGE REPLICATION FILTER REPlicate\_Do\_Table} statement.
This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See Section 17.2.5.4, “Replication Channel Based Filters” for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-ignore-table=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-ignore-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See Section 17.2.5.4, “Replication Channel Based Filters” for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.
This option affects only statements that apply to tables. It does not affect statements that apply only to
other database objects, such as stored routines. To filter statements operating on stored routines, use
one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-rewrite-db=old_name-&gt;new_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Tells the slave to create a replication filter that translates the default database (that is, the one selected
by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected
(not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option
multiple times. The server uses the first one with a `from_name` value that matches. The database name
translation is done before the `--replicate-*` rules are tested. You can also create such a filter by
issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

If you use this option on the command line and the `>` character is special to your command interpreter,
quote the option value. For example:

```
shell> mysql --replicate-rewrite-db="olddb->newdb"
```

This option supports channel specific replication filters, enabling multi-source replication slaves to use
specific filters for different sources. Specify the channel name followed by a colon, followed by the filter
specification. The first colon is interpreted as a separator, and any subsequent colons are interpreted
as literal colons. For example, to configure a channel specific replication filter on a channel named
`channel_1`, use:

```
shell> mysql --replicate-rewrite-db=channel_1:db_name1->db_name2
```

If you use a colon but do not specify a channel name, the option configures the replication filter for
the default replication channel. See Section 17.2.5.4, “Replication Channel Based Filters” for more
information.

#### Note

Global replication filters cannot be used on a MySQL server instance that is
configured for Group Replication, because filtering transactions on some servers
would make the group unable to reach agreement on a consistent state. Channel
specific replication filters can be used on replication channels that are not directly
involved with Group Replication, such as where a group member also acts as
a replication slave to a master that is outside the group. They cannot be used
on the `group_replication_applier` or `group_replication_recovery`
channels.

Statements in which table names are qualified with database names when using this option do not
work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have
a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have
started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute
`DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:
1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.

2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.

3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

- `--replicate-same-server-id`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-same-server-id</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. The option cannot be set to 1 when `--log-slave-updates` is enabled, which is the default.

By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=\text{db}\_name.\text{tbl}\_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-wild-do-table=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-wild-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See Section 17.2.5.4, “Replication Channel Based Filters” for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as
Replication and Binary Logging Options and Variables

a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

As an example, `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\_own\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-wild-ignore-table=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-wild-ignore:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See Section 17.2.5.4, “Replication Channel Based Filters” for more information.

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.
As an example, `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`. For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`  

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-host=host_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>report_host</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SETVAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master.

Note

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`  

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-password=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>report_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SETVAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`  

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-port=#</code></td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>report_port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>[slave_port]</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the slave (Bug #13333431). This is also the default value displayed by `SHOW SLAVE HOSTS`.

• `--report-user=user_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-user=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>report_user</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

• `--slave-checkpoint-group=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-checkpoint-group=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>

<tr>
<td>Default Value</td>
<td>512</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524280</td>
</tr>
<tr>
<td>Block Size</td>
<td>8</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

Sets the maximum number of transactions that can be processed by a multithreaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multithreading is not enabled.

**Note**
Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this option. See Section 22.6.3, “Known Issues in NDB Cluster Replication”, for more information.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (Exception: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- **--slave-checkpoint-period=**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-checkpoint-period=##</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4G</td>
</tr>
</tbody>
</table>

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multithreading is not enabled.

**Note**
Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this option. See Section 22.6.3, “Known Issues in NDB Cluster Replication”, for more information.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- **--slave-parallel-workers**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-parallel-workers=##</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
Enables multithreading on the slave and sets the number of slave applier threads for executing replication transactions in parallel. When the value is a number greater than 0, the slave is a multithreaded slave with the specified number of applier threads, plus a coordinator thread to manage them. If you are using multiple replication channels, each channel has this number of threads.

Retrying of transactions is supported when multithreading is enabled on a slave. When `slave_preserve_commit_order=1`, transactions on a slave are externalized on the slave in the same order as they appear in the slave's relay log. The way in which transactions are distributed among applier threads is configured by `--slave-parallel-type`.

To disable parallel execution, set this option to 0, which gives the slave a single applier thread and no coordinator thread. With this setting, the `--slave-parallel-type` and `slave_preserve_commit_order` options have no effect and are ignored.

---

**Note**

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this option. See Section 22.6.3, "Known Issues in NDB Cluster Replication", for more information.

* `--slave-pending-jobs-size-max= ##`

---

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.12)</td>
<td>128M</td>
</tr>
<tr>
<td>Default Value (&lt; 8.0.11)</td>
<td>16M</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16GiB</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

For multithreaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multithreading is not enabled.

The minimum possible value for this option is 1024 bytes; the default is 128MB. The maximum possible value is 18446744073709551615 (16 exbibytes). Values that are not exact multiples of 1024 bytes are rounded down to the next lower multiple of 1024 bytes prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

* `--skip-slave-start`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--skip-slave-start</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave-load-tmpdir=dir_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--slave-load-tmpdir=dir_name</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>slave_load_tmpdir</code></td>
</tr>
<tr>

<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Directory name</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>/tmp</code></td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--slave-max-allowed-packet=#</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><code>1073741824</code></td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td><code>1024</code></td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td><code>1073741824</code></td>
</tr>
</tbody>
</table>

This option sets the maximum packet size in bytes that the slave SQL and I/O threads can handle. It is possible for a replication master to write binary log events longer than its `max_allowed_packet` setting once the event header is added. The setting for `slave_max_allowed_packet` must be larger than the `max_allowed_packet` setting on the master, so that large updates using row-based replication do not cause replication to fail.
The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-net-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_net_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data or a heartbeat signal from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds (one minute). The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `MASTER_RETRY_COUNT` option for the `CHANGE MASTER TO` statement.

The heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good, is controlled by the `MASTER_HEARTBEAT_PERIOD` option for the `CHANGE MASTER TO` statement. The heartbeat interval defaults to half the value of `--slave-net-timeout`, and it is recorded in the master info log and shown in the `replication_connection_configuration` Performance Schema table. Note that a change to the value or default setting of `--slave-net-timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. If the connection timeout is changed, you must also issue `CHANGE MASTER TO` to adjust the heartbeat interval to an appropriate value so that it occurs before the connection timeout.

- `--slave-parallel-type=type`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-parallel-type=type</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>DATABASE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>DATABASE</code></td>
</tr>
<tr>
<td></td>
<td><code>LOGICAL_CLOCK</code></td>
</tr>
</tbody>
</table>
When using a multithreaded slave (`slave_parallel_workers` is greater than 0), this option specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The option has no effect on slaves for which multithreading is not enabled. The possible values are:

- **LOGICAL_CLOCK**: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. The dependencies between transactions are tracked based on their timestamps to provide additional parallelization where possible. When this value is set, the `binlog_transaction_dependency_tracking` system variable can be used on the master to specify that write sets are used for parallelization in place of timestamps, if a write set is available for the transaction and gives improved results compared to timestamps.

- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. There must be no cross-database constraints, as such constraints may be violated on the slave.

When `slave_preserve_commit_order=1` is set, you can only use **LOGICAL_CLOCK**.

If your replication topology uses multiple levels of slaves, **LOGICAL_CLOCK** may achieve less parallelization for each level the slave is away from the master. You can reduce this effect by using `binlog_transaction_dependency_tracking` on the master to specify that write sets are used instead of timestamps for parallelization where possible.

- **slave-rows-search-algorithms=list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-rows-search-algorithms=list</code></td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td><code>INDEX_SCAN, HASH_SCAN</code></td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.1)</td>
<td><code>TABLE_SCAN, INDEX_SCAN</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>TABLE_SCAN, INDEX_SCAN</code></td>
</tr>
<tr>
<td></td>
<td><code>INDEX_SCAN, HASH_SCAN</code></td>
</tr>
<tr>
<td></td>
<td><code>TABLE_SCAN, HASH_SCAN</code></td>
</tr>
<tr>
<td></td>
<td><code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code>)</td>
</tr>
</tbody>
</table>

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches, in particular whether hash scans are used. The option sets the initial value for the `slave_rows_search_algorithms` system variable.

Specify a comma-separated list of the following combinations of 2 values from the list `INDEX_SCAN, TABLE_SCAN, HASH_SCAN`. For the option, the list need not be quoted, but must contain no spaces, whether or not quotes are used. The recommended combinations (lists) and their effects are shown in the following table:

<table>
<thead>
<tr>
<th>Index used / option value</th>
<th><code>INDEX_SCAN, HASH_SCAN</code></th>
<th><code>INDEX_SCAN, TABLE_SCAN</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary key or unique key</td>
<td>Index scan</td>
<td>Index scan</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Index used / option value</th>
<th>INDEX_SCAN, HASH_SCAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Other) Key</td>
<td>Hash scan over index</td>
</tr>
<tr>
<td>No index</td>
<td>Hash scan</td>
</tr>
</tbody>
</table>

- The default value is **INDEX_SCAN, HASH_SCAN**. With this setting, hashing is used for any searches that do not use a primary or unique key. Specifying **INDEX_SCAN, HASH_SCAN** has the same effect as specifying **INDEX_SCAN, TABLE_SCAN, HASH_SCAN**, which is allowed.

- To remove hashing, set **INDEX_SCAN, TABLE_SCAN**. With this setting, all searches that can use indexes do use them, and searches without any indexes use table scans.

- Do not use the combination **TABLE_SCAN, HASH_SCAN**. This setting forces hashing for all searches. It has no advantage over **INDEX_SCAN, HASH_SCAN**, and it can lead to “record not found” errors or duplicate key errors in the case of a single event containing multiple updates to the same row, or updates that are order-dependent.

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement.

It is possible to specify a single value, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting **INDEX_SCAN** alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

- `--slave-skip-errors=[err_code1, err_code2, ...|all|ddl_exist_errors]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-skip-errors=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_skip_errors</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>[list of error codes]</td>
</tr>
<tr>
<td></td>
<td>all</td>
</tr>
<tr>
<td></td>
<td>ddl_exist_errors</td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.
For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

The shorthand value `ddl_exist_errors` is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave’s data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-sql-verify-checksum=value</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error.

The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- `--abort-slave-event-count

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--abort-slave-event-count=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays *Yes* in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

- `--disconnect-slave-event-count

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--disconnect-slave-event-count</code></td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
</tbody>
</table>
### Options for Logging Slave Status to Tables

Replication slave status information is logged to an InnoDB table in the `mysql` database. Before MySQL 8.0, this information could alternatively be logged to a file in the data directory, but the use of that format is now deprecated. Writing of the master info log and the relay log info log can be configured separately using the two server options listed here:

- `--master-info-repository={TABLE|FILE}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--master-info-repository=FILE</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td><code>TABLE</code></td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.1)</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>FILE</code> <code>TABLE</code></td>
</tr>
</tbody>
</table>

This option determines whether the slave server logs master status and connection information to an InnoDB table in the `mysql` database, or to a file in the data directory.

The default setting is `TABLE`. As an InnoDB table, the master info log is named `mysql.slave_master_info`. The `TABLE` setting is required when multiple replication channels are configured.

The `FILE` setting is deprecated, and will be removed in a future release. As a file, the master info log is named `master.info` by default, and you can change this name using the `--master-info-file` option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the `sync_master_info` system variable. You can only change the setting when no replication threads are executing.

- `--relay-log-info-repository={TABLE|FILE}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--relay-log-info-repository=FILE</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td><code>TABLE</code></td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.1)</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>FILE</code> <code>TABLE</code></td>
</tr>
</tbody>
</table>
This option determines whether the slave server logs its position in the relay logs to an InnoDB table in the `mysql` database, or to a file in the data directory.

The default setting is `TABLE`. As an InnoDB table, the relay log info log is named `mysql.slave_relay_log_info`. The `TABLE` setting is required when multiple replication channels are configured. The `TABLE` setting for the relay log info log is also required to make replication resilient to unexpected halts, for which the `--relay-log-recovery` option must also be enabled. See [Making replication resilient to unexpected halts](https://dev.mysql.com/doc/refman/8.0/en/innodb-replication-slave.html) for more information.

The `FILE` setting is deprecated, and will be removed in a future release. As a file, the relay log info log is named `relay-log.info` by default, and you can change this name using the `--relay-log-info-file` option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable. You can only change the setting when no replication threads are executing.

The slave status log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

### System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- **init_slave**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--init-slave=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>init_slave</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

**Note**

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 13.4.2.6, “START SLAVE Syntax”](https://dev.mysql.com/doc/refman/8.0/en/replication-slave-start.html), for more information.

- **log_slow_slave_statements**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>log_slow_slave_statements</code></td>
</tr>
</tbody>
</table>
When the slow query log is enabled, this variable enables logging for queries that have taken more than \texttt{long_query_time} seconds to execute on the slave. Setting this variable has no immediate effect. The state of the variable applies on all subsequent \texttt{START SLAVE} statements.

Note that all statements logged in row format in the master will not be logged in the slave's slow log, even if \texttt{log_slow_slave_statements} is enabled.

- **\texttt{master_info_repository}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
<td><strong>Value</strong></td>
</tr>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--master-info-repository=FILE</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{master_info_repository}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td>\texttt{TABLE}</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.1)</td>
<td>\texttt{FILE}</td>
</tr>
<tr>
<td>Valid Values</td>
<td>\texttt{FILE}</td>
</tr>
<tr>
<td></td>
<td>\texttt{TABLE}</td>
</tr>
</tbody>
</table>

The setting of this variable determines whether the slave server logs master status and connection information to an InnoDB table in the \texttt{mysql} database, or to a file in the data directory.

The default setting is \texttt{TABLE}. As an InnoDB table, the master info log is named \texttt{mysql.slave_master_info}. The \texttt{TABLE} setting is required when multiple replication channels are configured.

The \texttt{FILE} setting is deprecated, and will be removed in a future release. As a file, the master info log is named \texttt{master.info} by default, and you can change this name using the \texttt{--master-info-file} option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the \texttt{sync_master_info} system variable. You can only change the setting when no replication threads are executing.

- **\texttt{max_relay_log_size}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
<td><strong>Value</strong></td>
</tr>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--max-relay-log-size=#}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{max_relay_log_size}</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 17.2.2, “Replication Implementation Details”.

- `relay_log`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The base name for relay log files, with no paths and no file extension. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in this relay log.

- `relay_log_basename`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>relay_log_basename</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>datadir + '/' + hostname + '-relay-bin'</code></td>
</tr>
</tbody>
</table>

Holds the name and complete path to the relay log file.

- `relay_log_index`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-index</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_index</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>*host_name*-relay-bin.index</code></td>
</tr>
</tbody>
</table>

The name of the relay log index file for the default replication channel. The default name is `host_name-relay-bin.index`.

- **relay_log_info_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-info-file=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_info_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>relay-log.info</code></td>
</tr>
</tbody>
</table>

The name of the relay log info log, when `relay_log_info_repository=FILE` is set. The default name is `relay-log.info` in the data directory. `relay_log_info_repository=FILE` is now deprecated.

- **relay_log_info_repository**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>relay_log_info_repository</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value <code>&gt;= 8.0.2</code></td>
<td>TABLE</td>
</tr>
<tr>
<td>Default Value <code>&lt;= 8.0.1</code></td>
<td>FILE</td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td></td>
<td><code>TABLE</code></td>
</tr>
</tbody>
</table>

The setting of this variable determines whether the slave server logs its position in the relay logs to an InnoDB table in the `mysql` database, or to a file in the data directory.
The default setting is TABLE. As an InnoDB table, the relay log info log is named mysql_slave_relay_log_info. The TABLE setting is required when multiple replication channels are configured. The TABLE setting for the relay log info log is also required to make replication resilient to unexpected halts, for which the --relay-log-recovery option must also be enabled. See Making replication resilient to unexpected halts for more information.

The FILE setting is deprecated, and will be removed in a future release. As a file, the relay log info log is named relay-log.info by default, and you can change this name using the --relay-log-info-file option.

The setting for the location of this slave status log has a direct influence on the effect had by the setting of the sync_relay_log_info system variable. You can only change the setting when no replication threads are executing.

- relay_log_purge

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-purge</td>
</tr>
<tr>
<td>System Variable</td>
<td>relay_log_purge</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (ON).

- relay_log_recovery

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-recovery</td>
</tr>
<tr>
<td>System Variable</td>
<td>relay_log_recovery</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This global variable is read-only; its value can be changed by starting the slave with the --relay-log-recovery option, which should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed, and must be used in order to guarantee a crash-safe slave. The default value is 0 (disabled).

This variable also interacts with relay-log-purge, which controls purging of logs when they are no longer needed. Enabling the --relay-log-recovery option when relay-log-purge is disabled
risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multithreaded mode, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `relay_log_space_limit`  
  
<table>

<td>8192</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8192</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
The `rpl_read_size` system variable controls the minimum amount of data in bytes that is read from the binary log files and relay log files. If heavy disk I/O activity for these files is impeding performance for the database, increasing the read size might reduce file reads and I/O stalls when the file data is not currently cached by the operating system.

The minimum and default value for `rpl_read_size` is 8192 bytes. The value must be a multiple of 4KB. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on masters and coordinator threads on slaves. Setting a large value might therefore have an impact on memory consumption for servers.

---

**rpl_semi_sync_slave_enabled**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_slave_enabled</code></td>

<tr>
<td>Default Value</td>
<td>32</td>
</tr>
</tbody>
</table>

The semisynchronous replication debug trace level on the slave. See `rpl_semi_sync_master_trace_level` for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

---

**rpl_stop_slave_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rpl-stop-slave-timeout=seconds</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>rpl_stop_slave_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
You can control the length of time (in seconds) that `STOP SLAVE` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave.

The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements.

This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client returns an error message stating that the command execution is incomplete. The client then stops waiting for the slave threads to stop, but the slave threads continue to try to stop, and the `STOP SLAVE` instruction remains in effect. Once the slave threads are no longer busy, the `STOP SLAVE` statement is executed and the slave stops.

- `slave_checkpoint_group`

Sets the maximum number of transactions that can be processed by a multithreaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

Note

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 22.6.3, “Known Issues in NDB Cluster Replication”, for more information.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.
The minimum allowed value for this variable is 32, unless the server was built using \texttt{-DWITH_DEBUG}, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (\textit{Exception}: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- \textit{slave_checkpoint_period}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--slave-checkpoint-period=}#</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{slave_checkpoint_period}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4G</td>
</tr>
</tbody>
</table>

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded slave as shown by \texttt{SHOW SLAVE STATUS}. Setting this variable has no effect on slaves for which multithreading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

\textbf{Note}

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section \ref{known-issues-in-ndb-cluster-replication}, \texttt{``Known Issues in NDB Cluster Replication''}, for more information.

This variable works in combination with the \texttt{slave_checkpoint_group} system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using \texttt{-DWITH_DEBUG}, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- \textit{slave_compressed_protocol}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--slave-compressed-protocol}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{slave_compressed_protocol}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>\texttt{OFF}</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

Whether to use compression of the slave/master protocol if both the slave and the master support it. The default is that compression is not used. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running I/O thread (for example after issuing a `CHANGE MASTER TO MASTER_RETRY_COUNT` statement).

- **slave_exec_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-exec-mode=mode</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_exec_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>IDEMPOTENT</code> (NDB)</td>
</tr>
<tr>
<td></td>
<td><code>STRICT</code> (Other)</td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>IDEMPOTENT</code></td>
</tr>
<tr>
<td></td>
<td><code>STRICT</code></td>
</tr>
</tbody>
</table>

Controls how a slave thread resolves conflicts and errors during replication. **IDEMPOTENT** mode causes suppression of duplicate-key and no-key-found errors; **STRICT** means no such suppression takes place.

**IDEMPOTENT** mode is intended for use in multi-master replication, circular replication, and some other special replication scenarios for NDB Cluster Replication. (See Section 22.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”, and Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.) NDB Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as **IDEMPOTENT**.

In MySQL Server 8.0, **STRICT** mode is the default value.

Setting this variable takes immediate effect for all replication channels, including running channels.

For storage engines other than NDB, **IDEMPOTENT** mode should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored. It is meant to be used in fail-over scenarios for NDB Cluster where multi-master replication or circular replication is employed, and is not recommended for use in other cases.

- **slave_load_tmpdir**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-load-tmpdir=dir_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_load_tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

3114
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>/tmp</td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files for replicating `LOAD DATA` statements. Setting this variable takes effect for all replication channels immediately, including running channels.

- `slave_max_allowed_packet`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_max_allowed_packet</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

This option sets the maximum packet size in bytes that the slave SQL and I/O threads can handle. Setting this variable takes effect for all replication channels immediately, including running channels. It is possible for a replication master to write binary log events longer than its `max_allowed_packet` setting once the event header is added. The setting for `slave_max_allowed_packet` must be larger than the `max_allowed_packet` setting on the master, so that large updates using row-based replication do not cause replication to fail.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-net-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_net_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
The number of seconds to wait for more data or a heartbeat signal from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The default value is 60 seconds (one minute). The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `MASTER_RETRY_COUNT` option for the `CHANGE MASTER TO` statement.

The heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good, is controlled by the `MASTER_HEARTBEAT_PERIOD` option for the `CHANGE MASTER TO` statement. The heartbeat interval defaults to half the value of `slave_net_timeout`, and it is recorded in the master info log and shown in the `replication_connection_configuration` Performance Schema table. Note that a change to the value or default setting of `slave_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. If the connection timeout is changed, you must also issue `CHANGE MASTER TO` to adjust the heartbeat interval to an appropriate value so that it occurs before the connection timeout.

- `slave_parallel_type=type`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-parallel-type=type</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>DATABASE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>DATABASE, LOGICAL_CLOCK</td>
</tr>
</tbody>
</table>

When using a multithreaded slave (`slave_parallel_workers` is greater than 0), this variable specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The variable has no effect on slaves for which multithreading is not enabled. The possible values are:

- **LOGICAL_CLOCK**: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. The dependencies between transactions are tracked based on their timestamps to provide additional parallelization where possible. When this value is set, the `binlog_transaction_dependency_tracking` system variable can be used on the master to specify that write sets are used for parallelization in place of timestamps, if a write set is available for the transaction and gives improved results compared to timestamps.

- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. There must be no cross-database constraints, as such constraints may be violated on the slave.

When `slave_preserve_commit_order=1` is set, you can only use **LOGICAL_CLOCK**.

If your replication topology uses multiple levels of slaves, **LOGICAL_CLOCK** may achieve less parallelization for each level the slave is away from the master. You can reduce this effect by using `binlog_transaction_dependency_tracking` on the master to specify that write sets are used instead of timestamps for parallelization where possible.

- `slave_parallel_workers`
### slave_parallel_workers

Enables multithreading on the slave and sets the number of slave applier threads for executing replication transactions in parallel. When the value is a number greater than 0, the slave is a multithreaded slave with the specified number of applier threads, plus a coordinator thread to manage them. If you are using multiple replication channels, each channel has this number of threads.

**Note**
Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 22.6.3, “Known Issues in NDB Cluster Replication”, for more information.

Retrying of transactions is supported when multithreading is enabled on a slave. When `slave_preserve_commit_order=1`, transactions on a slave are externalized on the slave in the same order as they appear in the slave’s relay log. The way in which transactions are distributed among applier threads is configured by `--slave-parallel-type`.

To disable parallel execution, set this option to 0, which gives the slave a single applier thread and no coordinator thread. With this setting, the `--slave-parallel-type` and `slave_preserve_commit_order` options have no effect and are ignored.

Setting `slave_parallel_workers` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

- `slave_pending_jobs_size_max`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--slave-parallel-workers=#</td>
</tr>

<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Note: Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 22.6.3, “Known Issues in NDB Cluster Replication”, for more information.
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>16E1B</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

For multithreaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The minimum possible value for this variable is 1024 bytes; the default is 128MB. The maximum possible value is 18446744073709551615 (16 exbibytes). Values that are not exact multiples of 1024 bytes are rounded down to the next lower multiple of 1024 bytes prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

- `slave_preserve_commit_order`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-preserve-commit-order=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_preserve_commit_order</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

For multithreaded slaves, the setting 1 for this variable ensures that transactions are externalized on the slave in the same order as they appear in the slave’s relay log, and prevents gaps in the sequence of transactions that have been executed from the relay log. This variable has no effect on slaves for which multithreading is not enabled.

`slave_preserve_commit_order=1` requires that `--log-bin` and `--log-slave-updates` are enabled on the slave, and `--slave-parallel-type` is set to LOGICAL_CLOCK.

With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the slave thread is waiting for other workers to commit their transactions it reports its status as *Waiting for preceding transaction to commit*. With this mode, a multithreaded slave never enters a state that the master was not in. This supports the use of replication for read scale-out. See Section 17.3.5, “Using Replication for Scale-Out”.

Before changing this variable, all replication threads (for all replication channels if you are using multiple replication channels) must be stopped. If `slave_preserve_commit_order=0` is set, the transactions that the slave applies in parallel may commit out of order. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the master have been executed on the slave. There is a chance of gaps in the sequence of transactions that have been executed from the slave’s relay log. This has implications for logging and recovery when using
Replication and Binary Logging Options and Variables

a multithreaded slave. Note that the setting `slave_preserve_commit_order=1` prevents gaps, but does not prevent gap-free low-watermark positions (where `Exec_master_log_pos` is behind the position up to which transactions have been executed). See Section 17.4.1.33, “Replication and Transaction Inconsistencies” for more information.

- `slave_rows_search_algorithms`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slave_rows_search_algorithms</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td><strong>Default Value (&gt;= 8.0.2)</strong></td>
<td><code>INDEX_SCAN,HASH_SCAN</code></td>
</tr>
<tr>
<td><strong>Default Value (&lt;= 8.0.1)</strong></td>
<td><code>TABLE_SCAN,INDEX_SCAN</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>TABLE_SCAN,INDEX_SCAN</code>, <code>INDEX_SCAN,HASH_SCAN</code>, <code>TABLE_SCAN,HASH_SCAN</code> (equivalent to <code>INDEX_SCAN,HASH_SCAN</code>)</td>
</tr>
</tbody>
</table>

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches, in particular whether hash scans are used. Setting this variable takes effect for all replication channels immediately, including running channels. The initial setting for the system variable can be specified using the `--slave-rows-search-algorithms` option.

Specify a comma-separated list of the following combinations of 2 values from the list `INDEX_SCAN, TABLE_SCAN, HASH_SCAN`. For the system variable, the value is expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. The recommended combinations (lists) and their effects are shown in the following table:

<table>
<thead>
<tr>
<th>Index used / option value</th>
<th><code>INDEX_SCAN,HASH_SCAN</code></th>
<th><code>INDEX_SCAN,TABLE_SCAN</code>, <code>INDEX_SCAN,HASH_SCAN</code></th>
<th><code>TABLE_SCAN,INDEX_SCAN</code>, <code>TABLE_SCAN,HASH_SCAN</code>, <code>INDEX_SCAN,HASH_SCAN</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary key or unique key</td>
<td>Index scan</td>
<td>Index scan</td>
<td></td>
</tr>
<tr>
<td>(Other) Key</td>
<td>Hash scan over index</td>
<td>Index scan</td>
<td></td>
</tr>
<tr>
<td>No index</td>
<td>Hash scan</td>
<td>Table scan</td>
<td></td>
</tr>
</tbody>
</table>

- The default value is `INDEX_SCAN,HASH_SCAN`. With this setting, hashing is used for any searches that do not use a primary or unique key. Specifying `INDEX_SCAN,HASH_SCAN` has the same effect as specifying `INDEX_SCAN,TABLE_SCAN,HASH_SCAN`, which is allowed.

- To remove hashing, set `INDEX_SCAN,TABLE_SCAN`. With this setting, all searches that can use indexes do use them, and searches without any indexes use table scans.

- Do not use the combination `TABLE_SCAN,HASH_SCAN`. This setting forces hashing for all searches. It has no advantage over `INDEX_SCAN,HASH_SCAN`, and it can lead to “record not found” errors or
duplicate key errors in the case of a single event containing multiple updates to the same row, or
updates that are order-dependent.

The order in which the algorithms are specified in the list does not make any difference in the order in
which they are displayed by a `SELECT` or `SHOW VARIABLES` statement.

It is possible to specify a single value, but this is not optimal, because setting a single value limits
searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as
in that case searches are unable to find rows at all if no index is present.

- **slave_skip_errors**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-skip-errors=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_skip_errors</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td><code>[list of error codes]</code></td>
</tr>
<tr>
<td></td>
<td><code>all</code></td>
</tr>
<tr>
<td></td>
<td><code>ddl_exist_errors</code></td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve
the inconsistency in the data manually. This variable causes the slave SQL thread to continue replication
when a statement returns any of the errors listed in the variable value.

- **slave_sql_verify_checksum**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_sql_verify_checksum</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of
a mismatch, the slave stops with an error. Setting this variable takes effect for all replication channels
immediately, including running channels.
Note

The slave I/O thread always reads checksums if possible when accepting events from over the network.

- `slave_transaction_retries`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-transaction-retries=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_transaction_retries</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>

<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the maximum number of times for replication slave SQL threads on a single-threaded or multithreaded slave to automatically retry failed transactions before stopping. Setting this variable takes effect for all replication channels immediately, including running channels. The default value is 10. Setting the variable to 0 disables automatic retrying of transactions.

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's `innodb_lock_wait_timeout` or NDB's `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. Transactions with a non-temporary error are not retried.

The Performance Schema table `replication_applier_status` shows the number of retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column. The Performance Schema table `replication_applier_status_by_worker` shows detailed information on transaction retries by individual applier threads on a single-threaded or multithreaded replication slave, and identifies the errors that caused the last transaction and the transaction currently in progress to be reattempted.

- `slave_type_conversions`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-type-conversions=set</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_type_conversions</code></td>
</tr>
<tr>

</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>
### Replication and Binary Logging Options and Variables

Controls the type conversion mode in effect on the slave when using row-based replication. Its value is a comma-delimited set of zero or more elements from the list: `ALL_LOSSY`, `ALL_NON_LOSSY`, `ALL_SIGNED`, `ALL_UNSIGNED`. Set this variable to an empty string to disallow type conversions between the master and the slave. Setting this variable takes effect for all replication channels immediately, including running channels.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

**sql_slave_skip_counter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_slave_skip_counter</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The number of events from the master that a slave server should skip. Setting the option has no immediate effect. The variable applies to the next `START SLAVE` statement; the next `START SLAVE` statement also changes the value back to 0. When this variable is set to a nonzero value and there are multiple replication channels configured, the `START SLAVE` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `--gtid-mode=ON`. If you need to skip transactions when employing GTIDs, use `gtid_executed` from the master instead. See [Injecting empty transactions](#), for information about how to do this.

**Important**

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”.

**sync_master_info**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sync-master-info=#</code></td>
</tr>
<tr>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

**master_info_repository = FILE.** If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

**master_info_repository = TABLE.** If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

• **sync_relay_log**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sync-relay-log=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>sync_relay_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).
### sync_relay_log_info

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sync-relay-log-info=#</td>
</tr>
<tr>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

The effects of this variable on the replication slave depend on the server's `relay_log_info_repository` setting (FILE or TABLE). If the setting is TABLE, the effects of the variable also depend on whether the storage engine used by the relay log info table is transactional (such as InnoDB) or not transactional (MyISAM). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are as follows:

- **sync_relay_log_info = 0**
  - If `relay_log_info_repository` is set to FILE, the MySQL server performs no synchronization of the `relay-log.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.
  - If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is transactional, the table is updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)
  - If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is not transactional, the table is never updated.

- **sync_relay_log_info = N > 0**
  - If `relay_log_info_repository` is set to FILE, the slave synchronizes its `relay-log.info` file to disk (using `fdatasync()`) after every N transactions.
  - If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is transactional, the table is updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)
  - If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is not transactional, the table is updated after every N events.
17.1.6.4 Binary Logging Options and Variables

- **Startup Options Used with Binary Logging**
- **System Variables Used with Binary Logging**

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.4, “The Binary Log”. For additional information about using MySQL server options and system variables, see Section 5.1.7, “Server Command Options”, and Section 5.1.8, “Server System Variables”.

**Startup Options Used with Binary Logging**

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- **--binlog-row-event-max-size=N**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-event-max-size=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

When row-based binary logging is used, this setting is a soft limit on the maximum size of a row-based binary log event, in bytes. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded. The value must be (or else gets rounded down to) a multiple of 256. The default is 8192 bytes.

- **--binlog-rows-query-log-events**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-rows-query-log-events</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option enables `binlog_rows_query_log_events`, which causes the MySQL Server to write informational log events such as row query log events into its binary log.

- **--log-bin[=base_name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-bin=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

Specifies the base name to use for binary log files. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. The binary log is a sequence of files with a base name and numeric extension. The `--log-bin` option value is the base
name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name.

If you do not supply the `--log-bin` option, MySQL uses `binlog` as the default base name for the binary log files. For compatibility with earlier releases, if you supply the `--log-bin` option with no string or with an empty string, the base name defaults to `host_name-bin`, using the name of the host machine.

The default location for binary log files is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

In earlier MySQL versions, binary logging was disabled by default, and was enabled if you specified the `--log-bin` option. From MySQL 8.0, binary logging is enabled by default, whether or not you specify the `--log-bin` option. The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default. It is possible to enable binary logging in this case by specifying the `--log-bin` option. When binary logging is enabled, the `log_bin` system variable, which shows the status of binary logging on the server, is set to ON.

To disable binary logging, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence. When binary logging is disabled, the `log_bin` system variable is set to OFF.

When GTIDs are in use on the server, if you disable binary logging when restarting the server after an abnormal shutdown, some GTIDs are likely to be lost, causing replication to fail. In a normal shutdown, the set of GTIDs from the current binary log file is saved in the `mysql.gtid_executed` table. Following an abnormal shutdown where this did not happen, during recovery the GTIDs are added to the table from the binary log file, provided that binary logging is still enabled. If binary logging is disabled for the server restart, the server cannot access the binary log file to recover the GTIDs, so replication cannot be started. Binary logging can be disabled safely after a normal shutdown.

The `--log-slave-updates` and `--slave-preserve-commit-order` options require binary logging. If you disable binary logging, either omit these options, or specify `--skip-log-slave-updates` and `--skip-slave-preserve-commit-order`. MySQL disables these options by default when `--skip-log-bin` or `--disable-log-bin` is specified. If you specify `--log-slave-updates` or `--slave-preserve-commit-order` together with `--skip-log-bin` or `--disable-log-bin`, a warning or error message is issued.

In MySQL 5.7, a server ID had to be specified when binary logging was enabled, or the server would not start. In MySQL 8.0, the `server_id` system variable is set to 1 by default. The server can now be started with this default server ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly using the `--server-id` option. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

For information on the format and management of the binary log, see Section 5.4.4, “The Binary Log”.

- `--log-bin-index[=file_name]`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-bin-index=file_name</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name for the index file for the binary log. The binary log index file contains the names of all used binary log files. By default, it has the same location and base name as you specified for the binary log files using the `--log-bin` option, plus the extension `.index`. If you did not supply the `--log-bin` option, the default name for the binary log index file is `binlog.index`. If you supplied the `--log-bin` option with no string or an empty string, the default name for the binary log index file is `host_name-bin.index`, using the name of the host machine.

For information on the format and management of the binary log, see Section 5.4.4, “The Binary Log”.

- `--log-bin-trust-function-creators=[{0|1}]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-bin-trust-function-creators</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_bin_trust_function_creators</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See Section 24.7, “Binary Logging of Stored Programs”.

- `--log-bin-use-v1-row-events=[{0|1}]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-bin-use-v1-row-events=[{0</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_bin_use_v1_row_events</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

MySQL 8.0 uses Version 2 binary log row events, which cannot be read by MySQL Server releases prior to MySQL 5.6.6. Setting this option to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in those releases, and thus produce binary logs that can be read by slaves at those releases. Setting `--log-bin-use-v1-row-events` to 0 (the default) causes `mysqld` to use Version 2 binary log events.
The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

```
--log-bin-use-v1-row-events
```

is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 17.1.6.3, “Replication Slave Options and Variables”.

- `--binlog-do-db=db_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-do-db=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

**Warning**

To specify multiple databases you **must** use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is **not** logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.
Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```sql
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```sql
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```sql
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```sql
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```sql
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--binlog-ignore-db=name</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

When there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes all changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** MySQL supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--binlog-checksum=type</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>String</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>CRC32</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE</td>
</tr>
<tr>
<td></td>
<td>CRC32</td>
</tr>
</tbody>
</table>

Enabling this option causes the master to write checksums for events written to the binary log. Set to NONE to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported, and CRC32 is the default. You cannot change the setting for this option within a transaction.

- **--master-verify-checksum={0|1}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--master-verify-checksum=name</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

To control reading of checksums by the slave (from the relay) log, use the **--slave-sql-verify-checksum** option.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- **--max-binlog-dump-events=N**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-binlog-dump-events=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

- **--sporadic-binlog-dump-fail**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sporadic-binlog-dump-fail</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

**System Variables Used with Binary Logging**

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- **binlog_cache_size**
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-cache-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size of the cache to hold changes to the binary log during a transaction. When binary logging is enabled on the server (with the `log_bin` system variable set to ON), a binary log cache is allocated for each client if the server supports any transactional storage engines. If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, “The Binary Log”.

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>binlog_checksum</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>CRC32</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE</td>
</tr>
<tr>
<td></td>
<td>CRC32</td>
</tr>
</tbody>
</table>

When enabled, this variable causes the master to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32`. You cannot change the value of `binlog_checksum` within a transaction.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.
Setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096)

If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- **binlog_direct_non_transactional_updates**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-direct-non-transactional-updates [=value]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_direct_non_transactional_updates</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
</tbody>
</table>

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

**Important**

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

This variable has no effect when the binary log format is `ROW` or `MIXED`.

- **binlog_encryption**
Enables encryption for binary log files and relay log files on this server. OFF is the default. ON sets encryption on for binary log files and relay log files. Binary logging does not need to be enabled on the server to enable encryption, so you can encrypt the relay log files on a slave that has no binary log. To use encryption, a keyring plugin must be installed and configured to supply MySQL Server's keyring service. For instructions to do this, see Section 6.5.4, “The MySQL Keyring”. Any supported keyring plugin can be used to store binary log encryption keys.

When you first start the server with binary log encryption enabled, a new binary log encryption key is generated before the binary log and relay logs are initialized. This key is used to encrypt a file password for each binary log file (if the server has binary logging enabled) and relay log file (if the server has replication channels), and further keys generated from the file passwords are used to encrypt the data in the files. Relay log files are encrypted for all channels, including Group Replication applier channels and new channels that are created after encryption is activated. The binary log index file and relay log index file are never encrypted.

If you activate encryption while the server is running, a new binary log encryption key is generated at that time. The exception is if encryption was active previously on the server and was then disabled, in which case the binary log encryption key that was in use before is used again. The binary log file and relay log files are rotated immediately, and file passwords for the new files and all subsequent binary log files and relay log files are encrypted using this binary log encryption key. Existing binary log files and relay log files still present on the server are not automatically encrypted, but you can purge them if they are no longer needed.

If you deactivate encryption by changing the `binlog_encryption` system variable to OFF, the binary log file and relay log files are rotated immediately and all subsequent logging is unencrypted. Previously encrypted files are not automatically decrypted, but the server is still able to read them. SUPER privileges or the `BINLOG_ENCRYPTION_ADMIN` privilege are required to activate or deactivate encryption while the server is running. Group Replication applier channels are not included in the relay log rotation request, so unencrypted logging for these channels does not start until their logs are rotated in normal use.

For more information on binary log file and relay log file encryption, see Section 17.3.10, “Encrypting Binary Log Files and Relay Log Files”.

### binlog_error_action

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-error-action[=value]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_error_action</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ABORT_SERVER</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IGNORE_ERROR, ABORT_SERVER</td>
</tr>
</tbody>
</table>

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's binary log to become inconsistent and replication slaves to lose synchronization.

This variable defaults to **ABORT_SERVER**, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”).

When `binlog_error_action` is set to **IGNORE_ERROR**, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again, which requires a server restart. This setting provides backward compatibility with older versions of MySQL.

- `binlog_expire_logs_seconds`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-expire-logs-seconds=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_expire_logs_seconds</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.11)</td>
<td>2592000</td>
</tr>
<tr>
<td>Default Value (&lt;= 8.0.4)</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the binary log expiration period in seconds. After their expiration period ends, binary log files can be automatically removed. Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.4, “MySQL Server Logs”.

The default binary log expiration period is 2592000 seconds, which equals 30 days (30*24*60*60 seconds). The default applies if neither `binlog_expire_logs_seconds` nor the deprecated system variable `expire_logs_days` has a value set at startup. If a non-zero value for one of the variables `binlog_expire_logs_seconds` or `expire_logs_days` is set at startup, this value is used as the binary log expiration period. If a non-zero value for both of those variables is set at startup, the value for `binlog_expire_logs_seconds` is used as the binary log expiration period, and the value for `expire_logs_days` is ignored with a warning message.
To disable automatic purging of the binary log, specify a value of 0 explicitly for `binlog_expire_logs_seconds`, and do not specify a value for `expire_logs_days`. For compatibility with earlier releases, automatic purging is also disabled if you specify a value of 0 explicitly for `expire_logs_days` and do not specify a value for `binlog_expire_logs_seconds`. In that case, the default for `binlog_expire_logs_seconds` is not applied.

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

- `binlog_format`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-format=format</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ROW</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ROW</code>, <code>STATEMENT</code>, <code>MIXED</code></td>
</tr>
</tbody>
</table>

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Section 17.2.1, “Replication Formats”. `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

The default is `ROW`. Exception: In NDB Cluster, the default is `MIXED`; statement-based replication is not supported for NDB Cluster.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see Section 13.7.5.1, “SET Syntax for Variable Assignment”.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function.

For details of how stored programs (stored procedures and functions, triggers, and events) are handled when each binary logging format is set, see Section 24.7, “Binary Logging of Stored Programs”.

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If a session has open temporary tables, the replication format cannot be changed for the session (SET `@@SESSION.binlog_format`).
• If any replication channel has open temporary tables, the replication format cannot be changed globally (\texttt{SET @@GLOBAL.binlog\_format} or \texttt{SET @@PERSIST.binlog\_format}).

• If any replication channel applier thread is currently running, the replication format cannot be changed globally (\texttt{SET @@GLOBAL.binlog\_format} or \texttt{SET @@PERSIST.binlog\_format}).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use \texttt{PERSIST\_ONLY} (\texttt{SET @@PERSIST\_ONLY.binlog\_format}) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

Changing the logging format on a replication master does not cause a replication slave to change its logging format to match. Switching the replication format while replication is ongoing can cause issues if a replication slave has binary logging enabled, and the change results in the slave using \texttt{STATEMENT} format logging while the master is using \texttt{ROW} or \texttt{MIXED} format logging. A replication slave is not able to convert binary log entries received in \texttt{ROW} logging format to \texttt{STATEMENT} format for use in its own binary log, so this situation can cause replication to fail. For more information, see Section 5.4.4.2, "Setting The Binary Log Format".

The binary log format affects the behavior of the following server options:

• \texttt{--replicate-do-db}

• \texttt{--replicate-ignore-db}

• \texttt{--binlog-do-db}

• \texttt{--binlog-ignore-db}

These effects are discussed in detail in the descriptions of the individual options.

• \texttt{binlog\_group\_commit\_sync\_delay}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--binlog-group-commit-sync-delay=#}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{binlog_group_commit_sync_delay}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
</tbody>
</table>

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default \texttt{binlog_group_commit_sync_delay} is set to 0, meaning that there is no delay. Setting \texttt{binlog_group_commit_sync_delay} to a microsecond delay enables more transactions to
be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group.

When `sync_binlog=0` or `sync_binlog=1` is set, the delay specified by `binlog_group_commit_sync_delay` is applied for every binary log commit group before synchronization (or in the case of `sync_binlog=0`, before proceeding). When `sync_binlog` is set to a value $n$ greater than 1, the delay is applied after every $n$ binary log commit groups.

Setting `binlog_group_commit_sync_delay` can increase the number of parallel committing transactions on any server that has (or might have after a failover) a replication slave, and therefore can increase parallel execution on the replication slaves. To benefit from this effect, the slave servers must have `slave_parallel_type=LOGICAL_CLOCK` set, and the effect is more significant when `binlog_transaction_dependency_tracking=COMMIT_ORDER` is also set. It is important to take into account both the master's throughput and the slaves' throughput when you are tuning the setting for `binlog_group_commit_sync_delay`.

Setting `binlog_group_commit_sync_delay` can also reduce the number of `fsync()` calls to the binary log on any server (master or slave) that has a binary log.

Note that setting `binlog_group_commit_sync_delay` increases the latency of transactions on the server, which might affect client applications. Also, on highly concurrent workloads, it is possible for the delay to increase contention and therefore reduce throughput. Typically, the benefits of setting a delay outweigh the drawbacks, but tuning should always be carried out to determine the optimal setting.

- **`binlog_group_commit_sync_no_delay_count`**

<table>
<thead>
<tr>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
</tr>
<tr>
<td>System Variable</td>
</tr>
<tr>
<td>Scope</td>
</tr>
<tr>
<td>Dynamic</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default Value</td>
</tr>
<tr>
<td>Minimum Value</td>
</tr>
<tr>
<td>Maximum Value</td>
</tr>
</tbody>
</table>

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog_group_commit_sync_delay`. If `binlog_group_commit_sync_delay` is set to 0, then this option has no effect.

- **`binlog_max_flush_queue_time`**

<table>
<thead>
<tr>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
</tr>
<tr>
<td>System Variable</td>
</tr>
<tr>
<td>Scope</td>
</tr>
<tr>
<td>Dynamic</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100000</td>
</tr>
</tbody>
</table>

`binlog_max_flush_queue_time` is deprecated, and is marked for eventual removal in a future MySQL release. Formerly, this system variable controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. It no longer has any effect.

- **binlog_order_commits**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>binlog_order_commits</code></td>
</tr>
<tr>
<td>Scope</td>

</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

When this variable is enabled on a replication master (which is the default), transaction commit instructions issued to storage engines are serialized on a single thread, so that transactions are always committed in the same order as they are written to the binary log. Disabling this variable permits transaction commit instructions to be issued using multiple threads. Used in combination with binary log group commit, this prevents the commit rate of a single transaction being a bottleneck to throughput, and might therefore produce a performance improvement.

Transactions are written to the binary log at the point when all the storage engines involved have confirmed that the transaction is prepared to commit. The binary log group commit logic then commits a group of transactions after their binary log write has taken place. When `binlog_order_commits` is disabled, because multiple threads are used for this process, transactions in a commit group might be committed in a different order from their order in the binary log. (Transactions from a single client always commit in chronological order.) In many cases this does not matter, as operations carried out in separate transactions should produce consistent results, and if that is not the case, a single transaction ought to be used instead.

If you want to ensure that the transaction history on the master and on a multithreaded replication slave remains identical, set `slave_preserve_commit_order=1` on the replication slave.

- **binlog_rotate_encryption_master_key_at_startup**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-rotate-encryption-master-key-at-startup</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_rotate_encryption_master_key_at_startup</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Specifies whether or not the binary log master key is rotated at server startup. The binary log master key is the binary log encryption key that is used to encrypt file passwords for the binary log files and relay log files on the server. When a server is started for the first time with binary log encryption enabled (`binlog_encryption=ON`), a new binary log encryption key is generated and used as the binary log master key. If the `binlog_rotate_encryption_master_key_at_startup` system variable is also set to `ON`, whenever the server is restarted, a further binary log encryption key is generated and used as the binary log master key for all subsequent binary log files and relay log files. If the `binlog_rotate_encryption_master_key_at_startup` system variable is set to `OFF`, which is the default, the existing binary log master key is used again after the server restarts. For more information on binary log encryption keys and the binary log master key, see Section 17.3.10, “Encrypting Binary Log Files and Relay Log Files”.

- **binlog_row_event_max_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-event-max-size=#</code></td>
</tr>
<tr>

<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

When row-based binary logging is used, this setting is a soft limit on the maximum size of a row-based binary log event, in bytes. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded. The value must be (or else gets rounded down to) a multiple of 256. The default is 8192 bytes.

This global system variable is read-only and can be set only at server startup. Its value can therefore only be modified by using the `PERSIST_ONLY` keyword or the `@@persist_only` qualifier with the `SET` statement.

- **binlog_row_image**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-image=image_type</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_row_image</code></td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>full</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>full</code> (Log all columns)</td>
</tr>
<tr>
<td></td>
<td><code>minimal</code> (Log only changed columns, and</td>
</tr>
<tr>
<td></td>
<td>columns needed to identify rows)</td>
</tr>
<tr>
<td></td>
<td><code>noblob</code> (Log all columns, except for unneeded</td>
</tr>
<tr>
<td></td>
<td>BLOB and TEXT columns)</td>
</tr>
</tbody>
</table>

For MySQL row-based replication, this variable determines how row images are written to the binary log.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- **full**: Log all columns in both the before image and the after image.
- **minimal**: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image where a value was specified by the SQL statement, or generated by auto-increment.
- **noblob**: Log all columns (same as `full`), except for BLOB and TEXT columns that are not required to identify rows, or that have not changed.
Note
This variable is not supported by NDB Cluster; setting it has no effect on the logging of NDB tables.

The default value is **full**.

When using **minimal** or **noblob**, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is **STATEMENT**. When **binlog_format** is **MIXED**, the setting for **binlog_row_image** is applied to changes that are logged using row-based format, but this setting no effect on changes logged as statements.

Setting **binlog_row_image** on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- **binlog_row_metadata**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><strong>--binlog-row-metadata=metadata_type</strong></td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.1</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><strong>binlog_row_metadata</strong></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><strong>MINIMAL</strong></td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td><strong>FULL</strong> (All metadata is included.)</td>
</tr>
<tr>
<td></td>
<td><strong>MINIMAL</strong> (Limit included metadata.)</td>
</tr>
</tbody>
</table>

Configures the amount of table metadata added to the binary log when using row-based logging. When set to **MINIMAL**, the default, only metadata related to **SIGNED** flags, column character set and geometry types are logged. When set to **FULL** complete metadata for tables is logged, such as column name, **ENUM** or **SET** string values, **PRIMARY KEY** information, and so on.

The extended metadata serves the following purposes:
• Slaves use the metadata to transfer data when its table structure is different from the master’s.

• External software can use the metadata to decode row events and store the data into external databases, such as a data warehouse.

• `binlog_row_value_options`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-value-options=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_row_value_options</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td>''</td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>PARTIAL_JSON</code></td>
</tr>
</tbody>
</table>

When set to `PARTIAL_JSON`, this enables use of a space-efficient binary log format for updates that modify only a small portion of a JSON document, which causes row-based replication to write only the modified parts of the JSON document to the after-image for the update in the binary log (rather than writing the full document). This works for an `UPDATE` statement which modifies a JSON column using any sequence of `JSON_SET()`, `JSON_REPLACE()`, and `JSON_REMOVE()`. If the modification requires more space than the full document, or if the server is unable to generate a partial update, the full document is used instead.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

`PARTIAL_JSON` is the only supported value; to unset `binlog_row_value_options`, set its value to the empty string.

`binlog_row_value_options=PARTIAL_JSON` takes effect only when binary logging is enabled and `binlog_format` is set to `ROW` or `MIXED`. Statement-based replication `always` logs only the modified parts of the JSON document, regardless of any value set for `binlog_row_value_options`. To maximize the amount of space saved, use `binlog_row_image=NOBLOB` or `binlog_row_image=MINIMAL` together with this option. `binlog_row_image=FULL` saves less space than either of these, since the full JSON document is stored in the before-image, and the partial update is stored only in the after-image.

`binlog_row_value_options=PARTIAL_JSON` overrides any setting for the `log_bin_use_v1_row_events` variable. If that option is enabled, the event format required by `binlog_row_value_options=PARTIAL_JSON` is still used.

`mysqlbinlog` output includes partial JSON updates in the form of events encoded as base-64 strings using `BINLOG` statements. If the `--verbose` option is specified, `mysqlbinlog` displays the partial JSON updates as readable JSON using pseudo-SQL statements.

MySQL Replication generates an error if a modification cannot be applied to the JSON document on the slave. This includes a failure to find the path. Be aware that, even with this and other safety checks,
if a JSON document on a slave has diverged from that on the master and a partial update is applied, it remains theoretically possible to produce a valid but unexpected JSON document on the slave.

Replicating to older MySQL versions. When replicating to a slave that uses MySQL 8.0.2 or a previous version from a master running MySQL 8.0.3 or later, binlog_row_value_options must be disabled (that is, set to ''). This is because logging of JSON partial updates uses a binary log event type introduced in MySQL 8.0.3; this event type is not recognized by previous versions of MySQL.

• **binlog_rows_query_log_events**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--binlog-rows-query-log-events</td>
</tr>
<tr>
<td>System Variable</td>
<td>binlog_rows_query_log_events</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

The **binlog_rows_query_log_events** system variable affects row-based logging only. When enabled, it causes the MySQL Server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes; such as obtaining the original query issued on the master when it cannot be reconstructed from the row updates.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

These events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog's **--verbose** option twice, either as **-vv** or **--verbose --verbose**.

• **binlog_stmt_cache_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--binlog-stmt-cache-size=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>binlog_stmt_cache_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. When binary logging is enabled on the server (with the **log_bin** system variable set to ON), separate binary log transaction and statement caches are allocated for each
client if the server supports any transactional storage engines. If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, “The Binary Log”.

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `binlog_transaction_dependency_tracking`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-transaction-dependency-tracking=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_transaction_dependency_tracking</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>COMMIT_ORDER</td>
</tr>
<tr>
<td>Valid Values</td>
<td>COMMIT_ORDER, WRITESET, WRITESET_SESSION</td>
</tr>
</tbody>
</table>

The source of dependency information that the master uses to determine which transactions can be executed in parallel by the slave’s multithreaded applier. This variable can take one of the three values described in the following list:

- **COMMIT_ORDER**: Dependency information is generated from the master's commit timestamps. This is the default. This mode is also used for any transactions without write sets, even if this variable's value is `WRITESET` or `WRITESET_SESSION`; this is also the case for transactions updating tables without primary keys and transactions updating tables having foreign key constraints.

- **WRITESET**: Dependency information is generated from the master’s write set, and any transactions which write different tuples can be parallelized.

- **WRITESET_SESSION**: Dependency information is generated from the master’s write set, but no two updates from the same session can be reordered.

`WRITESET` and `WRITESET_SESSION` modes do not deliver any transaction dependencies that are newer than those that would have been returned in `COMMIT_ORDER` mode.

The value of this variable cannot be set to anything other than `COMMIT_ORDER` if `transaction_write_set_extraction` is `OFF`. You should also note that the value of `transaction_write_set_extraction` cannot be changed if the current value of `binlog_transaction_dependency_tracking` is `WRITESET` or `WRITESET_SESSION`.

The number of row hashes to be kept and checked for the latest transaction to have changed a given row is determined by the value of `binlog_transaction_dependency_history_size`.

- `binlog_transaction_dependency_history_size`
## Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--binlog-transaction-dependency-history-size=#</code></td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.1</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>binlog_transaction_dependency_history_size</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>25000</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>10000000</td>
</tr>
</tbody>
</table>

Sets an upper limit on the number of row hashes which are kept in memory and used for looking up the transaction that last modified a given row. Once this number of hashes has been reached, the history is purged.

- `expire_logs_days`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--expire-logs-days=#</code></td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>8.0.3</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>expire_logs_days</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value (&gt;= 8.0.11)</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Default Value (&gt;= 8.0.2, &lt;= 8.0.4)</strong></td>
<td>30</td>
</tr>
<tr>
<td><strong>Default Value (&lt;= 8.0.1)</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>99</td>
</tr>
</tbody>
</table>

Specifies the number of days before automatic removal of binary log files. `expire_logs_days` is deprecated, and will be removed in a future release. Instead, use `binlog_expire_logs_seconds`, which sets the binary log expiration period in seconds. If you do not set a value for either system variable, the default expiration period is 30 days. Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.4, “MySQL Server Logs”.

Any non-zero value that you specify for `expire_logs_days` is ignored if `binlog_expire_logs_seconds` is also specified, and the value of `binlog_expire_logs_seconds` is used instead as the binary log expiration period. A warning message is issued in this situation. A non-zero value for `expire_logs_days` is only applied as the binary log expiration period if `binlog_expire_logs_seconds` is not specified or is specified as 0.
To disable automatic purging of the binary log, specify a value of 0 explicitly for `binlog_expire_logs_seconds`, and do not specify a value for `expire_logs_days`. For compatibility with earlier releases, automatic purging is also disabled if you specify a value of 0 explicitly for `expire_logs_days` and do not specify a value for `binlog_expire_logs_seconds`. In that case, the default for `binlog_expire_logs_seconds` is not applied.

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

- **log_bin**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_bin</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Shows the status of binary logging on the server, either enabled (ON) or disabled (OFF). With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. ON means that the binary log is available, OFF means that it is not in use. The `--log-bin` option can be used to specify a base name and location for the binary log.

In earlier MySQL versions, binary logging was disabled by default, and was enabled if you specified the `--log-bin` option. From MySQL 8.0, binary logging is enabled by default, with the `log_bin` system variable set to ON, whether or not you specify the `--log-bin` option. The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default. It is possible to enable binary logging in this case by specifying the `--log-bin` option.

If the `--skip-log-bin` or `--disable-log-bin` option is specified at startup, binary logging is disabled, with the `log_bin` system variable set to OFF. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence.

For information on the format and management of the binary log, see Section 5.4.4, “The Binary Log”.

- **log_bin_basename**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_bin_basename</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
</tbody>
</table>

Holds the base name and path for the binary log files, which can be set with the `--log-bin` server option. In MySQL 8.0, if the `--log-bin` option is not supplied, the default base name is `binlog`. For compatibility with MySQL 5.7, if the `--log-bin` option is supplied with no string or with an empty string, the default base name is `host_name-bin`, using the name of the host machine. The default location is the data directory.
Replication and Binary Logging Options and Variables

- **log_bin_index**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_bin_index</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

Holds the base name and path for the binary log index file, which can be set with the `--log-bin-index` server option.

- **log_bin_trust_function_creators**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-bin-trust-function-creators</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>log_bin_trust_function_creators</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See Section 24.7, “Binary Logging of Stored Programs”.

- **log_bin_use_v1_row_events**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-bin-use-v1-row-events[={0</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_bin_use_v1_row_events</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Shows whether Version 2 binary logging is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.
This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of NDB Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB $EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

### Note
MySQL NDB Cluster 8.0 uses Version 2 binary log row events by default. You should keep this mind when planning upgrades or downgrades, and for setups using NDB Cluster Replication.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `log_builtin_as_identified_by_password`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>`--log-builtin-as-identified-by-password[={OFF</td>
</tr>
<tr>
<td><strong>Removed</strong></td>
<td>8.0.11</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_builtin_as_identified_by_password</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

This system variable was removed in MySQL 8.0.11.

- `log_slave_updates`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--log-slave-updates</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>log_slave_updates</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value (&gt;= 8.0.3)</strong></td>
<td>TRUE</td>
</tr>
<tr>
<td><strong>Default Value (&lt;= 8.0.2)</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Whether updates received by a slave server from a master server should be logged to the slave’s own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 17.1.6, “Replication and Binary Logging Options and Variables”.
This system variable is set on by default, and is read-only. If you need to prevent the slave server from logging updates, specify `--skip-log-slave-updates` when you start the slave, or specify `log_slave_updates=OFF` in the configuration file for the slave.

- **log_statements_unsafe_for_binlog**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>log_statements_unsafe_for_binlog</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

- **master_verify_checksum**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>master_verify_checksum</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enabling this variable causes the master to examine checksums when reading from the binary log. `master_verify_checksum` is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- **max_binlog_cache_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-binlog-cache-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_binlog_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

If a transaction requires more than this many bytes of memory, the server generates a **Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage** error. The minimum value is 4096. The maximum possible value is 16EiB (exbibytes). The
maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

max_binlog_cache_size sets the size for the transaction cache only; the upper limit for the statement cache is governed by the max_binlog_stmt_cache_size system variable.

The visibility to sessions of max_binlog_cache_size matches that of the binlog_cache_size system variable; in other words, changing its value affects only new sessions that are started after the value is changed.

- **max_binlog_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-binlog-size=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>max_binlog_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB. Encrypted binary log files have an additional 512-byte header, which is included in max_binlog_size.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than max_binlog_size.

If max_relay_log_size is 0, the value of max_binlog_size applies to relay logs as well.

With GTIDs in use on the server, when max_binlog_size is reached, if the system table mysql.gtid_executed cannot be accessed to write the GTIDs from the current binary log file, the binary log cannot be rotated. In this situation, the server responds according to its binlog_error_action setting. If IGNORE_ERROR is set, an error is logged on the server and binary logging is halted, or if ABORT_SERVER is set, the server shuts down.

- **max_binlog_stmt_cache_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-binlog-stmt-cache-size=#</td>
</tr>
<tr>
<td>System Variable</td>

<td>18446744073709547520</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709547520</td>
</tr>
</tbody>
</table>

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `original_commit_timestamp`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>original_commit_timestamp</code></td>
</tr>
<tr>

<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
</tbody>
</table>

For internal use by replication. When re-executing a transaction on a slave, this is set to the time when the transaction was committed on the original master, measured in microseconds since the epoch. This allows the original commit timestamp to be propagated throughout a replication topology.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

- `sql_log_bin`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sql_log_bin</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the master you do not want replicated to the slave.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.
Setting this variable to OFF prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

- **sync_binlog**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sync-binlog=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>sync_binlog</code></td>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Controls how often the MySQL server synchronizes the binary log to disk.

- **sync_binlog=0**: Disables synchronization of the binary log to disk by the MySQL server. Instead, the MySQL server relies on the operating system to flush the binary log to disk from time to time as it does for any other file. This setting provides the best performance, but in the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been synchronized to the binary log.

- **sync_binlog=1**: Enables synchronization of the binary log to disk before transactions are committed. This is the safest setting but can have a negative impact on performance due to the increased number of disk writes. In the event of a power failure or operating system crash, transactions that are missing from the binary log are only in a prepared state. This permits the automatic recovery routine to roll back the transactions, which guarantees that no transaction is lost from the binary log.

- **sync_binlog=N**, where N is a value other than 0 or 1: The binary log is synchronized to disk after N binary log commit groups have been collected. In the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been flushed to the binary log. This setting can have a negative impact on performance due to the increased number of disk writes. A higher value improves performance, but with an increased risk of data loss.

For the greatest possible durability and consistency in a replication setup that uses InnoDB with transactions, use these settings:

- `sync_binlog=1`.
- `innodb_flush_log_at_trx_commit=1`.

**Caution**

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the...
recommended settings, and in the worst case, a power outage can corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- **transaction_write_set_extraction**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--transaction-write-set-extraction=[value]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>transaction_write_set_extraction</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value (&gt;= 8.0.2)</td>
<td><code>XXHASH64</code></td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>OFF</code></td>
</tr>
<tr>
<td></td>
<td><code>MURMUR32</code></td>
</tr>
<tr>
<td></td>
<td><code>XXHASH64</code></td>
</tr>
</tbody>
</table>

Defines the algorithm used to hash the writes extracted during a transaction. If you are using Group Replication, this variable must be set to `XXHASH64` because the process of extracting the writes from a transaction is required for conflict detection on all group members. See Section 18.8.1, “Group Replication Requirements”.

As of MySQL 8.0.14, setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

**Note**

The value of this variable cannot be changed when `binlog_transaction_dependency_tracking` is set to either of WRITESET or WRITESET_SESSION.

### 17.1.6.5 Global Transaction ID Options and Variables

- **Startup Options Used with GTID Replication**
- **System Variables Used with GTID Replication**

The MySQL Server options and system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs).

For additional information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

**Startup Options Used with GTID Replication**

The following server startup options are used with GTID-based replication:

- `--enforce-gtid-consistency`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--enforce-gtid-consistency=[value]</td>
</tr>
<tr>
<td>System Variable</td>
<td>enforce_gtid_consistency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, ON, WARN</td>
</tr>
</tbody>
</table>

When enabled, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You must set this option to ON before enabling GTID based replication.

The values that --enforce-gtid-consistency can be configured to are:

- **OFF**: all transactions are allowed to violate GTID consistency.
- **ON**: no transaction is allowed to violate GTID consistency.
- **WARN**: all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

Setting --enforce-gtid-consistency without a value is an alias for --enforce-gtid-consistency=ON. This impacts on the behavior of the variable, see enforce_gtid_consistency.

Only statements that can be logged using GTID safe statements can be logged when enforce-gtid-consistency is set to ON, so the operations listed here cannot be used with this option:

- **CREATE TABLE ... SELECT** statements
- **CREATE TEMPORARY TABLE** or **DROP TEMPORARY TABLE** statements inside transactions
- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all nontransactional tables are temporary.

--enforce-gtid-consistency only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For more information, see Section 17.1.3.6, “Restrictions on Replication with GTIDs”.

- --executed-gtids-compression-period

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--executed-gtids-compression-period=#</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1000</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- **--gtid-mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--gtid-mode=MODE</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>gtid_mode</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>OFF</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td><code>OFF_PERMISSIVE</code></td>
</tr>
<tr>
<td></td>
<td><code>ON_PERMISSIVE</code></td>
</tr>
<tr>
<td></td>
<td><code>ON</code></td>
</tr>
</tbody>
</table>

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Setting this option to `--gtid-mode=ON` requires that `enforce-gtid-consistency` be set to `ON`. The `gtid_mode` variable is dynamic and enables GTID based replication to be configured online. Before using this feature, see Section 17.1.5, “Changing Replication Modes on Online Servers”.

- **--gtid-executed-compression-period**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--gtid-executed-compression-period=#</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1000</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Compress the `mysql.gtid_executed` table each time this many transactions have taken place. A setting of 0 means that this table is not compressed. No compression of the table occurs when binary logging is enabled, therefore the option has no effect unless `log_bin` is `OFF`.

See `mysql.gtid_executed Table Compression`, for more information.
System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-gtid-simple-recovery</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_gtid_simple_recovery</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts.

When `binlog_gtid_simple_recovery=FALSE`, the method of iterating the binary log files is:

- To initialize `gtid_executed`, binary log files are iterated from the newest file, stopping at the first binary log that has any `Previous_gtid_log_event`. All GTIDs from `Previous_gtid_log_event` and `Gtid_log_events` are read from this binary log file. This GTID set is stored internally and called `gtids_in_binlog`. The value of `gtid_executed` is computed as the union of this set and the GTIDs stored in the `mysql.gtid_executed` table.

  This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

- To initialize `gtid_purged`, binary log files are iterated from the oldest to the newest, stopping at the first binary log that contains either a `Previous_gtid_log_event` that is non-empty (that has at least one GTID) or that has at least one `Gtid_log_event`. From this binary log it reads `Previous_gtid_log_event`. This GTID set is subtracted from `gtids_in_binlog` and the result stored in the internal variable `gtids_in_binlog_not_purged`. The value of `gtid_purged` is initialized to the value of `gtid_executed`, minus `gtids_in_binlog_not_purged`.

When `binlog_gtid_simple_recovery=TRUE`, which is the default, the server iterates only the oldest and the newest binary log files and the values of `gtid_purged` and `gtid_executed` are computed based only on `Previous_gtid_log_event` or `Gtid_log_event` found in these files. This ensures only two binary log files are iterated during server restart or when binary logs are being purged.

Note

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- The newest binary log was generated by MySQL 5.7.5 or older, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.

- A `SET GTID_PURGED` statement was issued on a MySQL version prior to 5.7.7, and the binary log that was active at the time of the `SET GTID_PURGED` has not yet been purged.
If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

If you are using MySQL 5.7.7 or earlier, after issuing a `SET gtid_purged` statement note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=FALSE` to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

- **enforce_gtid_consistency**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--enforce-gtid-consistency[=value]</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>enforce_gtid_consistency</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>OFF</code>, <code>ON</code>, <code>WARN</code></td>
</tr>
</tbody>
</table>

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You must set this variable to `ON` before enabling GTID based replication.

The values that `enforce_gtid_consistency` can be configured to are:

- **OFF**: all transactions are allowed to violate GTID consistency.
- **ON**: no transaction is allowed to violate GTID consistency.
- **WARN**: all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

`enforce_gtid_consistency` only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For more information on statements that can be logged using GTID based replication, see `--enforce-gtid-consistency`.

Prior to MySQL 5.7 and in early releases in that release series, the boolean `enforce_gtid_consistency` defaulted to `OFF`. To maintain compatibility with these earlier releases, the enumeration defaults to `OFF`, and setting `--enforce-gtid-consistency` without a value is interpreted as setting the value to `ON`. The variable also has multiple textual aliases for the values: 0=OFF=FALSE, 1=ON=TRUE, 2=WARN. This differs from other enumeration types but maintains compatibility with the boolean type used in previous releases. These changes impact on what is returned by the variable. Using `SELECT @@ENFORCE_GTID_CONSISTENCY, SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY', and SELECT * FROM INFORMATION_SCHEMA.VARIABLES`
WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY', all return the textual form, not the numeric form. This is an incompatible change, since @@ENFORCE_GTID_CONSISTENCY returns the numeric form for booleans but returns the textual form for SHOW and the Information Schema.

• executed_gtids_compression_period

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>executed_gtids_compression_period</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option is deprecated and will be removed in a future MySQL release. Use the renamed gtid_executed_compression_period to control how the gtid_executed table is compressed.

• gtid_executed

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>gtid_executed</td>
</tr>
<tr>
<td>System Variable</td>
<td>gtid_executed</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a SET gtid_purged statement. This is the same as the value of the Executed_Gtid_Set column in the output of SHOW MASTER STATUS and SHOW SLAVE STATUS. The value of this variable is a GTID set, see GTID Sets for more information.

When the server starts, @@GLOBAL.gtid_executed is initialized. See binlog_gtid_simple_recovery for more information on how binary logs are iterated to populate gtid_executed. GTIDs are then added to the set as transactions are executed, or if any SET gtid_purged statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to GTID_SUBTRACT(@@GLOBAL.gtid_executed, @@GLOBAL.gtid_purged); that is, to all transactions in the binary log that have not yet been purged.
Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

In some older releases, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope is now deprecated.

- `gtid_executed_compression_period`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>gtid_executed_compression_period</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. A setting of 0 means that this table is not compressed. Since no compression of the table occurs when using the binary log, setting the value of the variable has no effect unless binary logging is disabled.

See `mysql.gtid_executed Table Compression`, for more information.

- `gtid_mode`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>gtid_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>OFF</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>OFF</code> <code>OFF_PERMISSIVE</code> <code>ON_PERMISSIVE</code> <code>ON</code></td>
</tr>
</tbody>
</table>

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. You must have privileges sufficient to set global system variables. See Section 5.1.9.1, “System Variable Privileges”. `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see Section 17.1.5, “Changing Replication Modes on Online Servers”.
Logged transactions can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have a unique identifier that is used to refer to transactions. The different modes are:

- **OFF**: Both new and replicated transactions must be anonymous.
- **OFF_PERMISSIVE**: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- **ON_PERMISSIVE**: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- **ON**: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to **OFF_PERMISSIVE**, it is possible to change to **OFF** or **ON_PERMISSIVE** but not to **ON**.

The values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values.

- **gtid_next**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>gtid_next</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td><strong>AUTOMATIC</strong></td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td><strong>AUTOMATIC</strong></td>
</tr>
<tr>
<td></td>
<td><strong>ANONYMOUS</strong></td>
</tr>
<tr>
<td></td>
<td><strong>UUID:NUMBER</strong></td>
</tr>
</tbody>
</table>

This variable is used to specify whether and how the next GTID is obtained.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.9.1, “System Variable Privileges”.

`gtid_next` can take any of the following values:

- **AUTOMATIC**: Use the next automatically-generated global transaction ID.
- **ANONYMOUS**: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in **UUID:NUMBER** format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see Section 17.1.5.1, “Replication Mode Concepts” for more information. Setting this variable has no effect if `gtid_mode` is **OFF**.
After this variable has been set to `UUID:NUMBER`, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

`DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines.

- **gtid-owned**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>gtid_owned</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

- **gtid_purged**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>gtid_purged</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in **gtid_executed**. The value of this variable is a GTID set, see **GTID Sets** for more information.

When the server starts, the global value of **gtid_purged** is initialized to a set of GTIDs. See `binlog_gtid_simple_recovery` for more information on how binary logs are iterated to populate **gtid_purged**. Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

There are two ways to set *gtid_purged*. When *gtid_set* is a superset of *gtid_purged*, and does not intersect with \( gtid\_subtract(gtid\_executed - gtid\_purged) \), use:

```sql
SET @@GLOBAL.GTID_PURGED = 'gtid_set'
```

The result is that **GTID_PURGED** is set equal to *gtid_set*, and **GTID_EXECUTED** becomes the union of *gtid_set* and the previous value of **GTID_EXECUTED**.

When *gtid_set* does not intersect with *gtid_executed* use:

```sql
SET @@GLOBAL.GTID_PURGED = '+gtid_set'
```

The result is that *gtid_set* is added to both **gtid_executed** and **gtid_purged**.
If binary logs from MySQL 5.7.7 or earlier exist, there is a chance that `gtid_purged` may be computed incorrectly with `binlog_gtid_simple_recovery=TRUE`. See `binlog_gtid_simple_recovery` for more information.

- `simplified_binlog_gtid_recovery`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--simplified-binlog-gtid-recovery</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>simplified_binlog_gtid_recovery</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option is deprecated and will be removed in a future MySQL release. Use the renamed `binlog_gtid_simple_recovery` to control how MySQL iterates through binary log files after a crash.

### 17.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a slave.

#### 17.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master.

The `SHOW SLAVE STATUS` statement, which you must execute on each slave, provides information about the configuration and status of the connection between the slave server and the master server. From MySQL 5.7, the Performance Schema has replication tables that provide this information in a more accessible form. See Section 26.12.11, “Performance Schema Replication Tables”.

The `SHOW STATUS` statement also provided some information relating specifically to replication slaves. From MySQL 5.7, the following status variables previously monitored using `SHOW STATUS` were deprecated and moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`
- `Slave_heartbeat_period`
- `Slave_running`

The replication heartbeat information shown in the Performance Schema replication tables lets you check that the replication connection is active even if the master has not sent events to the slave recently. The master sends a heartbeat signal to a slave if there are no updates to, and no unsent events in, the binary log for a longer period than the heartbeat interval. The `MASTER_HEARTBEAT_PERIOD` setting on the master (set by the `CHANGE MASTER TO` statement) specifies the frequency of the heartbeat.
which defaults to half of the connection timeout interval for the slave (\texttt{slave_net_timeout}). The \texttt{replication_connection_status} Performance Schema table shows when the most recent heartbeat signal was received by a replication slave, and how many heartbeat signals it has received.

If you are using the \texttt{SHOW SLAVE STATUS} statement to check on the status of an individual slave, the statement provides the following information:

```
mysql> SHOW SLAVE STATUS|
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
Master_Host: master1
Master_User: root
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: slave1-relay-bin.000056
Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error: 
Skip_Counter: 0
Exec_Master_Log_Pos: 931
Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File: 
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_CIPHER:
Master_SSL_Key:
Seconds_Behind_Master: 0
Master_SSL_VERIFY_SERVER_CERT: No
Last_IO_Enrrno: 0
Last_IO_Error: 
Last_SQL_Enrrno: 0
Last_SQL_Error: 
Replicate_Ignore_Server_Ids: 0
```

The key fields from the status report to examine are:

- **Slave.IO.Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be \texttt{Yes} unless you have not yet started replication or have explicitly stopped it with \texttt{STOP SLAVE}.

- **Slave.SQL.Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be \texttt{Yes}.

- **Last.IO.Error, Last.SQL.Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
• **Seconds_Behind_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds_Behind_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave_net_timeout** has not yet elapsed.

It is also possible that transient values for **Seconds_Behind_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds_Behind_Master** displays 0; but when the slave I/O thread is still queuing up a new event, **Seconds_Behind_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute **SHOW SLAVE STATUS** several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

• (**Master_Log_file**, **Read_Master_Log_Pos**): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.

• (**Relay_Master_Log_File**, **Exec_Master_Log_Pos**): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.

• (**Relay_Log_File**, **Relay_Log_Pos**): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using **SHOW PROCESSLIST** to examine the list of running processes. Slave connections have **Binlog Dump** in the **Command** field:

```sql
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
    Id: 10
    User: root
    Host: slave1:58371
db: NULL
    Command: Binlog Dump
    Time: 777
    State: Has sent all binlog to slave; waiting for binlog to be updated
    Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the **--report-host** option and are connected to the master, the **SHOW SLAVE HOSTS** statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the **--report-host** option, the connecting port, and master ID:

```sql
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+-------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
|-----------+--------+------|-------------------+-----------+
|        10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+------|-------------------+-----------+
1 row in set (0.00 sec)
```
17.1.7.2 Pausing Replication on the Slave

You can stop and start replication on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

17.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process as will without affecting the ability to update to the latest database status on either the master or slave side.
Replication Formats

For more information on the specifics of the replication implementation, see Section 17.2.2, “Replication Implementation Details”.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, “Examining Thread Information”, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 17.2.4, “Replication Relay and Status Logs”.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”.

17.2.1 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

• When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called statement-based replication (which can be abbreviated as SBR), which corresponds to the MySQL statement-based binary logging format.

• When using row-based logging, the master writes events to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called row-based replication (which can be abbreviated as RBR).

Row-based logging is the default method.

• You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called mixed-format logging. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is referred to as mixed-based replication or mixed-format replication. For more information, see Section 5.4.4.3, “Mixed Binary Logging Format”.

NDB Cluster. The default binary logging format in MySQL NDB Cluster 8.0 is MIXED. You should note that NDB Cluster Replication always uses row-based replication, and that the NDB storage engine is incompatible with statement-based replication. See Section 22.6.2, “General Requirements for NDB Cluster Replication”, for more information.

When using MIXED format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.4.4.3, “Mixed Binary Logging Format”.

The logging format in a running MySQL server is controlled by setting the binlog_format server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables. Setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions. Setting the variable globally takes effect for clients that connect after the change, but not for any current
client sessions, including the session where the variable setting was changed. To make the global system variable setting permanent so that it applies across server restarts, you must set it in an option file. For more information, see Section 13.7.5.1, “SET Syntax for Variable Assignment”.

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.4.4.2, “Setting The Binary Log Format”.

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See Section 5.1.9.1, “System Variable Privileges”.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 24.7, “Binary Logging of Stored Programs”.

17.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- Advantages of statement-based replication
- Disadvantages of statement-based replication
- Advantages of row-based replication
- Disadvantages of row-based replication

Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in much less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.** Not all statements which modify data (such as `INSERT`, `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See Section 17.4.1.16, “Replication of Invoked Features”, for more information.
• **DELETE** and **UPDATE** statements that use a **LIMIT** clause without an **ORDER BY** are nondeterministic. See [Section 17.4.1.18, “Replication and LIMIT”](#).

• Locking read statements (**SELECT ... FOR UPDATE** and **SELECT ... FOR SHARE**) that use **NOWAIT** or **SKIP LOCKED** options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

• Deterministic UDFs must be applied on the slaves.

• Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - **LOAD_FILE()**
  - **UUID(), UUID_SHORT()**
  - **USER()**
  - **FOUND_ROWS()**
  - **SYSDATE()** (unless both the master and the slave are started with the **--sysdate-is-now** option)
  - **GET_LOCK()**
  - **IS_FREE_LOCK()**
  - **IS_USED_LOCK()**
  - **MASTER_POS_WAIT()**
  - **RAND()**
  - **RELEASE_LOCK()**
  - **SLEEP()**
  - **VERSION()**

However, all other functions are replicated correctly using statement-based replication, including **NOW()** and so forth.

For more information, see [Section 17.4.1.14, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using **SHOW WARNINGS**.

• **INSERT ... SELECT** requires a greater number of row-level locks than with row-based replication.

• **UPDATE** statements that require a table scan (because no index is used in the **WHERE** clause) must lock a greater number of rows than with row-based replication.

• For **InnoDB**: An **INSERT** statement that uses **AUTO_INCREMENT** blocks other nonconflicting **INSERT** statements.
Replication Formats

- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.

- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 17.4.1.28, “Slave Errors During Replication”.

- Stored functions execute with the same NOW() value as the calling statement. However, this is not true of stored procedures.

- Deterministic UDFs must be applied on the slaves.

- Table definitions must be (nearly) identical on master and slave. See Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”, for more information.

Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

  **Note**

  Statements that update the information in the mysql database—such as GRANT, REVOKE and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

  For statements such as CREATE TABLE ... SELECT, a CREATE statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - INSERT ... SELECT
  - INSERT statements with AUTO_INCREMENT
  - UPDATE or DELETE statements with WHERE clauses that do not use keys or do not change most of the examined rows.

- Fewer row locks are required on the slave for any INSERT, UPDATE, or DELETE statement.

Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an UPDATE or DELETE statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use binlog_row_image=minimal to reduce the disadvantage considerably.

- Deterministic UDFs that generate large BLOB values take longer to replicate with row-based replication than with statement-based replication. This is because the BLOB column value is logged, rather than the statement generating the data.
• You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `--vv` option is used.

• For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

17.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see Section 17.2.1, “Replication Formats”, and Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

For information about issues specific to NDB Cluster Replication (which depends on row-based replication), see Section 22.6.3, “Known Issues in NDB Cluster Replication”.

• **Row-based logging of temporary tables.** As noted in Section 17.4.1.30, “Replication and Temporary Tables”, temporary tables are not replicated when using row-based format or (from MySQL 8.0.4) mixed format. For more information, see Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

Temporary tables are not replicated when using row-based or mixed format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

You can switch from statement-based to row-based binary logging format at runtime even when temporary tables have been created. However, in MySQL 8.0, you cannot switch from row-based or mixed format for binary logging to statement-based format at runtime, because any `CREATE TEMPORARY TABLE` statements will have been omitted from the binary log in the previous mode.

The MySQL server tracks the logging mode that was in effect when each temporary table was created. When a given client session ends, the server logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists and was created when statement-based binary logging was in use. If row-based or mixed format binary logging was in use when the table was created, the `DROP TEMPORARY TABLE IF EXISTS` statement is not logged. In releases before MySQL 8.0.4 and 5.7.25, the `DROP TEMPORARY TABLE IF EXISTS` statement was logged regardless of the logging mode that was in effect.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

• **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows
Replication Formats

are applied in batch mode. Depending on the engine used for the slave’s copy of the table, this may or may not be effective.

- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see Section 13.7.7.1, “BINLOG Syntax”). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see Section 4.6.8.2, “mysqlbinlog Row Event Display”.

- **Binary log execution errors and slave_exec_mode.** Using `slave_exec_mode=IDEMPOTENT` is generally only useful with MySQL NDB Cluster replication, for which `IDEMPOTENT` is the default value. (See Section 22.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”). When `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see Section 5.1.8, “Server System Variables”.

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than NDB.

- **Filtering based on server ID not supported.** You can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats, but is deprecated for use when `GTID_MODE=ON` is set. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.

- **Database-level replication options.** The effects of the `--replicate-do-db, --replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as InnoDB for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

### 17.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL replication refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as **safe**; otherwise, we refer to it as **unsafe**.
In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are not considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 17.4.1.12, “Replication and Floating-Point Values”).

Handling of safe and unsafe statements. A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of \texttt{binlog_format}).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. If a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL has a warning suppression mechanism. Whenever the 50 most recent \texttt{ER BINLOG UNSAFE STATEMENT} warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note \texttt{The last warning was repeated \textit{N} times in last \textit{S} seconds} is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see Section 17.2.1, “Replication Formats”.

Statements considered unsafe. Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on the slave.** These functions include \texttt{FOUND_ROWS()}, \texttt{GET_LOCK()}, \texttt{IS_FREE_LOCK()}, \texttt{IS_USED_LOCK()}, \texttt{LOAD_FILE()}, \texttt{MASTER_POS_WAIT()}, \texttt{RAND()}, \texttt{RELEASE_LOCK()}, \texttt{ROW_COUNT()}, \texttt{SESSION_USER()}, \texttt{SLEEP()}, \texttt{SYSDATE()}, \texttt{SYSTEM_USER()}, \texttt{USER()}, \texttt{UUID()}, and \texttt{UUID_SHORT()}.

- **Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: \texttt{CONNECTION_ID()}, \texttt{CURDATE()}, \texttt{CURRENT_DATE()}, \texttt{CURRENT_TIME()}, \texttt{CUR_TIMESTAMP()}, \texttt{CURTIME()}, \texttt{LAST_INSERT_ID()}, \texttt{LOCALTIME()}, \texttt{LOCALTIMESTAMP()}, \texttt{NOW()}, \texttt{UNIX_TIMESTAMP()}, \texttt{UTC_DATE()}, \texttt{UTC_TIME()}, and \texttt{UTC_TIMESTAMP()}.

For more information, see Section 17.4.1.14, “Replication and System Functions”.

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See Section 17.4.1.38, “Replication and Variables”. For exceptions, see Section 5.4.4.3, “Mixed Binary Logging Format”.

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL.
Replication Formats

- **Trigger or stored program updates a table having an AUTO_INCREMENT column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

  In addition, an `INSERT` into a table that has a composite primary key containing an AUTO_INCREMENT column that is not the first column of this composite key is unsafe.

  For more information, see Section 17.4.1.1, “Replication and AUTO_INCREMENT”.

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  An INSERT ... ON DUPLICATE KEY UPDATE statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See Section 17.4.1.18, “Replication and LIMIT”.

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.

- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Section 17.4.1.34, “Replication and Transactions”.

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **LOAD DATA statements.** LOAD DATA is treated as unsafe and when `binlog_format=MIXED` the statement is logged in row-based format. When `binlog_format=STATEMENT` LOAD DATA does not generate a warning, unlike other unsafe statements.

- **XA transactions.** If two XA transactions committed in parallel on the master are being prepared on the slave in the inverse order, locking dependencies can occur with statement-based replication that cannot be safely resolved, and it is possible for replication to fail with deadlock on the slave. When `binlog_format=STATEMENT` is set, DML statements inside XA transactions are flagged as being unsafe and generate a warning. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

- **DEFAULT clause that refers to a nondeterministic function.** If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as `INSERT`, `UPDATE`, and `ALTER TABLE`. Unlike most other unsafe statements, this category of statement cannot be replicated safely in row-based format. When `binlog_format` is set to `STATEMENT`, the statement is logged and executed but a warning message is written to the error log. When `binlog_format` is set to `MIXED` or `ROW`, the statement is not executed and an error message is written to the error log. For more information on the handling of explicit defaults, see Handling of Explicit Defaults as of MySQL 8.0.13.

  For additional information, see Section 17.4.1, “Replication Features and Issues”.

3174
17.2.2 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the **Binlog Dump** thread.

  The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

  The slave I/O thread reads the updates that the master's Binlog Dump thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

  The state of this thread is shown as **Slave_IO_running** in the output of `SHOW SLAVE STATUS` or as **Slave_running** in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 8.14.3, “Replication Master Thread States”. For slave states, see Section 8.14.4, “Replication Slave I/O Thread States”, and Section 8.14.5, “Replication Slave SQL Thread States”.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 2
    User: root
    Host: localhost:32931
    db: NULL
  Command: Binlog Dump
        Time: 94
    State: Has sent all binlog to slave; waiting for binlog to
           be updated
       Info: NULL
```
Here, thread 2 is a Binlog Dump replication thread that services a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from SHOW PROCESSLIST looks like this:

```sql
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 10
   User: system user
    Host: 
   Command: Connect
    Time: 11
   State: Waiting for master to send event
    Info: NULL
*************************** 2. row ***************************
    Id: 11
   User: system user
    Host: 
   Command: Connect
    Time: 11
   State: Has read all relay log; waiting for the slave I/O thread to update it
    Info: NULL
```

The State information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that SHOW PROCESSLIST was run, both threads were idle, waiting for further updates.

The value in the Time column can show how late the slave is compared to the master. See Section A.13, "MySQL 8.0 FAQ: Replication". If sufficient time elapses on the master side without activity on the Binlog Dump thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of net_write_timeout and net_retry_count; for more information about these, see Section 5.1.8, "Server System Variables".

The SHOW SLAVE STATUS statement provides additional information about replication processing on a slave server. See Section 17.1.7.1, "Checking Replication Status".

### 17.2.3 Replication Channels

Replication channels represent the path of transactions flowing from a master to a slave. This section describes how channels can be used in a replication topology, and the impact they have on single-source replication.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string ("""). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older slaves function as expected (see Section 17.2.3.2, "Compatibility with Previous Replication Statements"). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

A replication channel encompasses the path of transactions transmitted from a master to a slave. In multi-source replication a slave opens multiple channels, one per master, and each channel has its own relay log and applier (SQL) threads. Once transactions are received by a replication channel's receiver (I/O)
thread, they are added to the channel’s relay log file and passed through to an applier thread. This enables channels to function independently.

A replication channel is also associated with a host name and port. You can assign multiple channels to the same combination of host name and port. In MySQL 8.0, the maximum number of channels that can be added to one slave in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name (see Section 17.2.3.4, “Replication Channel Naming Conventions”). Channels can be configured independently.

**17.2.3.1 Commands for Operations on a Single Channel**

To enable MySQL replication operations to act on individual replication channels, use the `FOR CHANNEL channel` clause with the following replication statements:

- `CHANGE MASTER TO`
- `START SLAVE`
- `STOP SLAVE`
- `SHOW RELAYLOG EVENTS`
- `FLUSH RELAY LOGS`
- `SHOW SLAVE STATUS`
- `RESET SLAVE`

Similarly, an additional `channel` parameter is introduced for the following functions:

- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`

The following statements are disallowed for the `group_replication_recovery` channel:

- `START SLAVE`
- `STOP SLAVE`

The following statements are disallowed for the `group_replication_applier` channel:

- `START SLAVE`
- `STOP SLAVE`
- `SHOW SLAVE STATUS`
- `FLUSH RELAY LOGS`

**17.2.3.2 Compatibility with Previous Replication Statements**

When a replication slave has multiple channels and a `FOR CHANNEL channel` option is not specified, a valid statement generally acts on all available channels, with some specific exceptions.

For example, the following statements behave as expected for all except certain Group Replication channels:

- `START SLAVE` starts replication threads for all channels, except the `group_replication_recovery` and `group_replication_applier` channels.
• **STOP SLAVE** stops replication threads for all channels, except the `group_replication_recovery` and `group_replication_applier` channels.

• **SHOW SLAVE STATUS** reports the status for all channels, except the `group_replication_applier` channel.

• **FLUSH RELAY LOGS** flushes the relay logs for all channels, except the `group_replication_applier` channel.

• **RESET SLAVE** resets all channels.

**Warning**

Use **RESET SLAVE** with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 *Multiple channels exist on the slave. Please provide channel name as an argument.* is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel` option is not used to specify which channel to act on:

• **SHOW RELAYLOG EVENTS**

• **CHANGE MASTER TO**

• **MASTER_POS_WAIT()**

• **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()**

• **WAIT_FOR_EXECUTED_GTID_SET()**

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

### 17.2.3.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options *must* be configured correctly to use multi-source replication.

• **--relay-log-info-repository**

  This must be set to **TABLE**. If this option is set to **FILE**, attempting to add more sources to a slave fails with **ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY**. The **FILE** setting is now deprecated, and **TABLE** is the default.

• **--master-info-repository**

  This must be set to **TABLE**. If this option is set to **FILE**, attempting to add more sources to a slave fails with **ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY**. The **FILE** setting is now deprecated, and **TABLE** is the default.

The following startup options now affect **all** channels in a replication topology.

• **--log-slave-updates**

  All transactions received by the slave (even from multiple sources) are written in the binary log.

• **--relay-log-purge**
When set, each channel purges its own relay log automatically.

- **--slave_transaction_retries**
  The specified number of transaction retries can take place on all applier threads of all channels.

- **--skip-slave-start**
  No replication threads start on any channels.

- **--slave-skip-errors**
  Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are *mysqld* startup options, they are applied on every channel.

- **--max-relay-log-size=size**
  Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- **--relay-log-space-limit=size**
  Upper limit for the total size of all relay logs combined, for each individual channel. For \( N \) channels, the combined size of these logs is limited to \( \text{relay_log_space_limit} \times N \).

- **--slave-parallel-workers=value**
  Number of slave parallel workers per channel.

- **--slave-checkpoint-group**
  Waiting time by an I/O thread for each source.

- **--relay-log-index=filename**
  Base name for each channel’s relay log index file. See Section 17.2.3.4, “Replication Channel Naming Conventions”.

- **--relay-log=filename**
  Denotes the base name of each channel’s relay log file. See Section 17.2.3.4, “Replication Channel Naming Conventions”.

- **--slave_net-timeout=N**
  This value is set per channel, so that each channel waits for \( N \) seconds to check for a broken connection.

- **--slave-skip-counter=N**
  This value is set per channel, so that each channel skips \( N \) events from its master.

### 17.2.3.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case insensitive. Because channel names are used in slave tables, the character set used for these is
Replication Relay and Status Logs

always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replication slave. The relay log files and index files for each channel are named `relay_log_basename-channel.xxxxxx`, where `relay_log_basename` is a base name specified using the `--relay-log` option, and `channel` is the name of the channel logged to this file. If you do not specify the `--relay-log` option, a default file name is used that also includes the name of the channel.

17.2.4 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The **relay log** consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.

- The **master info log** contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log. The master info log is written to the `mysql.slave_master_info` table.

- The **relay log info log** holds status information about the execution point within the slave's relay log. The relay log is written to the `mysql.slave_relay_log_info` table.

In MySQL 8.0, a warning is given when `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

In MySQL 8.0, execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

---

**Important**

Do not attempt to update or insert rows in the `slave_master_info` or `slave_relay_log_info` tables manually. Doing so can cause undefined behavior, and is not supported.

**Making replication resilient to unexpected halts.** The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine InnoDB. Updates to the relay log info log table are committed together with the transactions, meaning that the slave's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the slave to guarantee resilience. For more details, see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”.

17.2.4.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files. The default location for relay log files is the data directory.
The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using mysqlbinlog (see Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files").

For the default replication channel, relay log file names have the default form host_name-relay-bin.nnnnnn, where host_name is the name of the slave server host and nnnnnn is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with 000001. For non-default replication channels, the default base name is host_name-relay-bin-channel, where channel is the name of the replication channel recorded in the relay log.

The slave uses an index file to track the relay log files currently in use. The default relay log index file name is host_name-relay-bin.index for the default channel, and host_name-relay-bin-channel.index for non-default replication channels.

The default relay log file and relay log index file names and locations can be overridden with, respectively, the --relay-log and --relay-log-index server options (see Section 17.1.6, "Replication and Binary Logging Options and Variables").

If a slave uses the default host-based relay log file names, changing a slave’s host name after replication has been set up can cause replication to fail with the errors Failed to open the relay log and Could not find target log during relay log initialization. This is a known issue (see Bug #2122). If you anticipate that a slave’s host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the --relay-log and --relay-log-index options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with FLUSH LOGS or mysqladmin flush-logs.
- When the size of the current relay log file becomes too large, which is determined as follows:
  - If the value of max_relay_log_size is greater than 0, that is the maximum relay log file size.
  - If the value of max_relay_log_size is 0, max_binlog_size determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, FLUSH LOGS rotates relay logs, which influences when the SQL thread deletes them.

### 17.2.4.2 Slave Status Logs

A replication slave server creates two slave status logs in the form of InnoDB tables in the mysql database: the master info log slave_master_info, and the relay log info log slave_relay_log_info.
The two slave status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.4.2, “SQL Statements for Controlling Slave Servers”. The slave status logs survive a slave server’s shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log table should be protected because it contains the password for connecting to the master. See Section 6.1.2.3, “Passwords and Logging”.

Before MySQL 8.0, to create the slave status logs as tables, it was necessary to specify the options `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE` at server startup. Otherwise, the logs were created as files in the data directory named `master.info` and `relay-log.info`, or with alternative names and locations specified by the `--master-info-file` and `--relay-log-info-file` options. From MySQL 8.0, creating the slave status logs as tables is the default, and creating the slave status logs as files is deprecated. For more information, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine InnoDB. Updates to the relay log info log table are committed together with the transactions, meaning that the slave’s progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the slave to guarantee resilience. For more details, see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”.

One additional slave status log is created primarily for internal use, and holds status information about worker threads on a multithreaded replication slave. This slave worker log includes the names and positions for the relay log file and master binary log file for each worker thread. If the relay log info log for the slave is created as a table, which is the default, the slave worker log is written to the `mysql.slave_worker_info` table. If the relay log info log is written to a file, the slave worker log is written to the `worker-relay-log.info` file. For external use, status information for worker threads is presented in the Performance Schema table `replication_applier_status_by_worker`.

The slave I/O thread updates the master info log. The following table shows the correspondence between the columns in the `mysql.slave_master_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the deprecated `master.info` file.

<table>
<thead>

Relay_log_name                   Relay_Log_File 2 The name of the current relay log file
### How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use to evaluate replication filtering rules, please refer to the following table:

<table>
<thead>
<tr>
<th>slave_relay_log_info Table Column</th>
<th>SHOW SLAVE STATUS Column</th>
<th>Line in relay-log.info File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relay_log_pos</td>
<td>Relay_Log_Pos</td>
<td>3</td>
<td>The current position within the relay log file; events up to this position have been executed on the slave database.</td>
</tr>
<tr>
<td>Master_log_name</td>

<td>The name of the replication channel.</td>
</tr>
</tbody>
</table>

When you back up the replication slave's data, ensure that you back up the `mysql_slave_master_info` and `mysql_slave_relay_log_info` tables containing the slave status logs, because they are needed to resume replication after you restore the data from the slave. If you lose the relay log files, but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.
How Servers Evaluate Replication Filtering Rules

in evaluating these options, see Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the --replicate-* options that the slave was started with. (See Section 17.1.6, “Replication and Binary Logging Options and Variables”. The filters governed by these options can also be set dynamically using the CHANGE REPLICATION FILTER statement. The rules governing such filters are the same whether they are created on startup using --replicate-* options or while the slave server is running by CHANGE REPLICATION FILTER. Note that replication filters cannot be used on Group Replication-specific channels on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

In the simplest case, when there are no --replicate-* options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (--replicate-do-db, --replicate-ignore-db) are checked first; see Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 17.2.5.2, “Evaluation of Table-Level Replication Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, CREATE DATABASE, DROP DATABASE, and ALTER DATABASE), database-level options always take precedence over any --replicate-wild-do-table options. In other words, for such statements, --replicate-wild-do-table options are checked if and only if there are no database-level options that apply.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any --replicate-rewrite-db options were specified, they are applied before the --replicate-* filtering rules are tested.

Note

All replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the lower_case_table_names system variable.

17.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any --replicate-do-db or --replicate-ignore-db options that apply. When using --binlog-do-db or --binlog-ignore-db, the process is similar, but the options are checked on the master.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a USE statement) is the database that is checked.

Note

Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when binlog_format=ROW. All DDL statements are therefore always filtered according to the rules for statement-based
replication. This means that you must select the default database explicitly with a `USE` statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:

1. Which logging format is used?
   - `STATEMENT`. Test the default database.
   - `ROW`. Test the database affected by the changes.

2. Are there any `--replicate-do-db` options?
   - Yes. Does the database match any of them?
     - Yes. Continue to Step 4.
     - No. Ignore the update and exit.
   - No. Continue to step 3.

3. Are there any `--replicate-ignore-db` options?
   - Yes. Does the database match any of them?
     - Yes. Ignore the update and exit.
     - No. Continue to step 4.
   - No. Continue to step 4.

4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 17.2.5.2, “Evaluation of Table-Level Replication Options”.

   **Important**
   A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
   - Yes. Continue to step 2.
   - No. Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?
   - Yes. Continue to step 3.
   - No. Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?
   - Yes. Do any of them match the database?
     - Yes. Log the statement and exit.
17.2.5.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

• No matching database options were found.

• One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as UPDATE mytable SET mycol = 1 may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any --replicate-do-table or --replicate-wild-do-table options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any --replicate-ignore-table or --replicate-wild-ignore-table options, all events are executed except those that match any of these options.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

Important

For statement-based logging, an exception is made in the rules just given for the CREATE DATABASE, ALTER DATABASE, and DROP DATABASE statements. In those cases, the database being created, altered, or dropped replaces the default database when determining whether to log or ignore updates.

--binlog-do-db can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only --binlog-do-db=sales does not write to the binary log statements for which the default database differs from sales. When using row-based logging with the same option, the server logs only those updates that change data in sales.
1. Are there any table replication options?
   • Yes. Continue to step 2.
   • No. Execute the update and exit.

2. Which logging format is used?
   • STATEMENT. Carry out the remaining steps for each statement that performs an update.
   • ROW. Carry out the remaining steps for each update of a table row.

3. Are there any --replicate-do-table options?
   • Yes. Does the table match any of them?
     • Yes. Execute the update and exit.
     • No. Continue to step 4.
   • No. Continue to step 4.

4. Are there any --replicate-ignore-table options?
   • Yes. Does the table match any of them?
     • Yes. Ignore the update and exit.
     • No. Continue to step 5.
   • No. Continue to step 5.

5. Are there any --replicate-wild-do-table options?
   • Yes. Does the table match any of them?
     • Yes. Execute the update and exit.
     • No. Continue to step 6.
   • No. Continue to step 6.

6. Are there any --replicate-wild-ignore-table options?
   • Yes. Does the table match any of them?
     • Yes. Ignore the update and exit.
     • No. Continue to step 7.
   • No. Continue to step 7.

7. Is there another table to be tested?
   • Yes. Go back to step 3.
   • No. Continue to step 8.

8. Are there any --replicate-do-table or --replicate-wild-do-table options?
How Servers Evaluate Replication Filtering Rules

• **Yes.** Ignore the update and exit.
• **No.** Execute the update and exit.

**Note**
Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The slave must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

### 17.2.5.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

<table>
<thead>
<tr>
<th>Condition (Types of Options)</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>No <code>--replicate-*</code> options at all:</td>
<td>The slave executes all events that it receives from the master.</td>
</tr>
<tr>
<td><code>--replicate-*-db</code> options, but no table options:</td>
<td>The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.</td>
</tr>
<tr>
<td><code>--replicate-*-table</code> options, but no database options:</td>
<td>All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.</td>
</tr>
<tr>
<td>A combination of database and table options:</td>
<td>The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.</td>
</tr>
</tbody>
</table>

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```
How Servers Evaluate Replication Filtering Rules

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled; the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

### 17.2.5.4 Replication Channel Based Filters

This section explains how to work with replication filters when multiple replication channels exist, for example in a multi-source replication topology. Before MySQL 8.0, replication filters were global - filters were applied to all replication channels. From MySQL 8.0, replication filters can be global or channel specific, enabling you to configure multi-source replication slaves with replication filters on specific replication channels. Channel specific replication filters are particularly useful in a multi-source replication topology when the same database or table is present on multiple masters, and the slave is only required to replicate it from one master.

For more background information, see Section 17.1.4, "MySQL Multi-Source Replication" and Section 17.2.3, "Replication Channels".

---

**Important**

On a MySQL server instance that is configured for Group Replication, channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels. Filtering on these channels would make the group unable to reach agreement on a consistent state.

---

**Overview of Replication Filters and Channels**

When multiple replication channels exist, for example in a multi-source replication topology, replication filters are applied as follows:

- Any global replication filter specified is added to the global replication filters of the filter type (`do_db`, `do_ignore_table`, and so on).

- Any channel specific replication filter adds the filter to the specified channel's replication filters for the specified filter type.

- Each slave replication channel copies global replication filters to its channel specific replication filters if no channel specific replication filter of this type is configured.

- Each channel uses its channel specific replication filters to filter the replication stream.

The syntax to create channel specific replication filters extends the existing SQL statements and command options. When a replication channel is not specified, the global replication filter is configured to ensure backwards compatibility. The `CHANGE REPLICATION FILTER` statement...
How Servers Evaluate Replication Filtering Rules

supports the `FOR CHANNEL` clause to configure channel specific filters online. The `--replicate-*` command options to configure filters can specify a replication channel using the form `--replicate-filter_type=channel_name:filter_details`. For example, suppose channels `channel_1` and `channel_2` exist before the server starts, starting the slave with the command line options `--replicate-do-db=db1 --replicate-do-db=channel_1:db2 --replicate-do-db=db3 --replicate-ignore-db=db4 --replicate-ignore-db=channel_2:db5` would result in:

- **Global replication filters**: `do_db=db1,db3, ignore_db=db4`
- **Channel specific filters on channel_1**: `do_db=db2 ignore_db=db4`
- **Channel specific filters on channel_2**: `do_db=db1,db3 ignore_db=db5`

To monitor the replication filters in such a setup use the `replication_applier_global_filters` and `replication_applier_filters` tables.

Configuring Channel Specific Replication Filters at Startup

The replication filter related command options can take an optional `channel` followed by a colon, followed by the filter specification. The first colon is interpreted as a separator, subsequent colons are interpreted as literal colons. The following command options support channel specific replication filters using this format:

- `--replicate-do-db=channel:database_id`
- `--replicate-ignore-db=channel:database_id`
- `--replicate-do-table=channel:table_id`
- `--replicate-ignore-table=channel:table_id`
- `--replicate-rewrite-db=channel:db1-db2`
- `--replicate-wild-do-table=channel:table regexid`
- `--replicate-wild-ignore-table=channel:table regexid`

If you use a colon but do not specify a `channel` for the filter option, for example `--replicate-do-db=:database_id`, the option configures the replication filter for the default replication channel. The default replication channel is the replication channel which always exists once replication has been started, and differs from multi-source replication channels which you create manually. When neither the colon nor a `channel` is specified the option configures the global replication filters, for example `--replicate-do-db=database_id` configures the global `--replicate-do-db` filter.

If you configure multiple `rewrite-db=from_name->to_name` options with the same `from_name` database, all filters are added together (put into the `rewrite_do` list) and the first one takes effect.

Changing Channel Specific Replication Filters Online

In addition to the `--replicate-*` options, replication filters can be configured using the `CHANGE REPLICATION FILTER` statement. This removes the need to restart the server, but the slave applier thread must be stopped while making the change. To make this statement apply the filter to a specific channel, use the `FOR CHANNEL channel` clause. For example:

```
CHANGE REPLICATION FILTER REPlicate_Do_DB=(db1) FOR CHANNEL channel_1;
```

When a `FOR CHANNEL` clause is provided, the statement acts on the specified channel's replication filters. If multiple types of filters (`do_db, do_ignore_table, wild_do_table`, and so on) are specified, only
the specified filter types are replaced by the statement. In a replication topology with multiple channels, for example on a multi-source replication slave, when no `FOR CHANNEL` clause is provided, the statement acts on the global replication filters and all channels’ replication filters, using a similar logic as the `FOR CHANNEL` case. For more information see Section 13.4.2.2, “CHANGE REPLICATION FILTER Syntax”.

Removing Channel Specific Replication Filters

When channel specific replication filters have been configured, you can remove the filter by issuing an empty filter type statement. For example to remove all `REPLICATE_REWRITE_DB` filters from a replication channel named `channel_1` issue:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=() FOR CHANNEL channel_1;
```

Any `REPLICATE_REWRITE_DB` filters previously configured, using either command options or `CHANGE REPLICATION FILTER`, are removed.

The `RESET SLAVE ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the slave are copied to them, and no channel specific replication filters are applied.

17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 17.3.1, “Using Replication for Backups”.

For advice and tips on using different storage engines on the master and slaves, see Section 17.3.4, “Using Replication with Different Master and Slave Storage Engines”.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 17.3.5, “Using Replication for Scale-Out”.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Section 17.3.6, “Replicating Different Databases to Different Slaves”.

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see Section 17.3.7, “Improving Replication Performance”.

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 17.3.8, “Switching Masters During Failover”.

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 17.3.9, “Setting Up Replication to Use Encrypted Connections”.

17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.
How you back up a database depends on its size and whether you are backing up only the data, or the
data and the replication slave state so that you can rebuild the slave in the event of failure. There are
therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of
your database is not too large, the `mysqldump` tool may be suitable. See Section 17.3.1.1, “Backing Up
a Slave Using mysqldump”.

- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw
data files instead. Using the raw data files option also means that you can back up the binary and relay
logs that will enable you to recreate the slave in the event of a slave failure. For more information, see
Section 17.3.1.2, “Backing Up Raw Data from a Slave”.

Another backup strategy, which can be used for either master or slave servers, is to put the server in a
read-only state. The backup is performed against the read-only server, which then is changed back to
its usual read/write operational status. See Section 17.3.1.3, “Backing Up a Master or Slave by Making It
Read Only”.

### 17.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database
in a format that enables the information to be imported into another instance of MySQL Server (see
Section 4.5.4, “mysqldump — A Database Backup Program”). Because the format of the information is
SQL statements, the file can easily be distributed and applied to running servers in the event that you need
access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may
be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to
ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using
   `mysqladmin`:

   ```shell
   mysqladmin stop-slave
   ```

   Alternatively, you can stop only the slave SQL thread to pause event execution:

   ```shell
   mysql -e 'STOP SLAVE SQL_THREAD;'
   ```

   This enables the slave to continue to receive data change events from the master’s binary log and store
   them in the relay logs using the I/O thread, but prevents the slave from executing these events and
   changing its data. Within busy replication environments, permitting the I/O thread to run during backup
   may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to
   be dumped. For example, to dump all databases:

   ```shell
   mysqldump --all-databases > fulldb.dump
   ```

3. Once the dump has completed, start slave operations again:

   ```shell
   mysqladmin start-slave
   ```

   In the preceding example, you may want to add login credentials (user name, password) to the commands,
   and bundle the process up into a script that you can run automatically each day.

   If you use this approach, make sure you monitor the slave replication process to ensure that the time
taken to run the backup does not affect the slave's ability to keep up with events from the master. See
Using Replication for Backups

Section 17.1.7.1, “Checking Replication Status”. If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 17.3.6, “Replicating Different Databases to Different Slaves”.

17.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as InnoDB. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

   ```shell
   mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including cp, tar or WinZip. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```shell
   tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:

   ```shell
   mysql_safe &
   ```

   Under Windows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld"
   ```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), in addition to the data, you need to have the master info repository and relay log info repository, and the relay log files. These items are needed to resume replication after you restore the slave’s data. If tables have been used for the master info and relay log info repositories (see Section 17.2.4, “Replication Relay and Status Logs”), which is the default in MySQL 8.0, these tables are backed up along with the data directory. If files have been used for the repositories, you must back these up separately. The relay log files must also be backed up separately if they have been placed in a different location to the data directory.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

17.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:
1. Make the server read-only, so that it processes only retrievals and blocks updates.

2. Perform the backup.

3. Change the server back to its normal read/write state.

**Note**

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, “`mysqldump — A Database Backup Program`”). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

**Scenario 1: Backup with a Read-Only Master**

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2.

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.
Handling an Unexpected Halt of a Replication Slave

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

17.3.2 Handling an Unexpected Halt of a Replication Slave

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the slave to recover its state before halting. This section describes the impact of an unexpected halt of a slave during replication and how to configure a slave for the best chance of recovery to continue replication.

After an unexpected halt of a slave, upon restart the slave's SQL thread must recover which transactions have been executed already. The information required for recovery is stored in the slave's relay log info log. From MySQL 8.0, this log is created by default as an InnoDB table named `mysql.slave_relay_log_info` (with the system variable `relay_log_info_repository` set to the default of `TABLE`). By using this transactional storage engine the information is always recoverable upon restart.

Updates to the relay log info log table are committed together with the transactions, meaning that the slave's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. Previously, this information was stored by default in a file in the data directory that was updated after the transaction had been applied. This held the risk of losing synchrony with the master depending at which stage of processing a transaction the slave halted at, or even corruption of the file itself. The setting `relay_log_info_repository = FILE` is now deprecated, and will be removed in a future release. For further information on the slave logs, see Section 17.2.4, “Replication Relay and Status Logs”.

3197
Handling an Unexpected Halt of a Replication Slave

When the relay log info log is stored in the `mysql.slave_relay_log_info` table, DML transactions and also atomic DDL make the following three updates together, atomically:

- Apply the transaction on the database.
- Update the replication positions in the `mysql.slave_relay_log_info` table.
- Update the GTID in the `mysql.gtid_executed` table (when GTIDs are enabled and the binary log is disabled on the server).

In all other cases, including DDL statements that are not fully atomic, and exempted storage engines that do not support atomic DDL, the `mysql.slave_relay_log_info` table might be missing updates associated with replicated data if the server halts unexpectedly. Restoring updates in this case is a manual process. For details on atomic DDL support in MySQL 8.0, and the resulting behavior for the replication of certain statements, see Section 13.1.1, “Atomic Data Definition Statement Support”.

Exactly how a replication slave recovers from an unexpected halt is influenced by the chosen method of replication, whether the slave is single-threaded or multithreaded, the setting of variables such as `relay_log_recovery`, and whether features such as `MASTER_AUTO_POSITION` are being used.

The following table shows the impact of these different factors on how a single-threaded slave recovers from an unexpected halt.

**Table 17.3 Factors Influencing Single-threaded Replication Slave Recovery**

<table>
<thead>
<tr>
<th>GTID</th>
<th>MASTER_AUTO_POSITION</th>
<th>relay_log_recovery</th>
<th>relay_log_info_repository</th>
<th>Crash type</th>
<th>Recovery guaranteed</th>
<th>Relay log impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Any</td>
<td>1</td>
<td>TABLE</td>
<td>Yes</td>
<td>Lost</td>
<td>Lost</td>
</tr>
<tr>
<td>OFF</td>
<td>Any</td>
<td>1</td>
<td>Any</td>
<td>No</td>
<td>Lost</td>
<td>Lost</td>
</tr>
<tr>
<td>OFF</td>
<td>Any</td>
<td>0</td>
<td>TABLE</td>
<td>Yes</td>
<td>Remains</td>
<td>Remains</td>
</tr>
<tr>
<td>OFF</td>
<td>Any</td>
<td>0</td>
<td>Any</td>
<td>No</td>
<td>Remains</td>
<td>Remains</td>
</tr>
<tr>
<td>ON</td>
<td>ON</td>
<td>Any</td>
<td>Any</td>
<td>Yes</td>
<td>Lost</td>
<td>Remains</td>
</tr>
<tr>
<td>ON</td>
<td>OFF</td>
<td>0</td>
<td>TABLE</td>
<td>Yes</td>
<td>Remains</td>
<td>Remains</td>
</tr>
<tr>
<td>ON</td>
<td>OFF</td>
<td>0</td>
<td>Any</td>
<td>No</td>
<td>Remains</td>
<td>Remains</td>
</tr>
</tbody>
</table>

As the table shows, when using a single-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery. Note that to guarantee recovery, `sync_binlog=1` (which is the default) must also be set on the slave, so that the slave’s binary log is synchronized to disk at each write. Otherwise, committed transactions might not be present in the slave’s binary log.

- When using file position based replication, set `relay_log_recovery=1` and `relay_log_info_repository=TABLE`.

  **Note**
  During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multithreaded slave recovers from an unexpected halt.
Table 17.4 Factors Influencing Multithreaded Replication Slave Recovery

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Guaranteed Recovery</th>
<th>Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTID and MASTER_AUTO_POSITION, relay_log_recovery=1</td>
<td>Yes</td>
<td>Lost</td>
</tr>
<tr>
<td>sync_relay_log=1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>relay_log_info_repository=TABLE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As the table shows, when using a multithreaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and MASTER_AUTO_POSITION, set relay_log_recovery=1. With this configuration the setting of relay_log_info_repository and other variables does not impact on recovery.

- When using file position based replication, set relay_log_recovery=1, sync_relay_log=1, and relay_log_info_repository=TABLE.

Note

During recovery the relay log is lost.

It is important to note the impact of sync_relay_log=1, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unread transaction being lost, it also has the potential to greatly increase the load on storage. Without sync_relay_log=1, the effect of an unexpected halt depends on how the relay log is handled by the operating system. Also note that when relay_log_recovery=0, the next time the slave is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multithreaded replication slave using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See Section 17.4.1.33, “Replication and Transaction Inconsistencies”. If the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically.

When you are using multi-source replication and relay_log_recovery=1, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multithreaded slave are filled.

17.3.3 Monitoring Row-based Replication

The current progress of the replication applier (SQL) thread when using row-based replication is monitored through Performance Schema instrument stages, enabling you to track the processing of operations and check the amount of work completed and work estimated. When these Performance Schema instrument
Using Replication with Different Master and Slave Storage Engines

stages are enabled the `events_stages_current` table shows stages for applier threads and their progress. For background information, see Section 26.12.5, “Performance Schema Stage Event Tables”.

To track progress of all three row-based replication event types (write, update, delete):

- Enable the three Performance Schema stages by issuing:

  ```
  mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
  -> WHERE NAME LIKE 'stage/sql/Applying batch of row changes%';
  ```

- Wait for some events to be processed by the replication applier thread and then check progress by looking into the `events_stages_current` table. For example to get progress for update events issue:

  ```
  mysql> SELECT WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
  -> WHERE EVENT_NAME LIKE 'stage/sql/Applying batch of row changes (update)'
  ```

- If `binlog_rows_query_log_events` is enabled, information about queries is stored in the binary log and is exposed in the `processlist_info` field. To see the original query that triggered this event:

  ```
  mysql> SELECT db, processlist_state, processlist_info FROM performance_schema.threads
  -> WHERE processlist_state LIKE 'stage/sql/Applying batch of row changes%' AND thread_id = N;
  ```

### 17.3.4 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` system variable is not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 17.3.5, “Using Replication for Scale-Out”), you want to use InnoDB tables on the master to take advantage of the transactional functionality, but use MyISAM on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the Archive storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-federated` option on your slave to disable the FEDERATED engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually MyISAM. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.
If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

   ```
   mysql> STOP SLAVE;
   ```

   This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the slave replication process again:

   ```
   mysql> START SLAVE;
   ```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

   ```
   mysql> ALTER TABLE csvtable Engine='MyISAM';
   ```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

   ```
   mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
   ```

Use this format:

   ```
   mysql> SET default_storage_engine=MyISAM;
   mysql> CREATE TABLE tablea (columna int);
   ```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

### 17.3.5 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 17.1, “Using Replication to Improve Performance During Scale-Out”. 
If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by writing a conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 17.3.6 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.
You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

**Important**
You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

**Note**
This does not work with InnoDB databases unless you use `innodb_file_per_table`. 
17.3.7 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 17.3, “Using an Additional Replication Host to Improve Performance”.

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging is enabled on both masters, which is the default.

- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 has the `--log-slave-updates` option enabled (which is the default). With this option, replication instructions from Master 1 are also written to Master 2’s binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.

- If heavy disk I/O activity for reads of the binary log file and relay log files is an issue, consider increasing the value of the `rpl_read_size` system variable. This system variable controls the minimum amount of data read from the log files, and increasing it might reduce file reads and I/O stalls when the file data is not currently cached by the operating system. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on masters and coordinator threads on slaves. Setting a large value might therefore have an impact on memory consumption for servers.
Switching Masters During Failover

- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 17.3.6, “Replicating Different Databases to Different Slaves”.

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use MyISAM or another nontransactional engine on the slaves. See Section 17.3.4, “Using Replication with Different Master and Slave Storage Engines”.

- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you may switch off `--log-slave-updates` on the slaves. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

### 17.3.8 Switching Masters During Failover

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with binary logging enabled (the `--log-bin` option), which is the default. If you are not using GTIDs for replication, then the slaves should also be run with `--skip-log-slave-updates` (logging slave updates is the default). In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in Figure 17.4, “Redundancy Using Replication, Initial Structure”.

**Figure 17.4 Redundancy Using Replication, Initial Structure**

In this diagram, the **MySQL Master** holds the master database, the **MySQL Slave** hosts are replication slaves, and the **Web Client** machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 17.3.5, “Using Replication for Scale-Out”.

Each MySQL Slave (Slave 1, Slave 2, and Slave 3) is a slave running with binary logging enabled, and with `--skip-log-slave-updates`. Because updates received by a slave from the master are not
Switching Masters During Failover

logged in the binary log when `--skip-log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason MySQL Master becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick Slave 1, all Web Clients should be redirected to Slave 1, which writes the updates to its binary log. Slave 2 and Slave 3 should then replicate from Slave 1.

The reason for running the slave with `--skip-log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If Slave 1 has `--log-slave-updates` enabled, which is the default, it writes any updates that it receives from Master in its own binary log. This means that, when Slave 2 changes from Master to Slave 1 as its master, it may receive updates from Slave 1 that it has already received from Master.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave Slave 1 being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves Slave 2 and Slave 3, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where 'Slave1' represents the real host name of Slave 1). To use `CHANGE MASTER TO`, add all information about how to connect to Slave 1 from Slave 2 or Slave 3 (user, password, port). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the Slave 1 binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on Slave 2 and Slave 3. Once the new replication setup is in place, you need to tell each Web Client to direct its statements to Slave 1. From that point on, all update statements sent by Web Client to Slave 1 are written to the binary log of Slave 1, which then contains every update statement sent to Slave 1 since Master died.

The resulting server structure is shown in Figure 17.5, “Redundancy Using Replication, After Master Failure”.

**Figure 17.5 Redundancy Using Replication, After Master Failure**
When Master becomes available again, you should make it a slave of Slave 1. To do this, issue on Master the same CHANGE MASTER TO statement as that issued on Slave 2 and Slave 3 previously. Master then becomes a slave of Slave 1 and picks up the Web Client writes that it missed while it was offline.

To make Master a master again, use the preceding procedure as if Slave 1 was unavailable and Master was to be the new master. During this procedure, do not forget to run RESET MASTER on Master before making Slave 1, Slave 2, and Slave 3 slaves of Master. If you fail to do this, the slaves may pick up stale writes from the Web Client applications dating from before the point at which Master became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With bind you can use nsupdate to update the DNS dynamically.

### 17.3.9 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see Section 6.4.1, “Configuring MySQL to Use Encrypted Connections”.

To enable encrypted connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master’s configuration within the [mysqld] section of the master's my.cnf file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- **--ssl-ca**: The path name of the Certificate Authority (CA) certificate file. (**--ssl-capath** is similar but specifies the path name of a directory of CA certificate files.)
- **--ssl-cert**: The path name of the server public key certificate file. This can be sent to the client and authenticated against the CA certificate that it has.
- **--ssl-key**: The path name of the server private key file.

To enable encrypted connections on the slave, use the `CHANGE MASTER TO` statement. You can either name the slave certificate and SSL private key files required for the encrypted connection in the [client] section of the slave's my.cnf file, or you can explicitly specify that information using the `CHANGE MASTER`
TO statement. For more information on the CHANGE MASTER TO statement, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

To name the slave certificate and key files using an option file, add the following lines to the [client] section of the slave's my.cnf file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the --skip-slave-start option to prevent the slave from connecting to the master. Use CHANGE MASTER TO to specify the master configuration, and add the MASTER_SSL option to connect using encryption:

```
mysql> CHANGE MASTER TO
  -> MASTER_HOST='master_hostname',
  -> MASTER_USER='repl',
  -> MASTER_PASSWORD='password',
  -> MASTER_SSL=1;
```

Setting MASTER_SSL=1 for a replication connection and then setting no further MASTER_SSL_xxx options corresponds to setting --ssl-mode=REQUIRED for the client, as described in Section 6.4.2, "Command Options for Encrypted Connections". With MASTER_SSL=1, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the --ssl-mode=PREFERRED setting for replication. If MASTER_SSL=0 is set, this corresponds to --ssl-mode=DISABLED.

To name the slave certificate and SSL private key files using the CHANGE MASTER TO statement, if you did not do this in the slave's my.cnf file, add the appropriate MASTER_SSL_xxx options:

```
  -> MASTER_SSL_CA = 'ca_file_name',
  -> MASTER_SSL_CAPATH = 'ca_directory_name',
  -> MASTER_SSL_CERT = 'cert_file_name',
  -> MASTER_SSL_KEY = 'key_file_name',
```

These options correspond to the --ssl-xxx options with the same names, as described in Section 6.4.2, "Command Options for Encrypted Connections". For these options to take effect, MASTER_SSL=1 must also be set. For a replication connection, specifying a value for either of MASTER_SSL_CA or MASTER_SSL_CAPATH, or specifying these options in the slave's my.cnf file, corresponds to setting --ssl-mode=VERIFY_CA. The connection attempt only succeeds if a valid matching Certificate Authority (CA) certificate is found using the specified information.

To activate host name identity verification, add the MASTER_SSL_VERIFY_SERVER_CERT option:

```
  -> MASTER_SSL_VERIFY_SERVER_CERT=1,
```

This option corresponds to the --ssl-verify-server-cert option, which was deprecated from MySQL 5.7 and removed in MySQL 8.0. For a replication connection, specifying MASTER_SSL_VERIFY_SERVER_CERT=1 corresponds to setting --ssl-mode=VERIFY_IDENTITY, as described in Section 6.4.2, "Command Options for Encrypted Connections". For this option to take effect, MASTER_SSL=1 must also be set. Host name identity verification does not work with self-signed certificates.

To activate certificate revocation list (CRL) checks, add the MASTER_SSL_CRL or MASTER_SSL_CRLPATH option:
Encrypting Binary Log Files and Relay Log Files

These options correspond to the --ssl-xxx options with the same names, as described in Section 6.4.2, “Command Options for Encrypted Connections”. If they are not specified, no CRL checking takes place.

• To specify lists of permitted ciphers and encryption protocols for the replication connection, add the MASTER_SSL_CIPHER and MASTER_TLS_VERSION options:

---
>
---

The MASTER_SSL_CIPHER option specifies the list of permitted ciphers for the replication connection, with one or more cipher names separated by colons. The MASTER_TLS_VERSION option specifies the encryption protocols permitted for the replication connection. The format is like that for the tls_version system variable, with one or more protocol names separated by commas. The protocols and ciphers that you can use in these lists depend on the SSL library used to compile MySQL. For information about the formats and permitted values, see Section 6.4.6, “Encrypted Connection Protocols and Ciphers”.

• After the master information has been updated, start the slave replication process:

mysql> START SLAVE;

You can use the SHOW SLAVE STATUS statement to confirm that an encrypted connection was established successfully.

• Requiring encrypted connections on the slave does not ensure that the master requires encrypted connections from slaves. If you want to ensure that the master only accepts replication slaves that connect using encrypted connections, create a replication user account on the master using the REQUIRE_SSL option, then grant that user the REPLICATION_SLAVE privilege. For example:

mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password'
-> REQUIRE_SSL;
mysql> GRANT REPLICATION_SLAVE ON *.*
-> TO 'repl'@'%.example.com';

If you have an existing replication user account on the master, you can add REQUIRE_SSL to it with this statement:

mysql> ALTER USER 'repl'@'%.example.com' REQUIRE_SSL;

17.3.10 Encrypting Binary Log Files and Relay Log Files

From MySQL 8.0.14, binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. The encryption algorithm used for the files, the AES (Advanced Encryption Standard) cipher algorithm, is built in to MySQL Server and cannot be configured. Binary log encryption is supported for OpenSSL and wolfSSL builds of MySQL Server.

You enable this encryption on a MySQL server by setting the binlog_encryption system variable to ON. OFF is the default. The system variable sets encryption on for binary log files and relay log files. Binary
Encrypting Binary Log Files and Relay Log Files

logging does not need to be enabled on the server to enable encryption, so you can encrypt the relay log files on a slave that has no binary log. To use encryption, a keyring plugin must be installed and configured to supply MySQL Server's keyring service. For instructions to do this, see Section 6.5.4, "The MySQL Keyring". Any supported keyring plugin can be used to store binary log encryption keys.

When you first start the server with encryption enabled, a new binary log encryption key is generated before the binary log and relay logs are initialized. This key is used to encrypt a file password for each binary log file (if the server has binary logging enabled) and relay log file (if the server has replication channels), and further keys generated from the file passwords are used to encrypt the data in the files. Relay log files are encrypted for all channels, including Group Replication applier channels and new channels that are created after encryption is activated. The binary log index file and relay log index file are never encrypted.

If you activate encryption while the server is running, a new binary log encryption key is generated at that time. The exception is if encryption was active previously on the server and was then disabled, in which case the binary log encryption key that was in use before is used again. The binary log file and relay log files are rotated immediately, and file passwords for the new files and all subsequent binary log files and relay log files are encrypted using this binary log encryption key. Existing binary log files and relay log files still present on the server are not encrypted, but you can purge them if they are no longer needed.

If you deactivate encryption by changing the `binlog_encryption` system variable to `OFF`, the binary log file and relay log files are rotated immediately and all subsequent logging is unencrypted. Previously encrypted files are not automatically decrypted, but the server is still able to read them. `SUPER` privileges or the `BINLOG_ENCRYPTION_ADMIN` privilege are required to activate or deactivate encryption while the server is running. Group Replication applier channels are not included in the relay log rotation request, so unencrypted logging for these channels does not start until their logs are rotated in normal use.

Encrypted and unencrypted binary log files can be distinguished using the magic number at the start of the file header for encrypted log files (0xFD62696E), which differs from that used for unencrypted log files (0xFE62696E). The `SHOW BINARY LOGS` statement shows whether each binary log file is encrypted or unencrypted.

Note that when encryption is active for a MySQL server instance, only the data at rest that is written to the binary log files and relay log files is encrypted. The data in motion in the replication event stream, which is sent to MySQL clients including `mysqlbinlog`, is always in unencrypted format, so it must be protected in transit by the use of connection encryption (see Section 6.4, “Using Encrypted Connections”). The data in use that is held in the binary log transaction and statement caches during a transaction, and any data that exceeds the space available in those caches and is therefore stored in a temporary file on disk, is also in unencrypted format. The temporary files and caches are deleted when the thread that handles the transaction ends. The server status variables `Binlog_cache_disk_use` and `Binlog_stmt_cache_disk_use` show whether any data has been stored in temporary files, and you can increase the size of the binary log cache or binary log statement cache if you want to minimize the possibility of having unencrypted temporary files for the duration of a transaction.

When binary log files have been encrypted, `mysqlbinlog` cannot read them directly, but can read them from the server using the `--read-from-remote-server` option. From MySQL 8.0.14, `mysqlbinlog` returns a suitable error if you attempt to read an encrypted binary log file directly, but older versions of `mysqlbinlog` do not recognise the file as a binary log file at all. If you back up encrypted binary log files using `mysqlbinlog`, note that the copies of the files that are generated using `mysqlbinlog` are stored in an unencrypted format.

**Binary log encryption keys**

The binary log encryption keys used to encrypt the file passwords for the log files are 256-bit keys that are generated specifically for each MySQL server instance using MySQL Server's keyring service (see
Section 6.5.4, “The MySQL Keyring”). The keyring service handles the creation, retrieval, and deletion of the binary log encryption keys. A server instance only creates and removes keys generated for itself, but it can read keys generated for other instances if they are stored in the keyring, as in the case of a server instance that has been cloned by file copying.

Important

The binary log encryption keys for a MySQL server instance must be included in your backup and recovery procedures, because if the keys required to decrypt the file passwords for current and retained binary log files or relay log files are lost, it might not be possible to start the server.

The format of binary log encryption keys in the keyring is as follows:

MySQLReplicationKey_{UUID}_{SEQ_NO}

For example:

MySQLReplicationKey_00508583-b5ce-11e8-a6a5-0010e0734796_1

{UUID} is the true UUID generated by the MySQL server (the value of the server_uuid system variable). {SEQ_NO} is the sequence number for the binary log encryption key, which is incremented by 1 for each new key that is generated on the server.

The binary log encryption key that is currently in use on the server is called the binary log master key. The sequence number for the current binary log master key is stored in the keyring. The binary log master key is used to encrypt each new log file's file password, which is a randomly generated 32-byte file password specific to the log file that is used to encrypt the file data. The file password is encrypted using AES-CBC (AES Cipher Block Chaining mode) with the 256-bit binary log encryption key and a random initialization vector (IV), and is stored in the log file's file header. The file data is encrypted using AES-CTR (AES Counter mode) with a 256-bit key generated from the file password and a nonce also generated from the file password. It is technically possible to decrypt an encrypted file offline, if the binary log encryption key used to encrypt the file password is known, by using tools available in the OpenSSL cryptography toolkit.

The binlog_rotate_encryption_master_key_at_startup system variable controls whether the binary log master key is automatically rotated when the server is restarted. If this system variable is set to ON, a new binary log encryption key is generated and used as the new binary log master key whenever the server is restarted. If it is set to OFF, which is the default, the existing binary log master key is used again after the restart.

If you use file copying to clone a MySQL server instance that has encryption active so its binary log files and relay log files are encrypted, ensure that the keyring is also copied, so that the clone server can read the binary log encryption keys from the source server. When encryption is activated on the clone server (either at startup or subsequently), the clone server recognizes that the binary log encryption keys used with the copied files include the generated UUID of the source server. It automatically generates a new binary log encryption key using its own generated UUID, and uses this to encrypt the file passwords for subsequent binary log files and relay log files. The copied files continue to be read using the source server's keys.

17.3.11 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 8.0 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.
Semisynchronous Replication

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.

- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.

- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.

- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

The number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.

- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.

- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves.
Semisynchronous Replication

to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by rpl_semi_sync_master_wait_for_slave_count, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The rpl_semi_sync_master_wait_point system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- **AFTER_SYNC** (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.

- **AFTER_COMMIT**: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With **AFTER_SYNC**, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

  In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With **AFTER_COMMIT**, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

  If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

**17.3.11.1 Semisynchronous Replication Administrative Interface**

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
Semisynchronous Replication

• System variables control plugin behavior. Some examples:
  
  • rpl_semi_sync_master_enabled
    Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

  • rpl_semi_sync_master_timeout
    A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

  • rpl_semi_sync_slave_enabled
    Similar to rpl_semi_sync_master_enabled, but controls the slave plugin.

All rpl_semi_sync_xxx system variables are described at Section 5.1.8, “Server System Variables”.

• Status variables enable semisynchronous replication monitoring. Some examples:

  • Rpl_semi_sync_master_clients
    The number of semisynchronous slaves.

  • Rpl_semi_sync_master_status
    Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

  • Rpl_semi_sync_master_no_tx
    The number of commits that were not acknowledged successfully by a slave.

  • Rpl_semi_sync_master_yes_tx
    The number of commits that were acknowledged successfully by a slave.

  • Rpl_semi_sync_slave_status
    Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All Rpl_semi_sync_xxx status variables are described at Section 5.1.10, “Server Status Variables”.

The system and status variables are available only if the appropriate master or slave plugin has been installed with INSTALL PLUGIN.

17.3.11.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.

- Replication must already be working, see Section 17.1, “Configuring Replication”.

- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See Section 17.2.3, “Replication Channels”.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library '/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from https://dev.mysql.com/downloads/os-linux.html.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:
Semisynchronous Replication

```plaintext
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    -> FROM INFORMATION_SCHEMA.PLUGINS
    -> WHERE PLUGIN_NAME LIKE '%semi%';

+----------------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>rpl_semi_sync_master</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+----------------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```plaintext
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```plaintext
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```plaintext
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```plaintext
[mysqld]
  rpl_semi_sync_master_enabled=1
  rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```plaintext
[mysqld]
  rpl_semi_sync_slave_enabled=1
```
17.3.11.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```sql
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```sql
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

17.3.12 Delayed Replication

MySQL supports delayed replication such that a slave server deliberately executes transactions later than the master by at least a specified amount of time. This section describes how to configure a replication delay on a slave, and how to monitor replication delay.

In MySQL 8.0, the method of delaying replication depends on two timestamps, `immediate_commit_timestamp` and `original_commit_timestamp` (see Replication Delay Timestamps). If all servers in the replication topology are running MySQL 8.0.1 or above, delayed replication is measured using these timestamps. If either the immediate master or slave is not using these timestamps, the implementation of delayed replication from MySQL 5.7 is used (see Delayed Replication). This section describes delayed replication between servers which are all using these timestamps.

The default replication delay is 0 seconds. Use the `CHANGE MASTER TO MASTER_DELAY=N` statement to set the delay to $N$ seconds. A transaction received from the master is not executed until at least $N$ seconds later than its commit on the immediate master. The delay happens per transaction (not event as in previous MySQL versions) and the actual delay is imposed only on `gtid_log_event` or `anonymous_gtid_log_event`. The other events in the transaction always follow these events without any waiting time imposed on them.

Note

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.
Delayed Replication

The *replication_applier_configuration* Performance Schema table contains the `DESIRED_DELAY` column which shows the delay configured using the `MASTER_DELAY` option. The *replication_applier_status* Performance Schema table contains the `REMAINING_DELAY` column which shows the number of delay seconds remaining.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. With a delay you can roll back a delayed slave to the time just before the mistake.

- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.

- To inspect what the database looked like in the past, without having to reload a backup. For example, by configuring a slave with a delay of one week, if you then need to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

**Replication Delay Timestamps**

MySQL 8.0 provides a new method for measuring delay (also referred to as replication lag) in replication topologies that depends on the following timestamps associated with the GTID of each transaction (instead of each event) written to the binary log.

- **original_commit_timestamp**: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the original master.

- **immediate_commit_timestamp**: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the immediate master.

The output of `mysqlbinlog` displays these timestamps in two formats, microseconds from epoch and also `TIMESTAMP` format, which is based on the user defined timezone for better readability. For example:

```
#170404 10:48:05 server id 1 end_log_pos 233 CRC32 0x016ce647 GTID last_committed=0
\ sequence_number=1 original_commit_timestamp=1491299285661130 immediate_commit_timestamp=1491299285843771
# original_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)

# at 233
```

As a rule, the `original_commit_timestamp` is always the same on all replicas where the transaction is applied. In master-slave replication, the `original_commit_timestamp` of a transaction in the (original) master’s binary log is always the same as its `immediate_commit_timestamp`. In the slave’s relay log, the `original_commit_timestamp` and `immediate_commit_timestamp` of the transaction are the same as in the master’s binary log; whereas in its own binary log, the transaction’s `immediate_commit_timestamp` corresponds to when the slave committed the transaction.

In a Group Replication setup, when the original master is a member of a group, the `original_commit_timestamp` is generated when the transaction is ready to be committed. In other words, when it finished executing on the original master and its write set is ready to be sent to all members of the group for certification. Therefore, the same `original_commit_timestamp` is replicated to all servers (regardless of whether it is a group member or slave replicating from a member) applying the transaction and each stores in its binary log the local commit time using `immediate_commit_timestamp`. 

3218
Delayed Replication

View change events, which are exclusive to Group Replication, are a special case. Transactions containing these events are generated by each server but share the same GTID (so, they are not first executed in a master and then replicated to the group, but all members of the group execute and apply the same transaction). Since there is no original master, these transactions have their `original_commit_timestamp` set to zero.

Monitoring Replication Delay

One of the most common ways to monitor replication delay (lag) in previous MySQL versions was by relying on the `Seconds_Behind_Master` field in the output of `SHOW SLAVE STATUS`. However, this metric is not suitable when using replication topologies more complex than the traditional master-slave setup, such as Group Replication. The addition of `immediate_commit_timestamp` and `original_commit_timestamp` to MySQL 8 provides a much finer degree of information about replication delay. The recommended method to monitor replication delay in a topology that supports these timestamps is using the following Performance Schema tables.

- `replication_connection_status`: current status of the connection to the master, provides information on the last and current transaction the connection thread queued into the relay log.
- `replication_applier_status_by_coordinator`: current status of the coordinator thread that only displays information when using a multithreaded slave, provides information on the last transaction buffered by the coordinator thread to a worker’s queue, as well as the transaction it is currently buffering.
- `replication_applier_status_by_worker`: current status of the thread(s) applying transactions received from the master, provides information about the transactions applied by the applier thread, or by each worker when using a multithreaded slave.

Using these tables you can monitor information about the last transaction the corresponding thread processed and the transaction that thread is currently processing. This information comprises:

- a transaction’s GTID
- a transaction’s `original_commit_timestamp` and `immediate_commit_timestamp`, retrieved from the slave’s relay log
- the time a thread started processing a transaction
- for the last processed transaction, the time the thread finished processing it

In addition to the Performance Schema tables, the output of `SHOW SLAVE STATUS` has three fields that show:

- `SQL_Delay`: A nonnegative integer indicating the replication delay configured using `CHANGE MASTER TO MASTER_DELAY=N`, measured in seconds.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`. 
17.4 Replication Notes and Tips

17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In other words, successful statement-based replication requires that any SQL features used be supported by both the master and the slave servers. If you use a feature on the master server that is available only in the current version of MySQL, you cannot replicate to a slave that uses an earlier version of MySQL. Such incompatibilities can also occur within a release series as well as between versions.

If you are planning to use statement-based replication between MySQL 8.0 and a previous MySQL release series, it is a good idea to consult the edition of the MySQL Reference Manual corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL’s statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL’s row-based replication instead. For a detailed list of issues, see Section 24.7, “Binary Logging of Stored Programs”. For more information about row-based logging and row-based replication, see Section 5.4.4.1, “Binary Logging Formats”, and Section 17.2.1, “Replication Formats”.

For additional information specific to replication and InnoDB, see Section 15.18, “InnoDB and MySQL Replication”. For information relating to replication with NDB Cluster, see Section 22.6, “NDB Cluster Replication”.

17.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of AUTO_INCREMENT, LAST_INSERT_ID(), and TIMESTAMP values is carried out subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an AUTO_INCREMENT column is not replicated correctly using statement-based replication. These statements are marked as unsafe. (Bug #45677)

- An INSERT into a table that has a composite primary key that includes an AUTO_INCREMENT column that is not the first column of this composite key is not safe for statement-based logging or replication. These statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the InnoDB storage engine, since an InnoDB table with an AUTO_INCREMENT column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an AUTO_INCREMENT column to a table with ALTER TABLE might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an AUTO_INCREMENT number. Assuming that you want to add an AUTO_INCREMENT column to a table t1 that has columns col1 and col2, the following statements produce a new table t2 identical to t1 but with an AUTO_INCREMENT column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```
Replication Features and Issues

Important
To guarantee the same ordering on both master and slave, the ORDER BY clause must name all columns of \texttt{t1}.

The instructions just given are subject to the limitations of CREATE TABLE ... LIKE: Foreign key definitions are ignored, as are the DATA DIRECTORY and INDEX DIRECTORY table options. If a table definition includes any of those characteristics, create \texttt{t2} using a CREATE TABLE statement that is identical to the one used to create \texttt{t1}, but with the addition of the AUTO_INCREMENT column.

Regardless of the method used to create and populate the copy having the \texttt{AUTO_INCREMENT} column, the final step is to drop the original table and then rename the copy:

\begin{verbatim}
DROP t1;
ALTER TABLE t2 RENAME t1;
\end{verbatim}

See also Section B.6.6.1, “Problems with ALTER TABLE”.

17.4.1.2 Replication and BLACKHOLE Tables

The \texttt{BLACKHOLE} storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting \texttt{BLACKHOLE} tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs.

For this reason we recommend when you replicate to tables using the \texttt{BLACKHOLE} storage engine that you have the \texttt{binlog_format} server variable set to \texttt{STATEMENT}, and not to either \texttt{ROW} or \texttt{MIXED}.

17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global \texttt{character_set_server} value, you should design your CREATE TABLE statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in CREATE TABLE statements.

17.4.1.4 Replication and CHECKSUM TABLE

\texttt{CHECKSUM TABLE} returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

17.4.1.5 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

The statements CREATE SERVER, ALTER SERVER, and DROP SERVER are not written to the binary log, regardless of the binary logging format that is in use.

17.4.1.6 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various CREATE ... IF NOT EXISTS statements are replicated:

- Every CREATE DATABASE IF NOT EXISTS statement is replicated, whether or not the database already exists on the master.
Replication Features and Issues

- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Section 17.4.1.7, “Replication of CREATE TABLE ... SELECT Statements”, for more information.

- `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the master.

17.4.1.7 Replication of CREATE TABLE ... SELECT Statements

MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Section 13.3.3, “Statements That Cause an Implicit Commit”).

- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

- If the `CREATE TABLE ... SELECT` statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

- If the destination table exists and `IF NOT EXISTS` is given, MySQL 8.0 ignores the statement completely; nothing is inserted or logged.

When statement-based replication is in use, MySQL 8.0 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

17.4.1.8 Replication of CURRENT_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
Replication Features and Issues

- **ALTER_EVENT**
- **ALTER_VIEW**
- **SET_PASSWORD**

When binary logging is enabled and `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the master and the slave when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the master is replicated to the slave as metadata, and the slave applies the statement to the current user named in the metadata, rather than to the current user on the slave.

### 17.4.1.9 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

**Note**

Replication between tables which are partitioned differently from one another is not supported. See Section 17.4.1.24, “Replication and Partitioning”.

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

#### Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.
  
  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an `ALTER_TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE_TABLE` statement:

  ```sql
  CREATE TABLE t (  
  c1 INT,  
  c2 INT,  
  c3 INT  
  );
  ```

  Suppose that the `ALTER_TABLE` statement shown here is executed on the slave:

  ```sql
  ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
  ```
The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

• Each “extra” column in the version of the table having more columns must have a default value.

  A column’s default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.7, “Data Type Default Values”.

In addition, when the slave’s copy of the table has more columns than the master’s copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave’s version of the table appears before the definitions for the columns which are common to both versions of the table:
Replication Features and Issues

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

| master> | CREATE TABLE t1 (c1 INT, c2 INT); |
| slave>  | CREATE TABLE t1 (c3 INT, c1 INT, c2 INT); |

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as attribute promotion.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

**Important**

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

**Row-based replication: attribute promotion and demotion.** Row-based replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a lossy conversion. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a non-lossy conversion.

**Type conversion modes (slave_type_conversions variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave.
Replication Features and Issues

This variable takes a set of values from the following list, which describes the effects of each mode on the slave’s type-conversion behavior:

**ALL_LOSSY**

In this mode, type conversions that would mean loss of information are permitted.

This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling only this mode permits an INT column to be converted to TINYINT (a lossy conversion), but not a TINYINT column to an INT column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.

**ALL_NON_LOSSY**

This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.

Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the ALL_LOSSY mode. If only ALL_NON_LOSSY is set, but not ALL_LOSSY, then attempting a conversion that would result in the loss of data (such as INT to TINYINT, or CHAR(25) to VARCHAR(20)) causes the slave to stop with an error.

**ALL_LOSSY,ALL_NON_LOSSY**

When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.

**ALL_SIGNED**

Treat promoted integer types as signed values (the default behavior).

**ALL_UNSIGNED**

Treat promoted integer types as unsigned values.

**ALL_SIGNED,ALL_UNSIGNED**

Treat promoted integer types as signed if possible, otherwise as unsigned.

**[empty]**

When slave_type_conversions is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. You can control this behavior using ALL_SIGNED, ALL_UNSIGNED, or both. ALL_SIGNED tells the slave to treat all promoted integer types as signed; ALL_UNSIGNED instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither ALL_SIGNED nor ALL_UNSIGNED has any effect if at least one of ALL_LOSSY or ALL_NONLOSSY is not also used.

Changing the type conversion mode requires restarting the slave with the new slave_type_conversions setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT.

  This includes conversions between the signed and unsigned versions of these types.
Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.
  
  - `FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where `D' >= D` and `(M'-D') >= (M-D)` is non-lossy; for any case where `M' < M`, `D' < D`, or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.25.4, “Rounding Behavior”, for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.
  
  Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` characters of the string on the slave, where `N` is the width of the target column.

  **Important**
  
  Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

  Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` bytes of the string on the slave, where `N` is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

  When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where `M' > M`, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the `M` bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

  When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where `M' < M`, the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

### 17.4.1.10 Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA_DIRECTORY` and `INDEX_DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see Section 5.1.11, “Server SQL Modes”.
17.4.1.11 Replication of DROP ... IF EXISTS Statements

The DROP DATABASE IF EXISTS, DROP TABLE IF EXISTS, and DROP VIEW IF EXISTS statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

DROP ... IF EXISTS statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

17.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.2, “Type Conversion in Expression Evaluation”, and Section B.6.4.8, “Problems with Floating-Point Values”.

17.4.1.13 Replication and FLUSH

Some forms of the FLUSH statement are not logged because they could cause problems if replicated to a slave: FLUSH LOGS and FLUSH TABLES WITH READ LOCK. For a syntax example, see Section 13.7.7.3, “FLUSH Syntax”. The FLUSH TABLES, ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the mysql database and update those tables directly without using GRANT, you must issue a FLUSH PRIVILEGES on the slaves to put the new privileges into effect. In addition, if you use FLUSH TABLES when renaming a MyISAM table that is part of a MERGE table, you must issue FLUSH TABLES manually on the slaves. These statements are written to the binary log unless you specify NO_WRITE_TO_BINLOG or its alias LOCAL.

17.4.1.14 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The USER(), CURRENT_USER() (or CURRENT_USER), UUID(), VERSION(), and LOAD_FILE() functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Section 17.2.1, “Replication Formats”.)

USER() and CURRENT_USER() are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode. (See also Section 17.4.1.8, “Replication of CURRENT_USER()”). This is also true for VERSION() and RAND().

- For NOW(), the binary log includes the timestamp. This means that the value as returned by the call to this function on the master is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also Section 17.4.1.32, “Replication and Time Zones”.

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table mytable, perform an INSERT statement on this table, and then select from the table, as shown here:
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
<table>
<thead>
<tr>
<th>mycol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-09-01 12:00:00</td>
</tr>
</tbody>
</table>
+---------------------+
1 row in set (0.00 sec)

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave’s copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave’s copy of `mytable`, you obtain exactly the same result as on the master:

mysql> SELECT * FROM mytable;
+---------------------+
<table>
<thead>
<tr>
<th>mycol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-09-01 12:00:00</td>
</tr>
</tbody>
</table>
+---------------------+
1 row in set (0.00 sec)

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also Section 17.4.1.32, “Replication and Time Zones”.

• The following restriction applies to statement-based replication only, not to row-based replication.
  The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

  These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```sql
mysql> SELECT * FROM mytable;
+---------------------+
<table>
<thead>
<tr>
<th>mycol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-09-01 12:00:00</td>
</tr>
</tbody>
</table>
+---------------------+
1 row in set (0.00 sec)
```
To work around the problem, do this instead:

```sql
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```sql
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```sql
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```sql
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```sql
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

17.4.1.15 Replication and Fractional Seconds Support

MySQL 8.0 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See Section 11.3.5, “Fractional Seconds in Time Values”.

17.4.1.16 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:
• The effects of the feature are always replicated.

• The following statements are replicated using statement-based replication:
  
  - CREATE EVENT
  - ALTER EVENT
  - DROP EVENT
  - CREATE PROCEDURE
  - DROP PROCEDURE
  - CREATE FUNCTION
  - DROP FUNCTION
  - CREATE TRIGGER
  - DROP TRIGGER

However, the effects of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

• In the case of CREATE EVENT and ALTER EVENT:

  • The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to DROP EVENT).

  • The master on which the event was created is identified on the slave by its server ID. The ORIGINATOR column in INFORMATION_SCHEMA.EVENTS and the originator column in mysql.event store this information. See Section 25.10, "The INFORMATION_SCHEMA EVENTS Table", and Section 13.7.6.18, "SHOW EVENTS Syntax", for more information.

  • The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the INFORMATION_SCHEMA.EVENTS table in a manner similar to what is shown here:

```sql
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the SHOW EVENTS statement, like this:
SHOW EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED';

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where `event_name` is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED'
 AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED'
 AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

17.4.1.17 Replication of JSON Documents

Before MySQL 8.0, an update to a JSON column was always written to the binary log as the complete document. In MySQL 8.0, it is possible to log partial updates to JSON documents (see Partial Updates of JSON Values), which is more efficient. The logging behavior depends on the format used, as described here:

**Statement-based replication.** JSON partial updates are always logged as partial updates. This cannot be disabled when using statement-based logging.

**Row-based replication.** JSON partial updates are not logged as such by default, but instead are logged as complete documents. To enable logging of partial updates, set `binlog_row_value_options=PARTIAL_JSON`. If a replication master has this variable set, partial updates received from that master are handled and applied by a replication slave regardless of the slave’s own setting for the variable.

Servers running MySQL 8.0.2 or earlier do not recognize the log events used for JSON partial updates. For this reason, when replicating to such a server from a server running MySQL 8.0.3 or later,
Replication Features and Issues

`binlog_row_value_options` must be disabled on the master by setting this variable to '' (empty string). See the description of this variable for more information.

### 17.4.1.18 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

  When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

### 17.4.1.19 Replication and LOAD DATA

LOAD DATA is considered unsafe for statement-based logging (see Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”.

### 17.4.1.20 Replication and max_allowed_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

On a multi-threaded slave (with `slave_parallel_workers > 0`), ensure that the `slave_pending_jobs_size_max` system variable is set to a value equal to or greater than the setting for the `max_allowed_packet` system variable on the master. The default setting for `slave_pending_jobs_size_max`, 128M, is twice the default setting for `max_allowed_packet`, which is 64M. `max_allowed_packet` limits the packet size that the master will send, but the addition of an event header can produce a binary log event exceeding this size. Also, in row-based replication, a single event can be significantly larger than the `max_allowed_packet` size, because the value of `max_allowed_packet` only limits each column of the table.
The replication slave actually accepts packets up to the limit set by its `slave_max_allowed_packet` setting, which defaults to the maximum setting of 1GB, to prevent a replication failure due to a large packet. However, the value of `slave_pending_jobs_size_max` controls the memory that is made available on the slave to hold incoming packets. The specified memory is shared among all the slave worker queues.

The value of `slave_pending_jobs_size_max` is a soft limit, and if an unusually large event (consisting of one or multiple packets) exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. So although unusual events larger than `slave_pending_jobs_size_max` can be processed, the delay to clear the queues of all the slave workers and the wait to queue subsequent transactions can cause lag on the replication slave and decreased concurrency of the slave workers. `slave_pending_jobs_size_max` should therefore be set high enough to accommodate most expected event sizes.

### 17.4.1.21 Replication and MEMORY Tables

When a master server shuts down and restarts, its MEMORY tables become empty. To replicate this effect to slaves, the first time that the master uses a given MEMORY table after startup, it logs an event that notifies slaves that the table must be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its MEMORY tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.

- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating MEMORY tables is to first drop or delete all rows from the MEMORY tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its MEMORY tables will still be different from those on the master. This can be okay if the application logic is such that the contents of MEMORY tables can be safely lost (for example, if the MEMORY tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-MEMORY tables.

(The method just described is not applicable in NDB Cluster, where `slave_exec_mode` is always IDEMPOTENT, and cannot be changed.)

The size of MEMORY tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 17.4.1.38, "Replication and Variables"). A change in `max_heap_table_size` takes effect for MEMORY tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all MEMORY tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with Table is full errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 16.3, "The MEMORY Storage Engine", for more information about MEMORY tables.
17.4.1.22 Replication of the mysql System Schema

Data modification statements made to tables in the mysql schema are replicated according to the value of binlog_format; if this value is MIXED, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as GRANT, REVOKE, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

17.4.1.23 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include DELETE or UPDATE statements that use LIMIT with no ORDER BY clause; see Section 17.4.1.18, “Replication and LIMIT”, for a detailed discussion of these.

17.4.1.24 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”).

Replication between tables having different partitioning is generally not supported. This because statements (such as ALTER TABLE ... DROP PARTITION) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

17.4.1.25 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the REPAIR TABLE statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use REPAIR TABLE to repair it, you should first stop replication (if it is still running) before using REPAIR TABLE, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

17.4.1.26 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. For example, a table column named rank on a MySQL 5.7 master that is replicating to a MySQL 8.0 slave could cause a problem because RANK is a reserved word beginning in MySQL 8.0.

Replication can fail in such cases with Error 1064 You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected.
Only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (``).

For listings of reserved words by MySQL version, see Reserved Words, in the MySQL Server Version Reference. For identifier quoting rules, see Section 9.2, “Schema Object Names”.

### 17.4.1.27 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”.

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the InnoDB redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 17.4.1.30, “Replication and Temporary Tables”. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

### 17.4.1.28 Slave Errors During Replication
If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

**Note**

If a temporary error is recorded in the slave's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the slave SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the slave, unless the slave SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

### 17.4.1.29 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.11, “Server SQL Modes”.

### 17.4.1.30 Replication and Temporary Tables

In MySQL 8.0, when `binlog_format` is set to `ROW` or `MIXED`, statements that exclusively use temporary tables are not logged on the master, and therefore the temporary tables are not replicated. Statements that involve a mix of temporary and nontemporary tables are logged on the master only for the operations on nontemporary tables, and the operations on temporary tables are not logged. This means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. For
more information about row-based replication and temporary tables, see Row-based logging of temporary tables.

When binlog_format is set to STATEMENT, operations on temporary tables are logged on the master and replicated on the slave, provided that the statements involving temporary tables can be logged safely using statement-based format. In this situation, loss of replicated temporary tables on the slave can be an issue. In statement-based replication mode, CREATE TEMPORARY TABLE and DROP TEMPORARY TABLE statements cannot be used inside a transaction, procedure, function, or trigger when GTIDs are in use on the server (that is, when the enforce_gtid_consistency system variable is set to ON). They can be used outside these contexts when GTIDs are in use, provided that autocommit=1 is set.

Because of the differences in behavior between row-based or mixed replication mode and statement-based replication mode regarding temporary tables, you cannot switch the replication format at runtime, if the change applies to a context (global or session) that contains any open temporary tables. For more details, see the description of the binlog_format option.

Safe slave shutdown when using temporary tables. In statement-based replication mode, temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a STOP SLAVE SQL_THREAD statement.
2. Use SHOW STATUS to check the value of the Slave_open_temp_tables variable.
3. If the value is not 0, restart the slave SQL thread with START SLAVE SQL_THREAD and repeat the procedure later.
4. When the value is 0, issue a mysqladmin shutdown command to stop the slave.

Temporary tables and replication options. By default, with statement-based replication, all temporary tables are replicated; this happens whether or not there are any matching --replicate-do-db, --replicate-do-table, or --replicate-wild-do-table options in effect. However, the --replicate-ignore-table and --replicate-wild-ignore-table options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replication slave always replicates a DROP TEMPORARY TABLE IF EXISTS statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a --replicate-wild-ignore-table option to match that prefix. For example, you might give all such tables names beginning with norep (such as norepmytable, norepyourtable, and so on), then use --replicate-wild-ignore-table=norep% to prevent them from being replicated.

17.4.1.31 Replication Retries and Timeouts

The global system variable slave_transaction_retries sets the maximum number of times for applier threads on a single-threaded or multithreaded replication slave to automatically retry failed transactions before stopping. Transactions are automatically retried when the SQL thread fails to execute them because of an InnoDB deadlock, or when the transaction's execution time exceeds the InnoDB innodb_lock_wait_timeout value. If a transaction has a non-temporary error that will prevent it from ever succeeding, it is not retried.

The default setting for slave_transaction_retries is 10, meaning that a failing transaction with an apparently temporary error is retried 10 times before the applier thread stops. Setting the variable
to 0 disables automatic retrying of transactions. On a multithreaded slave, the specified number of transaction retries can take place on all applier threads of all channels. The Performance Schema table `replication_applier_status` shows the total number of transaction retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column.

The process of retrying transactions can cause lag on a replication slave or on a Group Replication group member, which can be configured as a single-threaded or multithreaded slave. The Performance Schema table `replication_applier_status_by_worker` shows detailed information on transaction retries by the applier threads on a single-threaded or multithreaded slave. This data includes timestamps showing how long it took the applier thread to apply the last transaction from start to finish (and when the transaction currently in progress was started), and how long this was after the commit on the original master and the immediate master. The data also shows the number of retries for the last transaction and the transaction currently in progress, and enables you to identify the transient errors that caused the transactions to be retried. You can use this information to see whether transaction retries are the cause of replication lag, and investigate the root cause of the failures that led to the retries.

### 17.4.1.32 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. Set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also Section 17.4.1.14, “Replication and System Functions”.

### 17.4.1.33 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- **Half-applied transactions.** A transaction which updates non-transactional tables has applied some but not all of its changes.

- **Gaps.** A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multithreaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that binary logging (the `log_bin` system variable) and slave update logging (the `--log-slave-updates`) are also enabled.

- **Gap-free low-watermark position.** Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. This can only happen on multithreaded slaves. Enabling `slave_preserve_commit_order` does not prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.

2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. **KILL** of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multithreaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.

4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multithreaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.

5. **STOP SLAVE** when using a multithreaded slave. After issuing **STOP SLAVE**, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before **STOP SLAVE** completes, either an error happens, or another thread issues **KILL**, or the server restarts. In these cases, **STOP SLAVE** returns successfully.)

6. If the last transaction in the relay log is only half-received and the multithreaded slave coordinator has started to schedule the transaction to a worker, then **STOP SLAVE** waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.

7. **STOP SLAVE** when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and **STOP SLAVE** stops immediately. If the ongoing transaction is mixed, **STOP SLAVE** waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues **STOP SLAVE** return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.

2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.

3. **CHANGE MASTER TO** statements for that channel fail with an error, unless the applier threads are running and the **CHANGE MASTER TO** statement only sets receiver options.

4. If `mysqld` is started with **--relay-log-recovery**, no recovery is done for that channel, and a warning is printed.

5. If `mysqldump` is used with **--dump-slave**, it does not record the existence of gaps; thus it prints **CHANGE MASTER TO** with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

   After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use **--dump-slave**).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. **START SLAVE [SQL_THREAD]** always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before **START SLAVE**, and even if **START SLAVE** is used with **UNTIL** clauses. **START
SLAVE UNTIL SQL_AFTER_MTS_GAPS only applies as many transactions as needed in order to fill in the gaps. If START SLAVE is used with UNTIL clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

**Warning**

RESET SLAVE removes the relay logs and resets the replication position. Thus issuing RESET SLAVE on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

slave-preserve-commit-order ensures that there are no gaps. However, it is still possible that Exec_master_log_pos is just a gap-free low-watermark position in scenarios 1 to 4 above. That is, there may be transactions after Exec_master_log_pos which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when slave-preserve-commit-order is enabled.

### 17.4.1.34 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the binlog_direct_non_transactional_updates system variable. When this variable is OFF (the default), logging is as just described. When this variable is ON, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. binlog_direct_non_transactional_updates has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that references both nontransactional and transactional tables and updates any of the tables involved is considered a “mixed” statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than REPEATABLE_READ

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
Updates a nontransactional table and `binlog_direct_non_transactional_updates` is OFF

For more information, see Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”.

**Note**

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

It is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** The `binlog_format` and `binlog_checksum` system variables are read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. This is even true for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

**Note**

For restrictions that apply specifically to XA transactions, see Section C.6, “Restrictions on XA Transactions”.

**17.4.1.35 Replication and Triggers**

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-
side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 8.0 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), and multiple triggers are permitted.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Multiple triggers are not supported in versions earlier than MySQL 5.7. If you upgrade servers in a replication topology that use a version earlier than MySQL 5.7, upgrade the replication slaves first and then upgrade the master. If an upgraded replication master still has old slaves using MySQL versions that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions are in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see the Table Trigger Storage section of the MySQL Server Doxygen documentation, available at [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html).

- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table’s `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.

2. Drop all triggers for the table.

3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

**17.4.1.36 Replication and TRUNCATE TABLE**

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB`
Replication Features and Issues

and other transactional tables on replication slaves still follow the rules described in Section 13.1.37, “TRUNCATE TABLE Syntax” governing such tables. (Bug #36763)

17.4.1.37 Replication and User Name Length

The maximum length of MySQL user names is 32 characters. Replication of user names longer than 16 characters to a slave earlier than MySQL 5.7 that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

17.4.1.38 Replication and Variables

System variables are not replicated correctly when using STATEMENT mode, except for the following variables when they are used with session scope:

- auto_increment_increment
- auto_increment_offset
- character_set_client
- character_set_connection
- character_set_database
- character_set_server
- collation_connection
- collation_database
- collation_server
- foreign_key_checks
- identity
- last_insert_id
- lc_time_names
- pseudo_thread_id
- sql_auto_is_null
- time_zone
- timestamp
- unique_checks

When MIXED mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.4.4.3, “Mixed Binary Logging Format”.

sql_mode is also replicated except for the NO_DIR_IN_CREATE mode; the slave always preserves its own value for NO_DIR_IN_CREATE, regardless of changes to it on the master. This is true for all replication formats.

However, when mysqlbinlog parses a SET @@sql_mode = mode statement, the full mode value, including NO_DIR_IN_CREATE, is passed to the receiving server. For this reason, replication of such a statement may not be safe when STATEMENT mode is in use.
The `default_storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 17.4.1.21, "Replication and MEMORY Tables".

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```sql
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```sql
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 17.2.1, “Replication Formats”.

The following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

**Important**

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems. The `lower_case_table_names` setting can only be configured when initializing the server.
17.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error.

17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.6 to a slave running MySQL 5.7, from a master running MySQL 5.7 to a slave running MySQL 8.0, and so on. However, you might encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, foreign key names longer than 64 characters are no longer supported from MySQL 8.0.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 8.0.1, MySQL 8.0.2, and MySQL 8.0.4 concurrently, although you could use any two of these releases together.

Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

From MySQL 8.0.14, the server version is recorded in the binary log for each transaction for the server that originally committed the transaction (original_server_version), and for the server that is the immediate master of the current server in the replication topology (immediate_server_version).

Replication from newer masters to older slaves might be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

  This also has significant implications for upgrading replication servers; see Section 17.4.3, “Upgrading a Replication Setup”, for more information.

- For more information about row-based replication, see Section 17.2.1, “Replication Formats”.

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

  However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.
17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see Section 2.11, “Upgrading MySQL”.

When you upgrade a master to 8.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 8.0.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 8.0.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 8.0 format.

Changes affecting operations in strict SQL mode (\texttt{STRICT\_TRANS\_TABLES} or \texttt{STRICT\_ALL\_TABLES}) may result in replication failure on an upgraded slave. If you use statement-based logging (\texttt{binlog\_format=STATEMENT}), if a slave is upgraded before the master, the nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (\texttt{binlog\_format=ROW}) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

The default character set has changed from \texttt{latin1} to \texttt{utf8mb4} in MySQL 8.0. In a replicated setting, when upgrading from MySQL 5.7 to 8.0, it is advisable to change the default character set back to the character set used in MySQL 5.7 before upgrading. After the upgrade is completed, the default character set can be changed to \texttt{utf8mb4}. Assuming that the previous defaults were used, one way to preserve them is to start the server with these lines in the \texttt{my.cnf} file:

```
[mysqld]
character_set_server=latin1
collation_server=latin1\_swedish\_ci
```

After the slaves have been upgraded, shut down the master, upgrade it to the same 8.0.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 8.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 8.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 8.0 format. These too are recognized by the 8.0 slaves.

In other words, when upgrading to MySQL 8.0, the slaves must be MySQL 8.0 before you can upgrade the master to 8.0. Note that downgrading from 8.0 to older versions does not work so simply: You must ensure that any 8.0 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at Section 2.11.4, “Changes in MySQL 8.0”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the \texttt{--skip-slave-start} option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of \texttt{REPAIR TABLE} or \texttt{ALTER TABLE}, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = OFF` statement. Alternatively, stop the master and restart it with the `--skip-log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set `sql_log_bin` to `OFF` earlier, execute a `SET sql_log_bin = ON` statement. If you restarted the master to disable the binary log, restart it without `--skip-log-bin`, and without `--skip-networking` so that clients and slaves can connect.

5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. See Section 17.1.3.4, “Setting Up Replication Using GTIDs”, which contains information about converting existing replication setups to use GTID-based replication.

Prior to MySQL 8.0.16, when the server is running with global transaction identifiers (GTIDs) enabled (gtid_mode=ON), do not enable binary logging by `mysql_upgrade` (the `--write-binlog` option). As of MySQL 8.0.16, the server performs the entire MySQL upgrade procedure, but disables binary logging during the upgrade, so there is no issue.

It is not recommended to load a dump file when GTIDs are enabled on the server (gtid_mode=ON), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

### 17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is check the error log for messages. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. Binary logging is enabled by default. If binary logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are not running the master with any settings that disable binary logging, such as the `--skip-log-bin` option.

- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.

- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.

- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Section 17.2.2, “Replication Implementation Details”. If the I/O thread state says `Connecting to master`, check the following:
How to Report Replication Bugs or Problems

- Verify the privileges for the user being used for replication on the master.
- Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is 3306). For the host name, ensure that the name resolves to the correct IP address.
- Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
- Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 17.4.1, “Replication Features and Issues”. If it is a bug, see Section 17.4.5, “How to Report Replication Bugs or Problems”, for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”.

  4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible
from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. This is not a replication problem. It is a problem of outside interference causing replication to fail.

2. Ensure that the slave is running with binary logging enabled (the log_bin system variable), and with the --log-slave-updates option enabled, which causes the slave to log the updates that it receives from the master into its own binary logs. These settings are the defaults.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
   - All binary log files from the master
   - All binary log files from the slave
   - The output of SHOW MASTER STATUS from the master at the time you discovered the problem
   - The output of SHOW SLAVE STATUS from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use mysqlbinlog to examine the binary logs. The following should be helpful to find the problem statement. log_file and log_pos are the Master_Log_File and Read_Master_Log_Pos values from SHOW SLAVE STATUS.

```shell
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, “How to Report Bugs or Problems”.

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated.
Group Replication Background

18.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server
individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided Group Communication System (GCS) protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication engine.

18.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

18.1.1.1 Primary-Secondary Replication

Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (master) and there is one or more secondaries (slaves). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

Figure 18.1 MySQL Asynchronous Replication

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has received the transaction. Only then does the Primary resume the commit operation.
Figure 18.2 MySQL Semisynchronous Replication

In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). Diagonal arrows represent messages exchanged between servers or messages exchanged between servers and the client application.

18.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-master update everywhere replication protocol. In essence, a replication group is formed by multiple servers and each server in the group may execute transactions independently. But all read-write (RW) transactions commit only after they have been approved by the group. Read-only (RO) transactions need no coordination within the group and thus commit immediately. In other words, for any RW transaction the group needs to decide whether it commits or not, thus the commit operation is not a unilateral decision from the originating server. To be precise, when a transaction is ready to commit at the originating server, the server atomically broadcasts the write values (rows changed) and the correspondent write set (unique identifiers of the rows that were updated). Then a global total order is established for that transaction. Ultimately, this means that all servers receive the same set of transactions in the same order. As a consequence, all servers apply the same set of changes in the same order, therefore they remain consistent within the group.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting the write sets of two different and concurrent transactions, in a process called certification. If two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The resolution procedure states that the transaction that was ordered first commits on all servers, whereas the transaction ordered second aborts, and thus is rolled back on the originating server and dropped by the other servers in the group. This is in fact a distributed first commit wins rule.
Finally, Group Replication is a shared-nothing replication scheme where each server has its own entire copy of the data.

The figure above depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

18.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state to a set of servers. Even if some of the servers subsequently fail, as long it is not all or a majority, the system is still available. Depending on the number of servers which fail the group might have degraded performance or scalability, but it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-master update everywhere nature ensures that even updates are not blocked in the event of a single server failure. To summarize, MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of a server crash, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue. For example see MySQL Router 8.0.

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

18.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- **Elastic Replication** - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
• **Highly Available Shards** - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.

• **Alternative to Master-Slave replication** - In certain situations, using a single master server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.

• **Autonomic Systems** - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

### 18.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

#### 18.1.3.1 Failure Detection

There is a failure detection mechanism provided that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

Suspictions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

#### 18.1.3.2 Group Membership

MySQL Group Replication relies on a group membership service. This is built into the plugin. It defines which servers are online and participating in the group. The list of online servers is often referred to as a view. Therefore, every server in the group has a consistent view of which are the members participating actively in the group at a given moment in time.

Servers have to agree not only on transaction commits, but also which is the current view. Therefore, if servers agree that a new server becomes part of the group, then the group itself is reconfigured to integrate that server in it, triggering a view change. The opposite also happens, if a server leaves the group, voluntarily or not, then the group dynamically rearranges its configuration and a view change is triggered.

Note though that when a member leaves voluntarily, it first initiates a dynamic group reconfiguration. This triggers a procedure, where all members have to agree on the new view without the leaving server. However, if a member leaves involuntarily (for example it has stopped unexpectedly or the network connection is down) then the failure detection mechanism realizes this fact and a reconfiguration of the group is proposed, this one without the failed member. As mentioned this requires agreement from the majority of servers in the group. If the group is not able to reach agreement (for example it partitioned in such a way that there is no majority of servers online), then the system is not be able to dynamically change the configuration and as such, blocks to prevent a split-brain situation. Ultimately, this means that the administrator needs to step in and fix this.

#### 18.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach
quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers \( n \) needed to tolerate \( f \) failures is then \( n = 2 \times f + 1 \).

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

<table>
<thead>
<tr>
<th>Majority Size</th>
<th>Failures Tolerated</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0</td>

<td>2</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
</tr>
</tbody>
</table>

The next Chapter covers technical aspects of Group Replication.

### 18.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three servers.

#### 18.2.1 Deploying Group Replication in Single-Primary Mode

Each of the server instances in a group can run on an independent physical machine, or on the same machine. This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently.
This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

18.2.1.1 Deploying Instances for Group Replication

The first step is to deploy three instances of MySQL Server. Group Replication is a built-in MySQL plugin provided with MySQL Server 8.0. For more background information on MySQL plugins, see Section 5.6, “MySQL Server Plugins”. This procedure assumes that MySQL Server was downloaded and unpacked into the directory named `mysql-8.0`. The following procedure uses one physical machine, therefore each MySQL server instance requires a specific data directory for the instance. Create the data directories in a directory named `data` and initialize each one.

```sh
mkdir data
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s1
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s2
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see Section 2.10.1, “Initializing the Data Directory”.

**Warning**

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see Section 18.5, “Group Replication Security”.
18.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see Section 18.8.2, “Group Replication Limitations”.

Group Replication Server Settings

To install and use the Group Replication plugin you must configure the MySQL Server instance correctly. It is recommended to store the configuration in the instance's configuration file. See Section 4.2.7, “Using Option Files” for more information. Unless stated otherwise, what follows is the configuration for the first instance in the group, referred to as s1 in this procedure. The following section shows an example server configuration.

```plaintext
[mysqld]
# server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-8.0/
port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

**Note**

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication requires a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```plaintext
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE
```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers, to allow execution of only statements that can be safely logged using a GTID, and to disable writing checksums for events written to the binary log.

If you are using a version of MySQL earlier than 8.0.3, where the defaults were improved for replication, you need to add these lines to the member’s option file.

```plaintext
log_bin=binlog
log_slave_updates=ON
binlog_format=ROW
master_info_repository=TABLE
relay_log_info_repository=TABLE
```
These settings instruct the server to turn on binary logging, use row-based format, to store replication metadata in system tables instead of files and disable binary log event checksums. For more details see Section 18.8.1, “Group Replication Requirements”.

Group Replication Settings

At this point the my.cnf file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
transaction_write_set_extraction=XXHASH64
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "127.0.0.1:24901"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
group_replication_bootstrap_group=off

```

- Configuring `transaction_write_set_extraction` instructs the server that for each transaction it has to collect the write set and encode it as a hash using the XXHASH64 hashing algorithm. From MySQL 8.0.2, this setting is the default, so this line can be omitted.

- Configuring `group_replication_group_name` tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa".

  The value of `group_replication_group_name` must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log. Use `SELECT UUID()` to generate a UUID.

- Configuring `group_replication_start_on_boot` instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the member is configured you can set `group_replication_start_on_boot` to on so that Group Replication starts automatically upon server boot.

- Configuring `group_replication_local_address` tells the plugin to use the network address 127.0.0.1 and port 24901 for internal communication with other members in the group.

**Important**

Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant). This address must be different to the hostname and port used for SQL and it must not be used for client applications. It must be reserved for internal communication between the members of the group while running Group Replication.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. From MySQL 8.0.14, IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses. A group can contain a mix of members using IPv6 and members using IPv4. For more information on Group Replication support for IPv6 networks and on mixed IPv4 and IPv6 groups, see Section 18.4.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”. 

The recommended port for `group_replication_local_address` is 33061. In this tutorial we use three server instances running on one machine, thus ports 24901 to 24903 are used for the internal communication network address. `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and as demonstrated in this tutorial, you can use the same host name or IP address for all members as long as the ports are all different.

- **Configuring `group_replication_group_seeds`** sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership information is listed at `performance_schema.replication_group_members`. Usually the `group_replication_group_seeds` list contains the hostname:port of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

  **Important**

  The hostname:port listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the SQL hostname:port used for client connections, and shown for example in `performance_schema.replication_group_members` table.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

  **Warning**

  When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they may not yet be in the group when contacted.

  It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

  Creating a group and joining multiple members at the same time is not supported. It may work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

A joining member must communicate with a seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address whitelisting for Group Replication, the whitelist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and whitelisted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a whitelisted address...
Deploying Group Replication in Single-Primary Mode

for the appropriate protocol, its connection attempt is refused. For more information, see Section 18.5.1, “IP Address Whitelisting”.

• Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not.

Important
This option must only be used on one server instance at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Disable this option after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

18.2.1.3 User Credentials

Group Replication uses the asynchronous replication protocol to achieve Section 18.10.5, “Distributed Recovery”, synchronizing group members before joining them to the group. The distributed recovery process relies on a replication channel named `group_replication_recovery` which is used to transfer transactions from donor members to members that join the group. Therefore you need to set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member recovery replication channels.

Start the server using the options file:

```bash
mysql-8.0/bin/mysqld --defaults-file=data/s1/s1.cnf
```

Create a MySQL user with the `REPLICATION-SLAVE` privilege. This process can be captured in the binary log and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. To disable binary logging, connect to server s1 and issue the following statements:

```sql
sql>
SET SQL_LOG_BIN=0;
```

In the following example the user `rpl_user` with the password `password` is shown. When configuring your servers use a suitable user name and password.

```sql
mysql> CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

If binary logging was disabled, enable it again once the user has been created.

```sql
mysql> SET SQL_LOG_BIN=1;
```

Once the user has been configured, use the `CHANGE MASTER TO` statement to configure the server to use the given credentials for the `group_replication_recovery` replication channel the next time it needs to recover its state from another member. Issue the following, replacing `rpl_user` and `password` with the values used when creating the user.
Deploying Group Replication in Single-Primary Mode

```sql
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \ 
   \ FOR CHANNEL 'group_replication_recovery';
```

Distributed recovery is the first step taken by a server that joins the group and does not have the same set of transactions as the group members. If these credentials are not set correctly for the `group_replication_recovery` replication channel and the `rpl_user` as shown, the server cannot connect to the donor members and run the distributed recovery process to gain synchrony with the other group members, and hence ultimately cannot join the group.

Similarly, if the server cannot correctly identify the other members via the server's `hostname` the recovery process can fail. It is recommended that operating systems running MySQL have a properly configured unique `hostname`, either using DNS or local settings. This `hostname` can be verified in the `Member_host` column of the `performance_schema.replication_group_members` table. If multiple group members externalize a default `hostname` set by the operating system, there is a chance of the member not resolving to the correct member address and not being able to join the group. In such a situation use `report_host` to configure a unique `hostname` to be externalized by each of the servers.

Using Group Replication and the Caching SHA-2 User Credentials Plugin

By default, users created in MySQL 8 use Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”. If the `rpl_user` you configure for distributed recovery uses the caching SHA-2 authentication plugin and you are not using Section 18.5.2, “Secure Socket Layer Support (SSL)” for the `group_replication_recovery` replication channel, RSA key-pairs are used for password exchange, see Section 6.4.3, “Creating SSL and RSA Certificates and Keys”. You can either copy the public key of the `rpl_user` to the member that should recover its state from the group, or configure the donors to provide the public key when requested.

The more secure approach is to copy the public key of the `rpl_user` to the member that should recover the group state from the donors. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the member joining the group with the path to the public key for the `rpl_user`.

Optionally, a less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the `rpl_user` to members when they join the group. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.

18.2.1.4 Launching Group Replication

Once server s1 has been configured and started, install the Group Replication plugin. Connect to the server and issue the following command:

```sql
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Important

The `mysql.session` user must exist before you can load Group Replication. `mysql.session` was added in MySQL version 8.0.2. If your data dictionary was initialized using an earlier version you must perform the MySQL upgrade procedure (see Section 2.11, “Upgrading MySQL”). If the upgrade is not run, Group Replication fails to start with the error message

```
There was an error when trying to access the server with user:
```

3263
To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
+----------------------------+----------+--------------------+----------------------+-------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Type</th>
<th>Library</th>
<th>License</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>PROPRIETARY</td>
</tr>
<tr>
<td>(...)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>group_replication</td>
<td>ACTIVE</td>
<td>GROUP REPLICATION</td>
<td>group_replication.so</td>
<td>PROPRIETARY</td>
</tr>
</tbody>
</table>
+----------------------------+----------+--------------------+----------------------|-------------+
```

To start the group, instruct server s1 to bootstrap the group and then start Group Replication. This bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the bootstrap configuration option was not saved in the configuration file. If it is saved in the configuration file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`.

```
SET GLOBAL group_replication_bootstrap_group=ON;
START GROUP_REPLICATION;
SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+---------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE  |
|---------------------------+--------------------------------------|-------------+-------------+---------------+
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | myhost      | 24801       | ONLINE        |
+---------------------------+--------------------------------------+-------------+-------------+---------------+
```

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `myhost` listening for client connections on port `24801`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
mysql> INSERT INTO t1 VALUES (1, 'Luis');
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
+----+------+
| c1 | c2   |
+----+------+
| 1  | Luis |
+----+------+
```
Deploying Group Replication in Single-Primary Mode

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log. The importance of the binary log entries is illustrated in the following section when the group grows and distributed recovery is executed as new members try to catch up and become online.

18.2.1.5 Adding Instances to the Group

At this point, the group has one member in it, server s1, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the location of the data directory, the ports that s2 is going to be listening on or its server_id. These different lines are highlighted in the listing below.

```ini
[mysqld]
# server configuration
data_dir=<full_path_to_data>/data/s2
basedir=<full_path_to_bin>/mysql-8.0/
port=24802
socket=<full_path_to_sock_dir>/s2.sock
#
# Replication configuration parameters
#server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE
#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "127.0.0.1:24902"
```

3265
Deploying Group Replication in Single-Primary Mode

```
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the option file in place you launch the server.

```
mysql-8.0/bin/mysqld --defaults-file=data/s2/s2.cnf
```

Then configure the recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. Issue the following statements on s2.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user '@%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user '@%';
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \
FOR CHANNEL 'group_replication_recovery';
```

**Tip**

If you are using the caching SHA-2 authentication plugin, the default in MySQL 8, see Using Group Replication and the Caching SHA-2 User Credentials Plugin.

Install the Group Replication plugin and start the process of joining the server to the group. The following example installs the plugin in the same way as used while deploying server s1.

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Add server s2 to the group.

```
mysql> START GROUP_REPLICATION;
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do not issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

**Tip**

When Group Replication starts successfully and the server joins the group it checks the `super_read_only` variable. By setting `super_read_only` to ON in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as read-write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when the `super_read_only` variable is set to ON then it is set to OFF upon joining the group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two ONLINE servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+-------------------------------+-------------+-------------+---------------+
| CHANNEL_NAME              | MEMBER_ID                     | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE  |
+---------------------------+-------------------------------+-------------+-------------+---------------+
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost      | 24801       | ONLINE       |
| group_replication_applier | ac39f3e6-6dfa-11e6-969d-00212844f856 | myhost      | 24802       | ONLINE       |
+---------------------------+-------------------------------+-------------+-------------+---------------+
```
As server s2 is also marked as ONLINE, it must have already caught up with server s1 automatically. Verify that it has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
+-----------------+
| Database (test) |
+-----------------+
| test            |
+-----------------+
```

```
mysql> SELECT * FROM test.t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 | Luis |
+----+------+
```

```
mysql> SHOW BINLOG EVENTS;
+---------------+------+----------------+-----------+-------------+--------------------------------------------------------------------+
| Log_name      | Pos  | Event_type     | Server_id | End_log_pos | Info                                                               |
+---------------+------+----------------+-----------+-------------+--------------------------------------------------------------------+
| binlog.000001 |  4   | Format_desc    |         2 |         123 | Server ver: 8.0.3-log, Binlog ver: 4                              |
| binlog.000001 | 123  | Previous_gtid  |         2 |         150 |                                                                    |
| binlog.000001 | 211  | Query          |         1 |         270 | BEGIN                                                              |
| binlog.000001 | 270  | View_change    |         1 |         369 | view_id=14724832985483517:1                                        |
| binlog.000001 | 369  | Query          |         1 |         434 | COMMIT                                                             |
| binlog.000001 | 434  | Gtid           |         1 |         495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:4'  |
| binlog.000001 | 495  | Query          |         1 |         585 | CREATE DATABASE test                                               |
| binlog.000001 | 585  | Gtid           |         1 |         646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:5'  |
| binlog.000001 | 646  | Query          |         1 |         770 | use 'test'; CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL) |
| binlog.000001 | 770  | Gtid           |         1 |         831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:6'  |
| binlog.000001 | 831  | Query          |         1 |         890 | BEGIN                                                              |
| binlog.000001 | 890  | Table_map      |         1 |         933 | table_id: 108 (test.t1)                                            |
| binlog.000001 | 933  | Write_rows     |         1 |         975 | table_id: 108 flags: STMT_END_F                                    |
| binlog.000001 | 975  | Xid            |         1 |        1002 | COMMIT /* xid=30 */                                                |
| binlog.000001 | 1002 | Gtid           |         1 |        1063 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:7'  |
| binlog.000001 | 1063 | Query          |         1 |        1122 | BEGIN                                                              |
| binlog.000001 | 1122 | View_change    |         1 |        1261 | view_id=14724832985483517:2                                        |
| binlog.000001 | 1261 | Query          |         1 |        1326 | COMMIT                                                             |
```

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. According to the distributed recovery procedure, this means that just after joining the group and immediately before being declared online, server s2 has connected to server s1 automatically and fetched the missing data from it. In other words, it copied transactions from the binary log of s1 that it was missing, up to the point in time that it joined the group.

**Adding Additional Instances**

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file

```
[
mysqld]
*
\# server configuration
datadir=<full_path_to_data>/data/s3
basedir=<full_path_to_bin>/mysql-8.0/
```
2. Start the server

```bash
mysql-8.0/bin/mysqld --defaults-file=data/s3/s3.cnf
```

3. Configure the recovery credentials for the `group_replication_recovery` channel.

```sql
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%;' ;
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \ 
FOR CHANNEL 'group_replication_recovery';
```

4. Install the Group Replication plugin and start it.

```sql
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```sql
mysql> SELECT * FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>CHANNEL_NAME</th>
<th>MEMBER_ID</th>
<th>MEMBER_HOST</th>
<th>MEMBER_PORT</th>
<th>MEMBER_STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_replication_applier</td>
<td>395409e1-6dfa-11e6-970b-00212844f856</td>
<td>myhost</td>
<td>24801</td>
<td>ONLINE</td>
</tr>
<tr>
<td>group_replication_applier</td>
<td>7eb217ff-6df3-11e6-966c-00212844f856</td>
<td>myhost</td>
<td>24803</td>
<td>ONLINE</td>
</tr>
<tr>
<td>group_replication_applier</td>
<td>ac39f1e6-6dfa-11e6-a69d-00212844f856</td>
<td>myhost</td>
<td>24802</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has also caught up:

```sql
mysql> SHOW DATABASES LIKE 'test';
```

```
<table>
<thead>
<tr>
<th>Database (test)</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
</tbody>
</table>
```
18.3 Monitoring Group Replication

Use the Performance Schema tables to monitor Group Replication, assuming that the Performance Schema is enabled. Group Replication adds the following tables:

- `performance_schema.replication_group_member_stats`
- `performance_schema.replication_group_members`

These Performance Schema replication tables also show information about Group Replication:

- `performance_schema.replication_connection_status` shows information regarding Group Replication, for example the transactions that have been received from the group and queued in the applier queue (the relay log).

- `performance_schema.replication_applier_status` shows the state of the Group Replication related channels and threads. If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

The replication channels created by the Group Replication plugin are named:

- `group_replication_recovery` - This channel is used for the replication changes that are related to the distributed recovery phase.

- `group_replication_applier` - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.
18.3.1 Group Replication Server States

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information could be reported, depending on which server is queried. If the server has left the group then it cannot report updated information about the other servers’ states. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Group Synchronized</th>
</tr>
</thead>
<tbody>
<tr>
<td>ONLINE</td>
<td>The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions.</td>
<td>Yes</td>
</tr>
<tr>
<td>RECOVERING</td>
<td>The member is in the process of becoming an active member of the group and is currently going through the recovery process, receiving state information from a donor.</td>
<td>No</td>
</tr>
<tr>
<td>OFFLINE</td>
<td>The plugin is loaded but the member does not belong to any group.</td>
<td>No</td>
</tr>
<tr>
<td>ERROR</td>
<td>The state of the member. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.</td>
<td>No</td>
</tr>
<tr>
<td>UNREACHABLE</td>
<td>Whenever the local failure detector suspects that a given server is not reachable, because for example it was disconnected involuntarily, it shows that server's state as UNREACHABLE.</td>
<td>No</td>
</tr>
</tbody>
</table>

Important

Once an instance enters ERROR state, the super_read_only option is set to ON. To leave the ERROR state you must manually configure the instance with super_read_only=OFF.

Note that Group Replication is not synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

18.3.2 The replication_group_members Table

The performance_schema.replication_group_members table is used for monitoring the status of the different server instances that are members of the group. The information in the table is updated whenever there is a view change, for example when the configuration of the group is dynamically changed when a new member joins. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. This table can be used to get a high level view of the state of a replication group, for example by issuing:
Based on this result we can see that the group consists of three members, each member’s host and port number which clients use to connect to the member, and the server_uuid of the member. The MEMBER_STATE column shows one of the Section 18.3.1, “Group Replication Server States”, in this case it shows that all three members in this group are ONLINE, and the MEMBER_ROLE column shows that there are two secondaries, and a single primary. Therefore this group must be running in single-primary mode. The MEMBER_VERSION column can be useful when you are upgrading a group and are combining members running different MySQL versions. See Section 18.3.1, “Group Replication Server States” for more information.

For more information about the Member_host value and its impact on the distributed recovery process, see Section 18.2.1.3, “User Credentials”.

### 18.3.3 Replication_group_member_stats

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The performance_schema.replication_group_member_stats table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the group_replication_flow_control_period option, so these can differ slightly from the locally collected statistics for the member where the query is made.

#### Table 18.2 replication_group_member_stats

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Channel_name</td>
<td>The name of the Group Replication channel.</td>
</tr>
<tr>
<td>View_id</td>
<td>The current view identifier for this group.</td>
</tr>
<tr>
<td>Member_id</td>
<td>The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.</td>
</tr>
<tr>
<td>Count_transactions_in_queue</td>
<td>The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.</td>
</tr>
<tr>
<td>Count_transactions_checked</td>
<td>The number of transactions that have been checked for conflicts.</td>
</tr>
<tr>
<td>Count_conflicts_detected</td>
<td>The number of transactions that did not pass the conflict detection check.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Count_transactions_rows_validating</td>
<td>The current size of the conflict detection database (against which each transaction is certified).</td>
</tr>
<tr>
<td>Transactions_committed_all_members</td>
<td>The transactions that have been successfully committed on all members of the replication group. This is updated at a fixed time interval.</td>
</tr>
<tr>
<td>Last_conflict_free_transaction</td>
<td>The transaction identifier of the last conflict free transaction checked.</td>
</tr>
<tr>
<td>Count_transactions_remote_in_applier_queue</td>
<td>The number of transactions that this member has received from the replication group which are waiting to be applied.</td>
</tr>
<tr>
<td>Count_transactions_remote_applied</td>
<td>The number of transactions that this member has received from the replication group which have been applied.</td>
</tr>
<tr>
<td>Count_transactions_local_proposed</td>
<td>The number of transactions that this member originated and sent to the replication group for coordination.</td>
</tr>
<tr>
<td>Count_transactions_local.rollback</td>
<td>The number of transactions that this member originated that were rolled back after being sent to the replication group.</td>
</tr>
</tbody>
</table>

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group’s members is delayed and is not able to keep up to date with the other members of the group. In this case you might see a large number of transactions in the queue. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin.

### 18.4 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups.

#### 18.4.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode
- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or MySQL Router 8.0.

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-primary mode:

- If a transaction is executed under the SERIALIZABLE isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.
These checks can be deactivated by setting the option `group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option must be set to `FALSE`.

### 18.4.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (with `super-read-only=ON`). This happens automatically. The primary is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

**Figure 18.5 New Primary Election**

When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single server writes to the group. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode they are not. Upon primary member failure, an automatic primary election mechanism chooses the new primary member. The election process is performed by looking at the new view, and ordering the potential new primaries based on the value of `group_replication_member_weight`. Assuming the group is operating with all members running the same MySQL version, then the member with the highest value for `group_replication_member_weight` is elected as the new primary. In the event that multiple servers have the same `group_replication_member_weight`, the servers are then prioritized based on their `server_uuid` in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-write and the other secondaries remain as secondaries, and as such, read-only.

When a new primary is elected, it is only writable once it has processed all of the transactions that came from the old primary. This avoids possible concurrency issues between old transactions from the old primary and the new ones being executed on this member. It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing client applications to it.

If the group is operating with members that are running different versions of MySQL then the election process can be impacted. For example, if any member does not support `group_replication_member_weight`, then the primary is chosen based on `server_uuid` order from the members of the lower major version. Alternatively, if all members running different MySQL versions do support `group_replication_member_weight`, the primary is chosen based on `group_replication_member_weight` from the members of the lower major version.

### 18.4.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure because there is no server playing any special role.
18.4.1.3 Finding the Primary

To find out which server is currently the primary when deployed in single-primary mode, use the MEMBER_ROLE column in the performance_schema.replication_group_members table. For example:

```
mysql> SELECT MEMBER_HOST, MEMBER_ROLE FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>MEMBER_HOST</th>
<th>MEMBER_ROLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote1.example.com</td>
<td>PRIMARY</td>
</tr>
<tr>
<td>remote2.example.com</td>
<td>SECONDARY</td>
</tr>
<tr>
<td>remote3.example.com</td>
<td>SECONDARY</td>
</tr>
</tbody>
</table>

**Warning**

The group_replication_primary_member status variable has been deprecated and is scheduled to be removed in a future version.

Alternatively use the group_replication_primary_member status variable.

```
mysql> SHOW STATUS LIKE 'group_replication_primary_member'
```

18.4.2 Configuring an Online Group

You can configure an online group while Group Replication is running by using a set of UDFs, which rely on a group action coordinator. These UDFs are installed by the Group Replication plugin in version 8.0.13 and higher. This section describes how changes are made to a running group, and the available UDFs.

**Important**

For the coordinator to be able to configure group wide actions on a running group, all members must be running MySQL 8.0.13 or later and have the UDFs installed.

To use the UDFs, connect to a member of the running group and issue the UDF with the `SELECT` statement. The Group Replication plugin processes the action and its parameters and the coordinator sends it to all members which are visible to the member where you issued the UDF. If the action is
accepted, all members execute the action and send a termination message when completed. Once all members declare the action as finished, the invoking member returns the result to the client.

When configuring a whole group, the distributed nature of the operations means that they interact with many processes of the Group Replication plugin, and therefore you should observe the following:

**You can issue configuration operations everywhere.** If you want to make member A the new primary you do not need to invoke the operation on member A. All operations are sent and executed in a coordinated way on all group members. Also, this distributed execution of an operation has a different ramification: if the invoking member dies, any already running configuration process continues to run on other members. In the unlikely event that the invoking member dies, you can still use the monitoring features to ensure other members complete the operation successfully.

**All members must be online.** To simplify the migration or election processes and guarantee they are as fast as possible, the group must not contain any member in recovery, otherwise the configuration action is rejected by the member where you issue the statement.

**No members can join a group during a configuration change.** Any member that attempts to join the group during a coordinated configuration change leaves the group and cancels its join process.

**Only one configuration at once.** A group which is executing a configuration change cannot accept any other group configuration change, because concurrent configuration operations could lead to member divergence.

**You cannot use configuration functions on mixed version groups.** Due to the distributed nature of these configuration actions, all members must recognize them in order to execute them. Therefore, no server of an older version can be present in the group, otherwise the operation is rejected.

### 18.4.2.1 Changing a Group’s Primary Member

This section explains how to change which member of a single-primary group is the primary. The function used to change a group's mode can be run on any member.

**Changing which Member is Primary**

Use the `group_replication_set_as_primary()` UDF to change which member is the primary in a single-primary group. This function has no effect if issued on a member of a multi-primary group. Only a primary member can write to the group, so if an asynchronous channel is running on that member, no switch is allowed until the asynchronous channel is stopped. Pass in the `server_uuid` of the member which you want to become the new primary of the group by issuing:

```sql
SELECT group_replication_set_as_primary(member_uuid);
```

While the action runs, you can check its progress by issuing:

```sql
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name LIKE '%stage/group_rpl%';
```

### 18.4.2.2 Changing a Group’s Mode

This section explains how to change the mode which a group is running in, either single or multi-primary. The functions used to change a group's mode can be run on any member.

**Changing to Single-Primary Mode**
Configuring an Online Group

Use the `group_replication_switch_to_single_primary_mode()` UDF to change a group running in multi-primary mode to single-primary mode by issuing:

```
SELECT group_replication_switch_to_single_primary_mode()
```

If no string is passed in, the election of the new primary in the resulting single-primary group is controlled by the configured election weights, or UUID lexicographic order (see Section 18.4.1.1, “Single-Primary Mode”). While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name LIKE "%stage/group_rpl%";
```

+----------------------------------------------------------------------------+----------------+----------------+
| event_name                                                                 | work_completed | work_estimated |
| stage/group_rpl/Primary Switch: waiting for pending transactions to finish |              4 |             20 |
+----------------------------------------------------------------------------+----------------+----------------+

To override the election process and configure a specific member of the multi-primary group as the new primary in the process, get the `server_uuid` of the member and pass it to `group_replication_switch_to_single_primary_mode()`. For example issue:

```
SELECT group_replication_switch_to_single_primary_mode(member_uuid);
```

Changing to Multi-Primary Mode

Use the `group_replication_switch_to_multi_primary_mode()` UDF to change a group running in single-primary mode to multi-primary mode by issuing:

```
SELECT group_replication_switch_to_multi_primary_mode()
```

After some coordinated group operations to ensure the safety and consistency of your data, all members which belong to the group become primaries.

While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name LIKE "%stage/group_rpl%";
```

+----------------------------------------------------------------------+----------------+----------------+
| event_name                                                           | work_completed | work_estimated |
| stage/group_rpl/Multi-primary Switch: applying buffered transactions |              0 |              1 |
+----------------------------------------------------------------------+----------------+----------------+

18.4.2.3 Using Group Replication Group Write Consensus

This section explains how to inspect and configure the maximum number of consensus instances at any time for a group. This maximum is referred to as the event horizon for a group, and is the maximum number of consensus instances that the group can execute in parallel. This enables you to fine tune the performance of your Group Replication deployment. For example, the default value of 10 is suitable for a group running on a LAN, but for groups operating over a slower network such as a WAN, increase this number to improve performance.

Inspecting a Group's Write Concurrency

Use the `group_replication_get_write_concurrency()` UDF to inspect a group's event horizon value at runtime by issuing:

```
SELECT group_replication_get_write_concurrency();
```
Configuring a Group's Write Concurrency

Use the `group_replication_set_write_concurrency()` UDF to set the maximum number of consensus instances that the system can execute in parallel by issuing:

```
SELECT group_replication_set_write_concurrency(instances);
```

where `instances` is the new maximum number of consensus instances.

18.4.3 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is fault tolerant and configurable. The following section explains how recovery works and how to tune the settings.

Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

**Note**

A donor is picked randomly from the list of online members in the current view.

Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- **Purged data scenarios** - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.

- **Duplicated data** - If a server joining the group already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the server joining the group.

  One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.

- **Other errors** - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

**Note**

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.
Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

Number of Attempts

The number of attempts a server joining the group makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable. The following command sets the maximum number of attempts to connect to a donor to 10.

```sql
mysql> SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the server joining the group makes connecting to each one of the suitable donors.

Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```sql
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the server joining the group is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A does not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the server joining the group has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

18.4.4 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.
Network Partitioning

Note
Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

Tip
A primary that has been excluded from a group after a majority loss followed by a reconfiguration can contain extra transactions that are not included in the new group. If this happens, the attempt to add back the excluded member from the group results in an error with the message This member has more executed transactions than those present in the group.

Detecting Partitions
The replication_group_members performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status UNREACHABLE for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.
To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier 199b2df7-4aaf-11e6-bb16-28b2bd168d07
- Server s2 with member identifier 199bb88e-4aaf-11e6-babe-28b2bd168d07
- Server s3 with member identifier 1999b9fb-4aaf-11e6-bb54-28b2bd168d07
- Server s4 with member identifier 19ab72fc-4aaf-11e6-bb51-28b2bd168d07
- Server s5 with member identifier 19b33846-4aaf-11e6-ba81-28b2bd168d07
Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+--------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
|---------------------------+--------------------------------------+-------------+-------------+--------------+
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   | 13002       | ONLINE       |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE       |
| group_replication_applier | 199b88e-4aaf-11e6-babe-28b2bd168d07  | 127.0.0.1   | 13000       | ONLINE       |
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1   | 13003       | ONLINE       |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1   | 13004       | ONLINE       |
+---------------------------+--------------------------------------+-------------+-------------+--------------+
```

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+--------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
|---------------------------+--------------------------------------+-------------+-------------+--------------+
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   | 13002       | UNREACHABLE  |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE       |
| group_replication_applier | 199b88e-4aaf-11e6-babe-28b2bd168d07  | 127.0.0.1   | 13000       | ONLINE       |
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1   | 13003       | UNREACHABLE  |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1   | 13004       | UNREACHABLE  |
+---------------------------+--------------------------------------+-------------+-------------+--------------+
```

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

### Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could chose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.
Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

**Warning**

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```sql
mysql> SELECT * FROM performance_schema.replication_group_members;
```
The first thing to do is to check what is the peer address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
+-----------------------------------+
| @@group_replication_local_address |
| 127.0.0.1:10000                   |
+-----------------------------------+
```

Then log in to s2 and do the same thing:

```
mysql> SELECT @@group_replication_local_address;
+-----------------------------------+
| @@group_replication_local_address |
| 127.0.0.1:10001                   |
+-----------------------------------+
```

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check `replication_group_members` on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+--------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
+---------------------------+--------------------------------------+-------------+-------------+--------------+
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1   | 13000       | ONLINE       |
| group_replication_applier | b60907e7-4ab6-11e6-af8b-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE       |
+---------------------------+--------------------------------------+-------------+-------------+--------------+
```

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+--------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
+---------------------------+--------------------------------------+-------------+-------------+--------------+
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1   | 13000       | ONLINE       |
| group_replication_applier | b60907e7-4ab6-11e6-af8b-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE       |
+---------------------------+--------------------------------------+-------------+-------------+--------------+
```

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial
split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

### 18.4.5 Support For IPv6 And For Mixed IPv6 And IPv4 Groups

From MySQL 8.0.14, Group Replication group members can use IPv6 addresses as an alternative to IPv4 addresses for communications within the group. To use IPv6 addresses, the operating system on the server host and the MySQL Server instance must both be configured to support IPv6. For instructions to set up IPv6 support for a server instance, see Section 5.1.12, “IPv6 Support”.

IPv6 addresses, or host names that resolve to them, can be specified as the network address that the member provides in the `group_replication_local_address` option for connections from other members. When specified with a port number, an IPv6 address must be specified in square brackets, for example:

```plaintext
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

The network address or host name specified in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. The address or host name specified as the Group Replication local address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. For the purpose of IP address whitelisting for Group Replication (see Section 18.5.1, “IP Address Whitelisting”), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_whitelist` option on the other servers in the replication group.

A replication group can contain a combination of members that present an IPv6 address as their Group Replication local address, and members that present an IPv4 address. When a server joins such a mixed group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 Group Replication local address, or the reverse, you must also set up and whitelist an alternative address for the joining member for the required protocol (or a host name that resolves to an address for that protocol). If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. The alternative address or host name only needs to be added to the `group_replication_ip_whitelist` option on the other servers in the replication group, not to the `group_replication_local_address` value for the joining member (which can only contain a single address).

For example, server A is a seed member for a group, and has the following configuration settings for Group Replication, so that it is advertising an IPv6 address in the `group_replication_group_seeds` option:

```plaintext
group_replication_bootstrap_group=on
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B is a joining member for the group, and has the following configuration settings for Group Replication, so that it has an IPv4 Group Replication local address:

```plaintext
group_replication_bootstrap_group=off
```
Using MySQL Enterprise Backup with Group Replication

Server B also has an alternative IPv6 address 2001:db8:8b0:40:3d9c:cc43:e006:19e8. For Server B to join the group successfully, both its IPv4 Group Replication local address, and its alternative IPv6 address, must be listed in Server A’s whitelist, as in the following example:

```plaintext
```

As a best practice for Group Replication IP whitelisting, Server B (and all other group members) should have the same whitelist as Server A, unless security requirements demand otherwise.

If any or all members of a replication group are using an older MySQL Server version that does not support the use of IPv6 addresses for Group Replication, a member cannot participate in the group using an IPv6 address (or a host name that resolves to one) as its Group Replication local address. This applies both in the case where at least one existing member uses an IPv6 address and a new member that does not support this attempts to join, and in the case where a new member attempts to join using an IPv6 address but the group includes at least one member that does not support this. In each situation, the new member cannot join. To make a joining member present an IPv4 address for group communications, you can either change the value of `group_replication_local_address` to an IPv4 address, or configure your DNS to resolve the joining member's existing host name to an IPv4 address. After you have upgraded every group member to a MySQL Server version that supports IPv6 for Group Replication, you can change the `group_replication_local_address` value for each member to an IPv6 address, or configure your DNS to present an IPv6 address. Changing the value of `group_replication_local_address` takes effect only when you stop and restart Group Replication.

### 18.4.6 Using MySQL Enterprise Backup with Group Replication

This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup; the same technique can be used to quickly add a new member to a group. Generally, backing up a Group Replication member is no different to backing up a stand-alone MySQL instance. The recommended process is to use MySQL Enterprise Backup image backups and a subsequent restore, for more information see Backup Operations.

The required steps can be summarized as:

- Use MySQL Enterprise Backup to create a backup of the source server instance with simple timestamps.
- Copy the backup to the destination server instance.
- Use MySQL Enterprise Backup to restore the backup to the destination server instance.

The following procedure demonstrates this process. Consider the following group:

```
mysql> SELECT * member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>node2</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
<tr>
<td>node3</td>
<td>3306</td>
<td>ONLINE</td>
</tr>
</tbody>
</table>

In this example the group is operating in single-primary mode and the primary group member is node1. This means that node2 and node3 are secondaries, operating in read-only mode (super_read_only=ON). Using MySQL Enterprise Backup, a recent backup has been taken of node2 by issuing:
Using MySQL Enterprise Backup with Group Replication

```
mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
--backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -pmYsecr3t \
--host=127.0.0.1 --no-history-logging backup-to-image
```

The `--no-history-logging` option is used because `node2` is a secondary, and because it is read-only MySQL Enterprise Backup cannot write status and metadata tables to the instance.

Assume that the primary member, `node1`, encounters irreconcilable corruption. After a period of time the server instance is rebuilt but all the data on the member was lost. The most recent backup of member `node2` can be used to rebuild `node1`. This requires copying the backup files from `node2` to `node1` and then using MySQL Enterprise Backup to restore the backup to `node1`. The exact way you copy the backup files depends on the operating system and tools available to you. In this example we assume Linux servers and use SCP to copy the files between servers:

```
node2/backups# scp my.mbi_2206_1429 node1:/backups
```

Connect to the destination server, in this case `node1`, and restore the backup using MySQL Enterprise Backup by issuing:

```
mysqlbackup --defaults-file=/etc/my.cnf \
--backup-image=/backups/my.mbi_2206_1429 \ 
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

The backup is restored to the destination server.

If your group is using multi-primary mode, extra care must be taken to prevent writes to the database during the MySQL Enterprise Backup restore stage and the Group Replication recovery phase. Depending on how the group is accessed by clients, there is a possibility of DML being executed on the newly joined instance the moment it is accessible on the network, even prior to applying the binary log before rejoining the group. To avoid this, configure the member's option file with:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

This ensures that Group Replication is not started on boot, that the member defaults to read-only and that the `event_scheduler` is turned off while the member catches up with the group during the recovery phase. Adequate error handling must be configured on the clients to recognise that they are, temporarily, prevented from performing DML during this period.

Start the server instance and connect an SQL client. The restored backup has old binary log files and related metadata that are specific to the instance that was backed up. To reset all of that issue:

```
mysql> RESET MASTER;
```

The restored backup has the relay log files associated with the source instance, in this case `node2`. Therefore reset the logs, metadata, and configuration for all replication channels by issuing:

```
m.mysql> RESET SLAVE ALL;
```

For the restored instance to be able to be able to recover automatically using Group Replication's built-in distributed recovery (see Section 18.10.5, “Distributed Recovery”), configure the `gtid_executed` variable. The MySQL Enterprise Backup backup from `node2` includes the `backup_gtid_executed.sql` file, usually at the path `datadir/meta/`, which contains the information required to configure `node1`. Disable binary logging and then use this file to configure the `gtid_executed` variable by issuing:

```
m.mysql> SET SQL_LOG_BIN=OFF;
m.mysql> SOURCE datadir/meta/backup_gtid_executed.sql
m.mysql> SET SQL_LOG_BIN=ON;
```
Configure the Section 18.2.1.3, “User Credentials” and start Group Replication, for example:

```sql
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' /
    FOR CHANNEL 'group_replication_recovery';
```

The instance attempts to join the group, executing the restored binary logs from the correct location. Once the instance gains synchrony with the group, it joins as a secondary, with `super_read_only=ON`. Reset the temporary configuration changes made during the restore. Turn the event scheduler back on in the running process:

```sql
mysql> SET global event_scheduler=ON;
```

Edit the following system variables in the instance's option file:

```
group_replication_start_on_boot=ON
super_read_only=ON
event_scheduler=ON
```

## 18.5 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using address whitelisting.

### 18.5.1 IP Address Whitelisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication System connection can be accepted. This option is called `group_replication_ip_whitelist`. If you set this option on a server s1, then when server s2 is establishing a connection to s1 for the purpose of engaging group communication, s1 first checks the whitelist before accepting the connection from s2. If s2 is in the whitelist, then s1 accepts the connection, otherwise s1 rejects the connection attempt by s2.

If you do not specify a whitelist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 and (from MySQL 8.0.14) IPv6 are used to create an automatic Group Replication whitelist. The automatic whitelist therefore includes any IP addresses found for the host in the following ranges:

IPv4 (as defined in RFC 1918)
- 10/8 prefix (10.0.0.0 - 10.255.255.255) - Class A
- 172.16/12 prefix (172.16.0.0 - 172.31.255.255) - Class B
- 192.168/16 prefix (192.168.0.0 - 192.168.255.255) - Class C

IPv6 (as defined in RFC 4193 and RFC 5156)
- fc00::/7 prefix - unique-local addresses
- fe80::/10 prefix - link-local unicast addresses
- 127.0.0.1 - localhost for IPv4
- ::1 - localhost for IPv6

An entry is added to the error log stating the addresses that have been whitelisted automatically for the host.

The automatic whitelist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group
Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit whitelist. If you specify any entries for the whitelist, the private and localhost addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify a whitelist manually, use the `group_replication_ip_whitelist` option. You cannot change the whitelist on a server while it is an active member of a replication group. If the member is active, you must issue a `STOP GROUP_REPLICATION` statement before changing the whitelist, and a `START GROUP_REPLICATION` statement afterwards.

In the whitelist, you can specify any combination of the following:

- IPv4 addresses (for example, 198.51.100.44)
- IPv4 addresses with CIDR notation (for example, 192.0.2.21/24)
- IPv6 addresses, from MySQL 8.0.14 (for example, 2001:db8:85a3:8d3:1319:8a2e:370:7348)
- IPv6 addresses with CIDR notation, from MySQL 8.0.14 (for example, 2001:db8:85a3:8d3::/64)
- Host names (for example, example.org)
- Host names with CIDR notation (for example, www.example.com/24)

Before MySQL 8.0.14, host names could only resolve to IPv4 addresses. From MySQL 8.0.14, host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to whitelist a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

You must stop and restart Group Replication on a member in order to change its whitelist. A comma must separate each entry in the whitelist. For example:

```sql
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3::/64,example.org,www.example.com/24";
mysql> START GROUP_REPLICATION;
```

The whitelist must contain the IP address or host name that is specified in each member's `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. If a host name used as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is preferred for Group Replication connections.

To join a replication group, a server needs to be whitelisted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `group_replication_group_seeds` option in the configuration for the server joining the group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and whitelist an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). This is because when a server joins a replication group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. For more information on managing mixed IPv4 and IPv6 replication groups, see Section 18.4.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.
When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only whitelisted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not whitelist it. To avoid this scenario entirely, specify the same whitelist for all servers that are members of the replication group.

**Note**

It is possible to configure different whitelists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different whitelists to meet your security requirements, ensure that there is sufficient overlap between the whitelists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for whitelist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

**Warning**

Host names are inherently less secure than IP addresses in a whitelist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

### 18.5.2 Secure Socket Layer Support (SSL)

MySQL Group Replication supports OpenSSL and wolfSSL builds of MySQL Server.

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

#### Configuring SSL for Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the server joining the group establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the server joining the group connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```sql
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the server joining the group to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```sql
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '.../cacert.pem';
```
Secure Socket Layer Support (SSL)

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```sql
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '.../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '.../client-key.pem';
```

```sql
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
new_member> START GROUP_REPLICATION;
```

### Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server’s SSL configuration. As such, if the server has SSL configured, the Group Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see Section 6.4.2, “Command Options for Encrypted Connections”. The options which configure Group Replication are shown in the following table.

#### Table 18.3 SSL Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$ssl_key</td>
<td>Path of key file. To be used as client and server certificate.</td>
</tr>
<tr>
<td>$ssl_cert</td>
<td>Path of certificate file. To be used as client and server certificate.</td>
</tr>
<tr>
<td>$ssl_ca</td>
<td>Path of file with SSL Certificate Authorities that</td>
</tr>
</tbody>
</table>
### Secure Socket Layer Support (SSL)

<table>
<thead>
<tr>
<th><strong>SSL Configuration</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ssl_capath</code></td>
<td>Path of directory containing certificates for SSL Certificate Authorities that are trusted.</td>
</tr>
<tr>
<td><code>ssl_crl</code></td>
<td>Path of file containing the certificate revocation lists.</td>
</tr>
<tr>
<td><code>ssl_crlpath</code></td>
<td>Path of directory containing revoked certificate lists.</td>
</tr>
<tr>
<td><code>ssl_cipher</code></td>
<td>Permitted ciphers to use while encrypting data over the connection.</td>
</tr>
<tr>
<td><code>tls_version</code></td>
<td>Secure communication will use this version and its protocols.</td>
</tr>
</tbody>
</table>
These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

### Table 18.4 `group_replication_ssl_mode` configuration values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISABLED</td>
<td>Establish an unencrypted connection (default).</td>
</tr>
<tr>
<td>REQUIRED</td>
<td>Establish a secure connection if the server supports secure connections.</td>
</tr>
<tr>
<td>VERIFY_CA</td>
<td>Like REQUIRED, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.</td>
</tr>
<tr>
<td>VERIFY_IDENTITY</td>
<td>Like VERIFY_CA, but additionally verify that the server certificate matches the host</td>
</tr>
</tbody>
</table>
The following example shows an example my.cnf file section used to configure SSL on a server and how activate it for Group Replication.

```ini
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/.../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/.../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

### 18.6 Upgrading Group Replication

This section explains how to upgrade a group replication setup. The basic process of upgrading members of a group is the same as upgrading stand-alone instances, see Section 2.11, “Upgrading MySQL” for the actual process of doing upgrade and types available. Choosing between an in-place or logical upgrade depends on the amount of data stored in the group. Usually an in-place upgrade is faster, and therefore is recommended. Due to the distributed nature of Group Replication, there are considerations such as what order to upgrade members of a group, which are described in this section. You should also consult Section 17.4.3, “Upgrading a Replication Setup”.

If your group can be taken fully offline see Section 18.6.1, “Group Replication Offline Upgrade”. If your group needs to remain online, as is common with production deployments, see Section 18.6.2, “Group Replication Online Upgrade” for the different approaches available for upgrading a group with minimal downtime.

#### 18.6.1 Group Replication Offline Upgrade

To perform an offline upgrade of a Group Replication group, you remove each member from the group, perform an upgrade of the member and then restart the group as usual. In a multi-primary group you can shutdown the members in any order. In a single-primary group, shutdown each secondary first and then finally the primary. See Section 18.6.2.3, “Upgrading a Group Replication Member” for how to remove members from a group and shutdown MySQL.

Once the group is offline, upgrade all of the members. See Section 2.11, “Upgrading MySQL” for how to perform an upgrade. When all members have been upgraded, restart the members.

#### 18.6.2 Group Replication Online Upgrade

When you have a group running which you want to upgrade but you need to keep the group online to serve your application, you need to consider your approach to the upgrade. This section describes the different elements involved in an online upgrade, and various methods of how to upgrade your group.
18.6.2.1 Online Upgrade Considerations

When upgrading an online group you should consider the following points:

- Regardless of the way which you upgrade your group, it is important to disable any writes to group members until they are ready to rejoin the group.

- When a member is stopped, the `super_read_only` variable is set to on automatically, but this change is not persisted.

- When MySQL 5.7.22 or MySQL 8.0.11 tries to join a group running MySQL 5.7.21 or lower it fails to join the group because MySQL 5.7.21 does not send its value of `lower_case_table_names`.

18.6.2.2 Combining Group Replication Versions

When you upgrade an online group, you might need to run different versions of MySQL on members in the group at the same time. Depending on the changes made between the versions of MySQL, you could encounter incompatibilities. For example, if a feature has been deprecated between major versions then combining the versions in a group might cause members which rely on the deprecated feature to fail. This section describes the best practices for combining members running different versions of MySQL in the same group.

Group Replication is versioned according to the server version which the plugin was bundled with, for example if a member is running MySQL 5.7.19 then that is the version of the plugin. This version number is critical when upgrading a group, and specifically at the time of joining members to a group. See Section 2.1.1, “Which MySQL Version and Distribution to Install”.

To check the version of MySQL on a group member issue:

```
SELECT MEMBER_HOST, MEMBER_PORT, MEMBER_VERSION FROM performance_schema.replication_group_members;
```

<table>
<thead>
<tr>
<th>member_host</th>
<th>member_port</th>
<th>member_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>example.com</td>
<td>3306</td>
<td>8.0.13</td>
</tr>
</tbody>
</table>

The rules for combining members in a group with different major versions are:

- You cannot join a member to a group when it is running an older major version than the major version which the existing group members are running. For example if you have a group with members running MySQL version 8.0, you cannot add a member which is running an older version such as MySQL version 5.7.

- You can join a member to group if it is running a newer major version than the major version which the existing group members are running. For example if you have a group with members running MySQL 5.7, you can add a member running MySQL version 8.0, but it remains in read-only mode. Writing to this member while there are read-write members running an older MySQL version is dangerous and must be avoided.

The rules for combining members in a group with different minor versions are:

- You can add members running a newer or older minor version to a group, they are able to do writes. In a single-primary group, added members default to being read-only.

18.6.2.3 Upgrading a Group Replication Member

This section explains the steps required for upgrading a member of a group. This procedure is part of the methods described at Section 18.6.2.4, “Group Replication Online Upgrade Methods”. The process of
upgrading a member of a group is common to all methods and is explained first. The way which you join upgraded members can depend on which method you are following, and other factors such as whether the group is operating in single-primary or multi-primary mode. How you upgrade the server instance, using either the in-place or provision approach, does not impact on the methods described here.

The process of upgrading a member consists of removing it from the group, following your chosen method of upgrading the member, and then rejoining the upgraded member to a group. The recommended order of upgrading members in a single-primary group is to upgrade all secondaries, and then upgrade the primary last. If the primary is upgraded before a secondary, a new primary using the older MySQL version is chosen, but there is no need for this step.

To upgrade a member of a group:

• Connect a client to the group member and issue `STOP GROUP_REPLICATION`. Before proceeding, ensure that the member’s status is `OFFLINE` by monitoring the `replication_group_members` table.

• Disable Group Replication from starting up automatically so that you can safely connect to the member after upgrading and configure it without it rejoining the group by setting `group_replication_start_on_boot=0`.

  **Important**

  If an upgraded member has `group_replication_start_on_boot=1` then it could rejoin the group before you can perform the MySQL upgrade procedure and could result in issues. For example, if the upgrade fails and the server restarts again, then a possibly broken server could try to join the group.

• Stop the member, for example using `mysqladmin shutdown` or the `SHUTDOWN` statement. Any other members in the group continue running.

• Upgrade the member, using the in-place or provisioning approach. See Section 2.11, “Upgrading MySQL” for details. When restarting the upgraded member, because `group_replication_start_on_boot` is set to 0, Group Replication does not start on the instance, and therefore it does not rejoin the group.

• Once the MySQL upgrade procedure has been performed on the member, `group_replication_start_on_boot` must be set to 1 to ensure Group Replication starts correctly after restart. Restart the member.

• Connect to the upgraded member and issue `START GROUP_REPLICATION`. This rejoins the member to the group. The Group Replication metadata is in place on the upgraded server, therefore there is usually no need to reconfigure Group Replication. The server has to catch up with any transactions processed by the group while the server was offline. Once it has caught up with the group, it becomes an online member of the group.

  **Note**

  the longer it takes to upgrade a server, the more time that member is offline and therefore the more time it takes for the server to catch up when added back to the group.

When an upgraded member joins a group which has any member running an earlier version, the upgraded member joins with `super_read_only=on`, regardless of whether it was a primary or secondary. This ensures that no writes are made to upgraded members until all members are running the newer version. In a multi-primary group, once you are sure the upgrade has been successful and the group is ready to process transactions, it is necessary to manually configure members which should become writeable primaries. Connect to each member and issue:
SET GLOBAL read_only=off;

18.6.2.4 Group Replication Online Upgrade Methods

Choose one of the following methods of upgrading a Group Replication group:

Rolling In-Group Upgrade

This method is supported provided that servers running a newer major version are not generating workload to the group while there are still servers with an older version in it. In other words servers with a newer major version can join the group only as secondaries. In this method there is only ever one group, and each server instance is removed from the group, upgraded and then rejoined to the group. Members running the newer version join the group with `super_read_only=ON`. This method is well suited to single-primary groups. When the group is operating in single-primary mode, the primary member should be the last member to be upgraded. If the primary is upgraded while there are still members running the old version, a new primary is chosen from the members running the old version, but there is no need for this.

For groups operating in single-primary mode, once all secondaries are running the newer version, when the primary member leaves the group to be upgraded, a new primary is automatically chosen from the members running the new version. For groups operating in multi-primary mode, once all members are upgraded, you must manually set `super_read_only=OFF` on each member that should function as a primary. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Rolling Migration Upgrade

In this method you remove members from the group, upgrade them and then create a second group using the upgraded members. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are upgrading the members, you need the group running the newer version to catch up with any transactions executed while the members were being upgraded. Therefore one of the servers in the new group is configured as a replication slave of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of master-slave replication, see Chapter 17, Replication. For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- remove members from the original group running the older server version one by one, see Section 18.6.2.3, “Upgrading a Group Replication Member”
- upgrade the server version running on the member, see Section 2.11, “Upgrading MySQL”. You can either follow an in-place or provision approach to upgrading.
- create a new group with the upgraded members, see Chapter 18, Group Replication. In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see Section 17.1.3.4, “Setting Up Replication Using GTIDs”. Configure the older primary to function as the asynchronous replication master and the new group member as a GTID-based replication slave.
Before you can redirect your application to the new group, you must ensure that the new group has a suitable number of members, for example so that the group can handle the failure of a member. Issue

```
SELECT * FROM performance_schema.replication_group_members
```

and compare the initial group size and the new group size. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection and upgrade any missing members.

**Rolling Duplication Upgrade**

In this method you create a second group consisting of members which are running the newer version, and the data missing from the older group is replicated to the newer group. This assumes that you have enough servers to run both groups simultaneously. Due to the fact that during this process the number of primaries is *not* decreased, for groups operating in multi-primary mode there is no reduction in write availability. This makes rolling duplication upgrade well suited to groups operating in multi-primary mode. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are provisioning the members in the new group, you need the group running the newer version to catch up with any transactions executed while the members were being provisioned. Therefore one of the servers in the new group is configured as a replication slave of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of master-slave replication, see Chapter 17, *Replication*. For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- deploy a suitable number of members so that the group running the newer version can handle failure of a member
- take a backup of the existing data from a member of the group
- use the backup from the older member to provision the members of the new group, see Section 18.6.2.5, “Group Replication Upgrade with `mysqlbackup`” for one method.

```
Note
```

You must restore the backup to the same version of MySQL which the backup was taken from, and then perform an in-place upgrade. For instructions, see Section 2.11, “Upgrading MySQL”.

- create a new group with the upgraded members, see Chapter 18, *Group Replication*. In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see Section 17.1.3.4, “Setting Up Replication Using GTIDs”. Configure the older primary to function as the asynchronous replication master and the new group member as a GTID-based replication slave.

Once the ongoing data missing from the newer group is small enough to be quickly transferred, you must redirect write operations to the new group. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection.

**18.6.2.5 Group Replication Upgrade with `mysqlbackup`**

As part of a provisioning approach you can use MySQL Enterprise Backup to copy and restore the data from a group member to new members. However you cannot use this technique to directly restore a
backup taken from a member running an older version of MySQL to a member running a newer version of MySQL. The solution is to restore the backup to a new server instance which is running the same version of MySQL as the member which the backup was taken from, and then upgrade the instance. This process consists of:

- Take a backup from a member of the older group using `mysqlbackup`. See Section 18.4.6, “Using MySQL Enterprise Backup with Group Replication”.
- Deploy a new server instance, which must be running the same version of MySQL as the older member where the backup was taken.
- Restore the backup from the older member to the new instance using `mysqlbackup`.
- Upgrade MySQL on the new instance, see Section 2.11, “Upgrading MySQL”.

Repeat this process to create a suitable number of new instances, for example to be able to handle a failover. Then join the instances to a group based on the Section 18.6.2.4, “Group Replication Online Upgrade Methods”.

### 18.7 Group Replication System Variables

These are the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with “group_replication”.

---

**Important**

- Although most variables are described as dynamic and can be changed while the server is running, most changes only take effect upon restarting the Group Replication plugin. Variables which can be changed without requiring a restart of the plugin are specifically noted as such in this section.
- Variables that specify IP addresses or host names for group members are not validated until a `START GROUP_REPLICATION` statement is issued. The Group Communication System (GCS) is not available to validate the values until that point.
- A number of variables for Group Replication are not completely validated during server startup if they are passed as command line arguments to the server. These variables include `group_replication_group_name`, `group_replication_single_primary_mode`, `group_replication_force_members`, the SSL variables, and the flow control variables. They are only fully validated after the server has started.

---

<table>
<thead>
<tr>
<th>Property</th>

</tbody>
</table>
### Group Replication System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Removed in version 8.0.4. Allow the current server to join the group even if it has transactions not present in the group.

**Warning**

Use caution when enabling this option as incorrect usage could lead to inconsistencies in the group.

- `group_replication_allow_local_lower_version_join`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-allow-local-lower-version-join=value</code></td>
</tr>
<tr>

</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Allow the current server to join the group even if it has a lower plugin version than the group.

- `group_replication_auto_increment_increment`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-auto-increment-increment=value</code></td>
</tr>
<tr>
<td>System Variable</td>

</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>7</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Determines the interval between successive column values for transactions that execute on this server instance.

- `group_replication_bootstrap_group`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-bootstrap-group=value</code></td>
</tr>
</tbody>
</table>
Group Replication System Variables

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>group_replication_bootstrap_group</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to OFF. It should be set to OFF both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- group_replication_communication_debug_options

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--group-replication-communication-debug-options=value</td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.3</td>
</tr>
<tr>
<td>System Variable</td>
<td>group_replication_communication_debug_options</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>GCS_DEBUG_NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>GCS_DEBUG_NONE</td>
</tr>
<tr>
<td></td>
<td>GCS_DEBUG_BASIC</td>
</tr>
<tr>
<td></td>
<td>GCS_DEBUG_TRACE</td>
</tr>
<tr>
<td></td>
<td>XCOM_DEBUG_BASIC</td>
</tr>
<tr>
<td></td>
<td>XCOM_DEBUG_TRACE</td>
</tr>
<tr>
<td></td>
<td>GCS_DEBUG_ALL</td>
</tr>
</tbody>
</table>

Configures the level of debugging messages to provide for the different Group Replication components, such as Group Communication System (GCS) and the group communication engine (XCom, a Paxos variant). The debug information is stored in the GCS_DEBUG_TRACE file in the data directory.

The set of available options, specified as strings, can be combined. The following options are available:

- **GCS_DEBUG_NONE** disables all debugging levels for both GCS and XCOM
- **GCS_DEBUG_BASIC** enables basic debugging information in GCS
- **GCS_DEBUG_TRACE** enables trace information in GCS
**Group Replication System Variables**

- **XCOM_DEBUG_BASIC** enables basic debugging information in XCOM
- **XCOM_DEBUG_TRACE** enables trace information in XCOM
- **GCS_DEBUG_ALL** enables all debugging levels for both GCS and XCOM

Setting the debug level to **GCS_DEBUG_NONE** only has an effect when provided without any other option. Setting the debug level to **GCS_DEBUG_ALL** overrides all other options.

- **group_replication_components_stop_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--group-replication-components-stop-timeout=value</td>
</tr>
<tr>
<td>System Variable</td>
<td>group_replication_components_stop_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

Timeout, in seconds, that Group Replication waits for each of the components when shutting down.

- **group_replication_compression_threshold**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--group-replication-compression-threshold=value</td>
</tr>
<tr>
<td>System Variable</td>
<td>group_replication_compression_threshold</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The value in bytes above which (LZ4) compression is enforced. When set to zero, deactivates compression.

- **group_replication_consistency**
Group Replication System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.14</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_consistency</code></td>

<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>EVENTUAL</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>EVENTUAL</code> <code>BEFORE_ON_PRIMARY_FAILOVER</code> <code>BEFORE</code> <code>AFTER</code> <code>BEFORE_AND_AFTER</code></td>
</tr>
</tbody>
</table>

Controls the transaction consistency guarantee which a group provides. You can configure the consistency globally or per transaction. Also configures the fencing mechanism used by newly elected primaries in single primary groups. The effect of the variable must be considered for both read only (RO) and read write (RW) transactions. The following list shows the possible values of this variable, in order of increasing transaction consistency guarantee:

- **EVENTUAL**
  
  Both RO and RW transactions do not wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before this variable was added. A RW transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new RO and RW transactions before the previous primary transactions are all applied. RO transactions could result in outdated values, RW transactions could result in a rollback due to conflicts.

- **BEFORE_ON_PRIMARY_FAILOVER**

  New RO or RW transactions with a newly elected primary that is applying backlog from the old primary are held (not applied) until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but does depend on the size of the backlog.

- **BEFORE**

  A RW transaction waits for all preceding transactions to complete before being applied. A RO transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every RW transaction, by ensuring synchronization is used only on RO transactions.

- **AFTER**
A RW transaction waits until its changes have been applied to all of the other members. This value has no effect on RO transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly RO operations to ensure that applied RW transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every RO transaction, by ensuring synchronization is used only on RW transactions.

- **BEFORE_AND_AFTER**

  A RW transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A RO transaction waits for all preceding transactions to complete before execution takes place.

- **group_replication_enforce_update_everywhere_checks**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-enforce-update-everywhere-checks=value</code></td>
</tr>
<tr>

</tr>
<tr>
<td>Valid Values</td>
<td><code>READ_ONLY</code></td>
</tr>
</tbody>
</table>
Group Replication System Variables

Configures how Group Replication behaves when a server instance leaves the group unintentionally, for example after encountering an applier error, or in the case of a loss of majority, or when another member of the group expels it due to a suspicion timing out. The timeout period for a member to leave the group in the case of a loss of majority is set by the `group_replication_unreachable_majority_timeout` system variable, and the timeout period for suspicions is set by the `group_replication_member_expel_timeout` system variable. Note that an expelled group member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

When `group_replication_exit_state_action` is set to `ABORT_SERVER`, if the member exits the group unintentionally, the instance shuts down MySQL.

When `group_replication_exit_state_action` is set to `READ_ONLY`, if the member exits the group unintentionally, the instance switches MySQL to super read only mode (by setting the system variable `super_read_only` to `ON`).

**Important**

The specified exit action is not taken if a failure occurs during the local configuration check, or if there is a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the START GROUP_REPLICATION command fails, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server’s configuration file at startup, and then changed to `OFF` after Group Replication has been started successfully.

• `group_replication_flow_control_applier_threshold`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-flow-control-applier-threshold=value</code></td>
</tr>
<tr>

<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>10</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>100</td>
</tr>
</tbody>
</table>

Defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

- `group_replication_flow_control_max_commit_quota`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--group-replication-flow-control-max-commit-quota=value</code></td>
</tr>
<tr>
<td><strong>Introduced</strong></td>
<td>8.0.2</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>group_replication_flow_control_max_commit_quota</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>

<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
Group Replication System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. Cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-flow-control-member-quota-percent=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_flow_control_member_quota_percent</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

Defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- `group_replication_flow_control_min_quota`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-flow-control-min-quota=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_flow_control_min_quota</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>
Controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- **group_replication_flow_control_min_recovery_quota**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-flow-control-min-recovery-quota=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_flow_control_min_recovery_quota</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- **group_replication_flow_control_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-flow-control-mode=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_flow_control_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>QUOTA</td>
</tr>
<tr>
<td>Valid Values</td>
<td>DISABLED, QUOTA</td>
</tr>
</tbody>
</table>

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- **group_replication_flow_control_period**
### Group Replication System Variables

<table>

</tbody>
</table>

Defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.

- `group_replication_flow_control_release_percent`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--group-replication-force-members=value</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>group_replication_force_members</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>

</tr>
</tbody>
</table>
A list of peer addresses as a comma separated list such as `host1:port1,host2:port2`. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked.

You must specify the address or host name and port as they are given in the `group_replication_local_address` option for each member. An IPv6 address must be specified in square brackets. For example:

```
"198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061,example.org:33061"
```

The group communication engine (XCom) checks that the supplied IP addresses are in a valid format, and checks that you have not included any group members that are currently unreachable. Otherwise, the new configuration is not validated, so you must be careful to include only online servers that are reachable members of the group. Any incorrect values or invalid host names in the list could cause the group to be blocked with an invalid configuration.

It is important before forcing a new membership configuration to ensure that the servers to be excluded have been shut down. If they are not, shut them down before proceeding. Group members that are still online can automatically form new configurations, and if this has already taken place, forcing a further new configuration could create an artificial split-brain situation for the group.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

For details of the procedure to follow, see Section 18.4.4, "Network Partitioning".

```sql
• group_replication_group_name
```

The name of the group which this server instance belongs to. Must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log.

```
Important
A unique UUID must be used.
```

```sql
• group_replication_group_seeds
```
### Group Replication System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-group-seeds=value</code></td>
</tr>
<tr>
<td>System Variable</td>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

A list of group members that provide a member which joins the group with the data required for the joining member to gain synchrony with the group. The list consists of a single internal network address or host name for each included seed member, as configured in the seed member’s `group_replication_local_address` system variable (not the seed member's SQL hostname and port). The addresses of the seed members are specified as a comma separated list, such as `host1:port1,host2:port2`. An IPv6 address must be specified in square brackets. For example:

```plaintext
group_replication_group_seeds= "198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061, example.org:33061"
```

Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when starting Group Replication. If the list does not contain any valid member addresses, issuing `START GROUP_REPLICATION` fails.

When a server is joining a replication group, it attempts to connect to the first seed member listed in its `group_replication_group_seeds` system variable. If the connection is refused, the joining member tries to connect to each of the other seed members in the list in order. If the joining member connects to a seed member but does not get added to the replication group as a result (for example, because the seed member does not have the joining member's address in its whitelist and closes the connection), the joining member continues to try the remaining seed members in the list in order.

A joining member must communicate with the seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address whitelisting for Group Replication, the whitelist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and whitelisted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. For more information, see Section 18.5.1, “IP Address Whitelisting”.

</tr>
<tr>
<td>Default Value</td>
<td>AUTOMATIC</td>
</tr>
</tbody>
</table>

Specifies which hosts are permitted to connect to the group. The address that you specify for each group member in group_replication_local_address must be whitelisted on the other servers in the replication group. Note that the value you specify for this variable is not validated until a START GROUP_REPLICATION statement is issued and the Group Communication System (GCS) is available.

By default, this system variable is set to AUTOMATIC, which permits connections from private subnetworks active on the host. The group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the localhost IP address for IPv4 and (from MySQL 8.0.14) IPv6 are used to create the Group Replication whitelist. For a list of the ranges from which addresses are automatically whitelisted, see Section 18.5.1, “IP Address Whitelisting”.

The automatic whitelist of private addresses cannot be used for connections from servers outside the private network. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit whitelist. If you specify any entries for the whitelist, the private and localhost addresses are not added automatically, so if you use any of these, you must specify them explicitly.

As the value of the group_replication_ip_whitelist option, you can specify any combination of the following:

- IPv4 addresses (for example, 198.51.100.44)
- IPv4 addresses with CIDR notation (for example, 192.0.2.21/24)
Group Replication System Variables

- IPv6 addresses, from MySQL 8.0.14 (for example, 2001:db8:85a3:8d3:1319:8a2e:370:7348)
- IPv6 addresses with CIDR notation, from MySQL 8.0.14 (for example, 2001:db8:85a3:8d3::/64)
- Host names (for example, example.org)
- Host names with CIDR notation (for example, www.example.com/24)

Before MySQL 8.0.14, host names could only resolve to IPv4 addresses. From MySQL 8.0.14, host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to whitelist a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

A comma must separate each entry in the whitelist. For example:

"192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,example.org,www.example.com/24"

If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and whitelist an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). For more information, see Section 18.5.1, “IP Address Whitelisting”.

It is possible to configure different whitelists on different group members according to your security requirements, for example, in order to keep different subnets separate. However, this can cause issues when a group is reconfigured. If you do not have a specific security requirement to do otherwise, use the same whitelist on all members of a group. For more details, see Section 18.5.1, “IP Address Whitelisting”.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for whitelist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

**Warning**

Host names are inherently less secure than IP addresses in a whitelist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_local_address`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--group-replication-local-address=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>group_replication_local_address</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
The network address which the member provides for connections from other members, specified as a host:port formatted string. This address must be reachable by all members of the group because it is used by the group communication engine (XCom, a Paxos variant) for TCP communication between remote XCom instances. Communication with the local instance is over an input channel using shared memory.

**Warning**

Do not use this address for communication with the member. This is not the MySQL server SQL protocol host and port.

The address or host name that you specify in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and you can use the same host name or IP address for all members as long as the ports are all different. The recommended port for `group_replication_local_address` is 33061. Note that the value you specify for this variable is not validated until the `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. From MySQL 8.0.14, IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses. An IPv6 address must be specified in square brackets in order to distinguish the port number, for example:

```plaintext
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. For more information on Group Replication support for IPv6 networks and on replication groups with a mix of members using IPv4 and members using IPv6, see Section 18.4.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

For the purpose of IP address whitelisting for Group Replication, the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_whitelist` option on the other servers in the replication group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when this member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and whitelist an alternative address for this member for the required protocol (or a host name that resolves to an address for that protocol). For more information, see Section 18.5.1, “IP Address Whitelisting”.

**group_replication_member_weight**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>

<td>3600</td>
</tr>
<tr>
<td>Maximum Value (&lt;= 8.0.13)</td>
<td>31536000</td>
</tr>
</tbody>
</table>
The period of time in seconds that a Group Replication group member waits after creating a suspicion before expelling from the group the member suspected of having failed. The initial 5-second detection period before a suspicion is created does not count as part of this time. Changing the value of `group_replication_member_expel_timeout` on a group member takes effect immediately for existing as well as future suspicions on that group member. It is not mandatory for all members of a group to have the same setting, but it is recommended in order to avoid unexpected expulsions.

A group member is expelled when another member’s suspicion of it (or its own suspicion of itself) times out. By default, `group_replication_member_expel_timeout` is set to 0, meaning that there is no waiting period and a suspected member is liable for expulsion immediately after the 5-second detection period ends. An additional short period of time might elapse before the expelling mechanism detects and implements the expulsion. If a group member is at an older MySQL Server version that does not support this setting, this is its behavior towards other members or itself.

To avoid unnecessary expulsions on slower networks, or in the case of expected transient network failures or machine slowdowns, you can specify a timeout value greater than zero, up to a maximum of 3600 seconds (1 hour). If a suspect member becomes active again before the suspicion times out, it rejoins the group, applies all the messages that were buffered by the remaining group members, and enters `ONLINE` state. Otherwise, it is liable for expulsion immediately after the suspicion times out. For alternative mitigation strategies where this system variable is not available, see Section 18.8.2, “Group Replication Limitations”.

The waiting period before expelling a member only applies to members that have previously been active in the group. Non-members that were never active in the group do not get this waiting period and are removed after the initial detection period because they took too long to join.

If any members in a group are currently under suspicion, the group membership cannot be reconfigured (by adding or removing members or electing a new leader). If group membership changes need to be implemented while one or more members are under suspicion, and you want the suspect members to remain in the group, take any actions required to make the members active again, if that is possible. If you cannot make the members active again and you want them to be expelled from the group, you can force the suspicions to time out immediately. Do this by changing the value of `group_replication_member_expel_timeout` on any active members to a value lower than the time that has already elapsed since the suspicions were created. The suspect members then become liable for expulsion immediately.

An expelled member is not allowed to rejoin the group normally. If the expelled member does reconnect to the group and so becomes aware that it was expelled, it follows the action specified by the system variable `group_replication_exit_state_action`. If this system variable is set to `ABORT_SERVER`, which is the default, the expelled member shuts itself down. If it is set to `READ_ONLY`, the expelled member remains online but switches itself to super read only mode.

- `group_replication_poll_spin_loops`

<table>

Configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0 there is no limit to the size of transactions the group accepts. From MySQL 8.0, the default setting for this system variable is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. For further mitigation strategies, see Section 18.8.2, “Group Replication Limitations”.

Configures how long members that suffer a network partition and cannot connect to the majority wait before leaving the group.

In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits
for the specified time for a network reconnection. Any transactions processed by the minority group are blocked until Group Replication is stopped using `STOP GROUP REPLICATION` on the members of the minority. Note that `group_replication_unreachable_majority_timeout` has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

By default, this system variable is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If configured to a number of seconds, members wait for this amount of time after losing contact with the majority of members before leaving the group. When the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the `ERROR` state. These servers then follow the action specified by the system variable `group_replication_exit_state_action`, which can be to set themselves to super read only mode or shut down MySQL.

**Warning**

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter `ERROR` state.

---

**Group Replication Status Variable**

This section describes the status variables which provide information about Group Replication. The variable has the following meaning:

- `group_replication_primary_member`

  Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

**Warning**

The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

See Section 18.4.1.3, “Finding the Primary”.

---

**18.8 Requirements and Limitations**

This section lists and explains the requirements and limitations of Group Replication.

**18.8.1 Group Replication Requirements**

Server instances that you want to use for Group Replication must satisfy the following requirements.

**Infrastructure**

- **InnoDB Storage Engine.** Data must be stored in the InnoDB transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, InnoDB provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication.

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as
a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified.

- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stability of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

From MySQL 8.0.14, you can use an IPv4 or IPv6 network infrastructure, or a mix of the two, for TCP communication between remote Group Replication servers. There is also nothing preventing Group Replication from operating over a virtual private network (VPN).

Also from MySQL 8.0.14, where Group Replication server instances are co-located and share a local group communication engine (XCom) instance, a dedicated input channel with lower overhead is used for communication where possible instead of the TCP socket. For certain Group Replication tasks that require communication between remote XCom instances, such as joining a group, the TCP network is still used, so network performance influences the group's performance.

### Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be on for it to operate. This option is enabled by default. See Section 5.4.4, “The Binary Log”.

- **Slave Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs form participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself. This option is enabled by default.

- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See Section 17.2.1, “Replication Formats”.

- **Global Transaction Identifiers On.** Set `--gtid-mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See Section 17.1.3, “Replication with Global Transaction Identifiers”.

- **Replication Information Repositories.** Set `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE`. The replication applier needs to have the master information and relay log metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. From MySQL 8.0.2, these options are set to `TABLE` by default, and from MySQL 8.0.3, the `FILE` setting is deprecated. See Section 17.2.4.2, “Slave Status Logs”.

- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write
set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts. This option is enabled by default.

- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded slaves, enabling transactions to be applied in parallel. A nonzero value for `slave_parallel_workers` enables the multithreaded applier on the member, and up to 1024 parallel applier threads can be specified. Setting `slave_preserve_commit_order=1` ensures that the final commit of parallel transactions is in the same order as the original transactions, as required for Group Replication, which relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transaction in the same order. Finally, the setting `slave_parallel_type=LOGICAL_CLOCK`, which specifies the policy used to decide which transactions are allowed to execute in parallel on the slave, is required with `slave_preserve_commit_order=1`. Setting `slave_parallel_workers=0` disables parallel execution and gives the slave a single applier thread and no coordinator thread. With that setting, the `slave_parallel_type` and `slave_preserve_commit_order` options have no effect and are ignored.

### 18.8.2 Group Replication Limitations

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

- **Replcation Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.

- **Gap Locks.** The certification process does not take into account gap locks, as information about gap locks is not available outside of InnoDB. See Gap Locks for more information.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”) or named locks (see `GET_LOCK()`).

- **SERIALIZABLE Isolation Level.** `SERIALIZABLE` isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to `SERIALIZABLE` configures Group Replication to refuse to commit the transaction.

- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
• **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined `CASCADING foreign key constraints`. This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

• **Very Large Transactions.** If an individual transaction results in GTID contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

  • Where possible, try and limit the size of your transactions. For example, split up files used with `LOAD DATA` into smaller chunks.

  • Use the system variable `group_replication_transaction_size_limit` to specify a maximum transaction size that the group will accept. Transactions above this size are rolled back and are not sent to the group. In MySQL 8.0, this system variable defaults to a maximum transaction size of 150000000 bytes (approximately 143 MB). Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.

  • From MySQL 8.0.13, you can use the system variable `group_replication_member_expel_timeout` to allow additional time before a member under suspicion of having failed is expelled. You can allow up to an hour after the initial 5-second detection period before a suspect member is expelled from the group.

• **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, `SELECT .. FOR UPDATE` statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.

• **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

• **Encrypted Connections.** Support for the TLSv1.3 protocol is available in MySQL Server as of MySQL 8.0.16, and requires compiling MySQL using OpenSSL 1.1.1 or higher. Group Replication does not currently support TLSv1.3, and if the server was compiled with this support, it is explicitly disabled in the group communication engine.

### 18.9 Frequently Asked Questions

This section provides answers to frequently asked questions.
What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused.

How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to create a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the `CHANGE MASTER TO` statement.

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.
Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member must be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then Section 18.10.7.2, “Message Compression” can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 2 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an
How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port, configured by `group_replication_local_address`, for `mysqld` so that it can bind to it and listen there. To see which ports MySQL is currently allowed to use, issue `semanage port -l | grep mysqld`. Assuming the port configured is 33061, add the necessary port to those permitted by SELinux by issuing `semanage port -a -t mysqld_port_t -p tcp 33061`.

How do I use Group Replication with `iptables`?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in master to slave replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See Section 17.2.4.1, “The Slave Relay Log” for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses 203.0.113.1 and 198.51.100.179. In such a situation you could use 203.0.113.1:33061 for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use 198.51.100.179 for `hostname` and 3306 for the `port`. Client SQL applications would then connect to the member at 198.51.100.179:3306. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, the Group Replication recovery procedure is based on asynchronous replication which uses the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the new member.
How do I find the primary?

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

Important

The assigned value is used directly and is not affected by the `--skip-name-resolve` option.

To configure `MEMBER_PORT` on a server, specify it using the `--report-port` option.

How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See Section 18.4.1.3, “Finding the Primary”

18.10 Group Replication Technical Details

This section provides more technical details about MySQL Group Replication.

18.10.1 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.
The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group.
The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine (XCom). The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see Section 18.1, “Group Replication Background”). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

18.10.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at Section 18.1.3.2, “Group Membership” powers all of this.

18.10.3 Data Manipulation Statements

As there are no primary servers (masters) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any a priori coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

18.10.4 Data Definition Statements

In a Group Replication topology, care needs to be taken when executing data definition statements, also commonly known as data definition language (DDL).

MySQL 8.0 introduces support for atomic Data Definition Language (DDL) statements, where the complete DDL statement is either committed or rolled back as a single atomic transaction. However, DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a COMMIT before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as START TRANSACTION ... COMMIT, or combined with other statements within the same transaction.
Distributed Recovery

Group Replication is based on an optimistic replication paradigm, where statements are optimistically executed and rolled back later if necessary. Each server executes and commits without securing group agreement first. Therefore, more care needs to be taken when replicating DDL statements in multi-primary mode. If you make schema changes (using DDL) and changes to the data that an object contains (using DML) for the same object, the changes need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so can result in data inconsistency when operations are interrupted or only partially completed. If the group is deployed in single-primary mode this issue does not occur, because all changes are performed through the same server, the primary.

For details on atomic DDL support in MySQL 8.0, and the resulting changes in behavior for the replication of certain statements, see Section 13.1.1, "Atomic Data Definition Statement Support".

18.10.5 Distributed Recovery

This section describes the process through which a member joining a group catches up with the remaining servers in the group, called distributed recovery.

18.10.5.1 Distributed Recovery Basics

This section is a high level summary. The following sections provide additional detail, by describing the phases of the procedure in more detail.

Group Replication distributed recovery can be summarized as the process through which a server gets missing transactions from the group so that it can then join the group having processed the same set of transactions as the other group members. During distributed recovery, the server joining the group buffers any transactions and membership events that happen while the server joining the group is receiving the transactions required from the group. Once the server joining the group has received all of the group’s transactions, it applies the transactions that were buffered during the recovery process. At the end of this process the server then joins the group as an online member.

Phase 1

In the first phase, the server joining the group selects one of the online servers on the group to be the donor of the state that it is missing. The donor is responsible for providing the server joining the group all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between the donor and the server joining the group, see Section 17.2.3, “Replication Channels”. Through this replication channel, the donor’s binary logs are replicated until the point that the view change happened when the server joining the group became part of the group. The server joining the group applies the donor's binary logs as it receives them.

While the binary log is being replicated, the server joining the group also caches every transaction that is exchanged within the group. In other words it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the server joining the group then starts phase two: the catch up.

Phase 2

In this phase, the server joining the group proceeds to the execution of the cached transactions. When the number of transactions queued for execution finally reaches zero, the member is declared online.

Resilience

The recovery procedure withstands donor failures while the server joining the group is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the server joining the group fails over
to a new donor and resumes from that one. When that happens the server joining the group closes the
connection to the failed server joining the group explicitly and opens a connection to a new donor. This
happens automatically.

### 18.10.5.2 Recovering From a Point-in-time

To synchronize the server joining the group with the donor up to a specific point in time, the server joining
the group and donor make use of the MySQL Global Transaction Identifiers (GTIDs) mechanism. See
Section 17.1.3, “Replication with Global Transaction Identifiers”. However, GTIDs only provide a means
to realize which transactions the server joining the group is missing, they do not help marking a specific
point in time to which the server joining the group must catch up, nor do they help conveying certification
information. This is the job of binary log view markers, which mark view changes in the binary log stream,
and also contain additional metadata information, provisioning the server joining the group with missing
certification related data.

#### View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view
change are.

A view corresponds to a group of members participating actively in the current configuration, in other words
at a specific point in time. They are correct and online in the system.

A view change occurs when a modification to the group configuration happens, such as a member joining
or leaving. Any group membership change results in an independent view change communicated to all
members at the same logical point in time.

A view identifier uniquely identifies a view. It is generated whenever a view change happens.

At the group communication layer, view changes with their associated view ids are then boundaries
between the data exchanged before and after a member joins. This concept is implemented through a new
binary log event: the "view change log event". The view id thus becomes a marker as well for transactions
transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: (i) one that is randomly generated and (ii) a monotonically
increasing integer. The first part is generated when the group is created, and remains unchanged while
there is at least one member in the group. The second part is incremented every time a view change
happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark
group changes whenever a member joins or leaves but also whenever all members leave the group and no
information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers
could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary
log data markers that recovery depends on. To summarize, the first part identifies whenever the group was
started from the beginning and the incremental part when the group changed from that point on.

### 18.10.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a
binary log event and written to the log. The following steps are taken:

#### Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little
behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed
and replicated database.
Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the server joining the group selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.
Figure 18.11 A Member Joins

State Transfer: Catching Up

Once the server joining the group has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.
As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.
When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.
Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the server joining the group is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

**Warning**

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

**18.10.6 Observability**

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group
Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see Section 18.3, “Monitoring Group Replication”.

18.10.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your group.

18.10.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

18.10.7.2 Message Compression

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load.

Table 18.5 LZ4 Compression Ratios for Different Binary Log Formats

<table>
<thead>
<tr>
<th>Workload</th>
<th>Ratio for ROW</th>
<th>Ratio for STMT</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqlslapd</td>
<td>4.5</td>
<td>4.1</td>
</tr>
<tr>
<td>sysbench</td>
<td>3.4</td>
<td>2.9</td>
</tr>
</tbody>
</table>

The TCP peer-to-peer nature of the interconnections between N participants on the group makes the sender send the same amount of data N times. Furthermore, binary logs are likely to exhibit a high compression ratio (see table above). This makes compression a compelling feature for workloads that contain large transaction.
Figure 18.15 Compression Support

Compression happens at the group communication engine level, before the data is handed over to the group communication thread, so it happens within the context of the mysql user session thread. Transaction payloads may be compressed before being sent out to the group and decompressed when received. Compression is conditional and depends on a configured threshold. By default compression is enabled.

In addition, there is no requirement that all servers in the group have compression enabled to be able to work together. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer.

The compression algorithm used is LZ4. Compression is enabled by default with threshold of 1000000 bytes. The compression threshold, in bytes, may be set to something larger than default. In that case, only transactions that have a payload larger than the threshold are compressed. Below is an example of how to set a compression threshold.

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold= 2097152;
START GROUP_REPLICATION;
```
This sets the compression threshold to 2MB. If a transaction generates a replication message with a payload larger than 2MB, for example a binary log transaction entry larger than 2MB, then it is compressed. To disable compression set threshold to 0.

### 18.10.7.3 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the certification queue; (ii) and on the binary log applier queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

### Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
• the total number of transactions certified;
• the total number of remote transactions applied in the member;
• the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

**Group Replication Throttling**

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota will be enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.
Chapter 19 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at https://dev.mysql.com/doc/mysql-shell/en/.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables you to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. For more information, see Chapter 20, *Using MySQL as a Document Store*. For documentation on the concepts and usage of X DevAPI, see X DevAPI User Guide.

- The AdminAPI enables you to work with InnoDB cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. See Chapter 21, *InnoDB Cluster*.

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as "using NoSQL". If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Traditionally, relational databases such as MySQL have usually required a schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. For example, when you create documents describing products, you do not need to know and define all possible attributes of any products before storing and operating with the documents. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

To use MySQL as a document store, you use the following server features:

• X Plugin enables MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. X Plugin is enabled by default in MySQL Server as of MySQL 8.0. For instructions to verify X Plugin installation and to configure and monitor X Plugin, see Section 20.5, "X Plugin".

• X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer. Clients compatible with X Protocol include MySQL Shell and MySQL 8.0 Connectors.

• Clients that communicate with a MySQL Server using X Protocol can use X DevAPI to develop applications. X DevAPI offers a modern programming interface with a simple yet powerful design which
provides support for established industry standard concepts. This chapter explains how to get started using either the JavaScript or Python implementation of X DevAPI in MySQL Shell as a client. See X DevAPI User Guide for in-depth tutorials on using X DevAPI.

20.1 Interfaces to a MySQL Document Store

To work with MySQL as a document store, you use dedicated components and a choice of clients that support communicating with the MySQL server to develop document based applications.

• The following MySQL products support X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store:
  • MySQL Shell (which provides implementations of X DevAPI in JavaScript and Python)
  • Connector/C++
  • Connector/J
  • Connector/Node.js
  • Connector/NET
  • Connector/Python
  • MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use MySQL Shell to prototype applications, execute queries and update data. Installing MySQL Shell has instructions to download and install MySQL Shell.
  • The quick-start guides (tutorials) in this chapter help you to get started using MySQL Shell with MySQL as a document store.
    The quick-start guide for Python is here: Section 20.4, “Python Quick-Start Guide: MySQL Shell for Document Store”.
  • The MySQL Shell User Guide at MySQL Shell 8.0 (part of MySQL 8.0) provides detailed information about configuring and using MySQL Shell.

20.2 Document Store Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

JSON Document

A JSON document is a data structure composed of key-value pairs and is the fundamental structure for using MySQL as document store. For example, the world_x schema (installed later in this chapter) contains this document:

```json
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
```
This document shows that the values of keys can be simple data types, such as integers or strings, but can also contain other documents, arrays, and lists of documents. For example, the `geography` key's value consists of multiple key-value pairs. A JSON document is represented internally using the MySQL binary JSON object, through the `JSON` MySQL datatype.

The most important differences between a document and the tables known from traditional relational databases are that the structure of a document does not have to be defined in advance, and a collection can contain multiple documents with different structures. Relational tables on the other hand require that their structure be defined, and all rows in the table must contain the same columns.

### Collection

A collection is a container that is used to store JSON documents in a MySQL database. Applications usually run operations against a collection of documents, for example to find a specific document.

### CRUD Operations

The four basic operations that can be issued against a collection are Create, Read, Update and Delete (CRUD). In terms of MySQL this means:

- Create a new document (insertion or addition)
- Read one or more documents (queries)
- Update one or more documents
- Delete one or more documents

### 20.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

### Related Information

- [MySQL Shell 8.0 (part of MySQL 8.0)](https://dev.mysql.com/doc/mysql-shell/en/) provides more in-depth information about MySQL Shell.
20.3.1 Import Database Sample

The world_x database sample contains one JSON collection and a set of three relational tables:

- Collection
  - countryinfo: Information about countries in the world.

- Tables
  - country: Minimal information about countries of the world.
  - city: Information about some of the cities in those countries.
  - countrylanguage: Languages spoken in each country.

Requirements

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. See Installing MySQL Shell. Start MySQL before you load the example world_x database for this guide.

Download and Import world_x Database

To prepare the world_x database sample, follow these steps:

1. Download world_x-db.zip.
2. Extract the installation archive to a temporary location such as /tmp/. Unpacking the archive results in a single file named world_x.sql.
3. Import the world_x.sql file to your database. You can either:
   - Start MySQL Shell in SQL mode and import the file by issuing:
     ```
     mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
     Enter password: ****
     ```
   - Set MySQL Shell to SQL mode while it is running and source the schema file while MySQL Shell is running by issuing:
     ```
     \source /tmp/world_x-db/world_x.sql
     Switching to SQL mode... Commands end with ;
     \source /tmp/world_x-db/world_x.sql
     ```
     Replace /tmp/ with the path to the world_x.sql file on your system. Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Related Information

- MySQL Shell Sessions explains session types.
• See Chapter 2, Installing and Upgrading MySQL for general installation assistance.

### 20.3.2 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the MySQL server instance.

#### Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using X Protocol. You need to know the address of the MySQL server instance you plan to connect to.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh name@host/world_x
```

Alternatively, if MySQL Shell is already running use the \ connect command by issuing:

```
\connect name@host/world_x
```

You need to specify the address of your MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `name` represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.3.1, “Import Database Sample”.

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is JavaScript.

```
mysql-js>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. For more information, see MySQL Shell Connections.

MySQL Shell supports input-line editing as follows:

- `left-arrow` and `right-arrow` keys move horizontally within the current input line.
- `up-arrow` and `down-arrow` keys move up and down through the set of previously entered lines.
- `Backspace` deletes the character before the cursor and typing new characters enters them at the cursor position.
- `Enter` sends the current input line to the server.

#### Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.
Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you can create, list, and drop.

The examples in this section use the countryinfo collection in the world_x database. For instructions on setting up the world_x database sample, see Section 20.3.1, “Import Database Sample”.

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:

  ```
  {field1: "value", field2 : 10, "field 3": null}
  ```

  An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for JavaScript:

  ```
  [{Name: "Aruba", _id: "ABW"}, {Name: "Angola", _id: "AGO"}]
  ```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
• boolean (False and True)
• null
• arrays of more JSON values
• nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

• Basic objects include:

<table>
<thead>
<tr>
<th>Object form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db</code></td>
<td><code>db</code> is a global variable assigned to the current active schema. When you</td>
</tr>
<tr>
<td></td>
<td>want to run operations against the schema, for example to retrieve a</td>
</tr>
<tr>
<td></td>
<td>collection, you use methods available for the <code>db</code> variable.</td>
</tr>
<tr>
<td><code>db.getCollections()</code></td>
<td><code>db.getCollections()</code> holds a list of collections in the schema. Use the</td>
</tr>
<tr>
<td></td>
<td>list to get references to collection objects, iterate over them, and so</td>
</tr>
<tr>
<td></td>
<td>on.</td>
</tr>
</tbody>
</table>

• Basic operations scoped by collections include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.add()</code></td>
<td>The <code>add()</code> method inserts one document or a list of documents into the</td>
</tr>
<tr>
<td></td>
<td>named collection.</td>
</tr>
<tr>
<td><code>db.name.find()</code></td>
<td>The <code>find()</code> method returns some or all documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.modify()</code></td>
<td>The <code>modify()</code> method updates documents in the named collection.</td>
</tr>
<tr>
<td><code>db.name.remove()</code></td>
<td>The <code>remove()</code> method deletes one document or a list of documents from the</td>
</tr>
<tr>
<td></td>
<td>named collection.</td>
</tr>
</tbody>
</table>

Related Information

• See Working with Collections for a general overview.
• CRUD EBNF Definitions provides a complete list of operations.

20.3.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.
Documents and Collections

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```plaintext
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```plaintext
mysql-js> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` database.

```plaintext
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```plaintext
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `db` object's `getCollections()` method. Collections returned by the server you are currently connected to appear between brackets.

```plaintext
mysql-js> db.getCollections()
{
    <Collection:countryinfo>,
    <Collection:flags>
}
```

Drop a Collection

To drop an existing collection from a database, use the `db` object's `dropCollection()` method. For example, to drop the `flags` collection from the `world_x` database, type:

```plaintext
mysql-js> db.dropCollection("flags")
```

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database.

Related Information

- See Collection Objects for more examples.

20.3.3.2 Add Documents

Use the `add()` method to insert one document or a list of documents into an existing collection using MySQL Shell. All examples in this section use the `countryinfo` collection, which is provided in the `world_x` schema.

Add a Document

Insert the following document into the `countryinfo` collection. As this is multi-line content, press `Enter` twice to insert the document.
The method returns the status of the operation.

Each document requires an identifier field called _id. The value of the _id field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an _id value. A MySQL server at 8.0.11 or higher sets an _id value if the document does not contain the _id field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an _id value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 Document is missing a required field.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

20.3.3.3 Find Documents

You can use the find() method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the find() method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: OR (| |), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, !-, <>, >=, <=, |, &&, |, <>, >=, <=, |, and %.

Find All Documents in a Collection

To return all documents in a collection, use the find() method without specifying search conditions. For example, the following operation returns all documents in the countryinfo collection.

```sql
mysql-j> db.countryinfo.find()
```
The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

| Empty set (0.00 sec) |

### Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 12, Functions and Operators. You must enclose all expressions in quotes.

All examples in this section use the countryinfo collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-js> db.countryinfo.find("Name = 'Australia'")
[   {   "GNP": 351182,
       "IndepYear": 1901,
       "Name": "Australia",
       "_id": "AUS",
       "demographics": {   "LifeExpectancy": 79.80000305175781,
                            "Population": 18886000
                        },
       "geography": {   "Continent": "Oceania",
                        "Region": "Australia and New Zealand",
                        "SurfaceArea": 7741220
                    },
       "government": {   "GovernmentForm": "Constitutional Monarchy, Federation",
                          "HeadOfState": "Elisabeth II"
                   }
   }
]
```

The following example searches for all countries that have a GNP higher than $500 billion. The countryinfo collection measures GNP in units of million.

```
mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```
The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```javascript
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

```javascript
mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```javascript
mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
[  
  {  
    "GNP": 1161755,
    "IndepYear": 1861,
    "Name": "Italy",
    "_id": "ITA",
    "demographics": {
      "LifeExpectancy": 79,
      "Population": 57680000
    },
    "geography": {
      "Continent": "Europe",
      "Region": "Southern Europe",
      "SurfaceArea": 301316
    },
    "government": {
      "GovernmentForm": "Republic",
      "HeadOfState": "Carlo Azeglio Ciampi"
    }
  }  
]
1 document in set (0.01 sec)
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.
Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```javascript
mysql-js> var myFind = db.countryinfo.find("Name = :country")
mysql-js> myFind.bind('country', 'France')
{
   "GNP": 1424285,
   "IndepYear": 843,
   "Name": "France",
   "_id": "FRA",
   "demographics": {
     "LifeExpectancy": 78.80000305175781,
     "Population": 59225700
   },
   "geography": {
     "Continent": "Europe",
     "Region": "Western Europe",
     "SurfaceArea": 551500
   },
   "government": {
     "GovernmentForm": "Republic",
     "HeadOfState": "Jacques Chirac"
   }
}
1 document in set (0.0028 sec)

mysql-js> myFind.bind('country', 'Germany')
{
   "GNP": 2133367,
   "IndepYear": 1955,
   "Name": "Germany",
   "_id": "DEU",
   "demographics": {
     "LifeExpectancy": 77.4000015258789,
     "Population": 82164700
   },
   "geography": {
     "Continent": "Europe",
     "Region": "Western Europe",
     "SurfaceArea": 357022
   },
   "government": {
     "GovernmentForm": "Federal Republic",
     "HeadOfState": "Johannes Rau"
   }
}
1 document in set (0.0026 sec)
```

**Project Results**

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the countryinfo collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.
Documents and Collections

mysql-js> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
{
"GNP": 8510700,
"Name": "United States"
}
]
1 document in set (0.00 sec)

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new
field values—with an expression that describes the document to return. For example, alter the names of
the fields with the following expression to return only two documents.
mysql-js> db.countryinfo.find().
fields(mysqlx.expr('{"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).
limit(2)
[
{
"GNPPerCapita": 8038.834951456311,
"Name": "ARUBA"
},
{
"GNPPerCapita": 263.0281690140845,
"Name": "AFGHANISTAN"
}
]
2 documents in set (0.00 sec)

Limit, Sort, and Skip Results
You can apply the limit(), sort(), and skip() methods to manage the number and order of
documents returned by the find() method.
To specify the number of documents included in a result set, append the limit() method with a value to
the find() method. The following query returns the first five documents in the countryinfo collection.
mysql-js> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)

To specify an order for the results, append the sort() method to the find() method. Pass to the
sort() method a list of one or more fields to sort by and, optionally, the descending (desc) or ascending
(asc) attribute as appropriate. Ascending order is the default order type.
For example, the following query sorts all documents by the IndepYear field and then returns the first eight
documents in descending order.
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)

By default, the limit() method starts from the first document in the collection. You can use the skip()
method to change the starting document. For example, to ignore the first document and return the next
eight documents matching the condition, pass to the skip() method a value of 1.
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)

3359


Related Information

- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See CollectionFindFunction for the full syntax definition.

### 20.3.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

#### Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```javascript
mysql-javascript> db.countryinfo.modify("_id = 'SEA'").set("demographics", {LifeExpectancy: 78, Population: 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```javascript
mysql-javascript> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```javascript
mysql-javascript> db.countryinfo.find("Name = 'Sealand'")
[ {
    "IndepYear": 1967,
    "Name": "Sealand",
    "_id": "SEA",
    "demographics": {
        "LifeExpectancy": 78,
        "Population": 28
    },
    "geography": {
        "Continent": "Europe",
        "Region": "British Islands",
        "SurfaceArea": 193
    },
    "government": {
        "GovernmentForm": "Monarchy",
        "HeadOfState": "Michael Bates"
    }
}
]```
Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

```
Caution
Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.
```

```
mysql-js> db.countryinfo.modify("true").set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the `Airports` field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$Airports` in the following example represents the `Airports` field of the current document.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use `db.countryinfo.find("Name = 'France'")` to see the change.

To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```

Related Information

- The MySQL Reference Manual provides instructions to help you search for and modify JSON values.
- See CollectionModifyFunction for the full syntax definition.

20.3.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the `countryinfo` collection. In this example, one document matches the condition.
Remove the First Document

To remove the first document in the countryinfo collection, use the `limit()` method with a value of 1.

```
mysql-js> db.countryinfo.remove("true").limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the countryinfo collection by country name.

```
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying any search condition.

⚠️ Caution

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See `CollectionRemoveFunction` for the full syntax definition.
- See `Section 20.3.1, “Import Database Sample”` for instructions to recreate the `world_x` database.

20.3.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `createIndex()` method an index name. Duplicate index names are prohibited.
In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `false`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.createIndex("pop").field("demographics.Population", "INTEGER", false).execute()
Query OK (0.04 sec)
```

### Add a Unique Index

To create a unique index, pass to the `createIndex()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country "Name" is another common field in the countryinfo collection to index. In the following example, "Text (40)" represents the number of characters to index and `true` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.createIndex("name", mysqlx.IndexType.UNIQUE).field("Name", "TEXT(40)", true).execute()
Query OK (0.04 sec)
```

### Drop an Index

To drop an index, pass to the `dropIndex()` method the name of the index to drop. For example, you can drop the “pop” index as follows:

```
mysql-js> db.countryinfo.dropIndex("pop").execute()
Query OK (0.58 sec)
```

### Related Information

- See [Collection Index Management Functions](#) for the full syntax definition.

### 20.3.4 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` database.

#### Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
```

#### Show All Tables

To display all relational tables in the `world_x` database, use the `getTables()` method on the schema object.
Basic Table Operations

Basic operations scoped by tables include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.insert()</code></td>
<td>The <code>insert()</code> method inserts one or more records into the named table.</td>
</tr>
<tr>
<td><code>db.name.select()</code></td>
<td>The <code>select()</code> method returns some or all records in the named table.</td>
</tr>
<tr>
<td><code>db.name.update()</code></td>
<td>The <code>update()</code> method updates records in the named table.</td>
</tr>
<tr>
<td><code>db.name.delete()</code></td>
<td>The <code>delete()</code> method deletes one or more records from the named table.</td>
</tr>
</tbody>
</table>

Related Information

- See Working with Relational Tables for a general overview.
- CRUD EBNF Definitions provides a complete list of operations.
- See Section 20.3.1, “Import Database Sample” for instructions on setting up the `world_x` database sample.

20.3.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` database, insert the following record and press Enter twice.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode", "District", "Info").
          values(null, "Olympia", "USA", "Washington", '{"Population": 5000}')
Query OK, 1 item affected (0.01 sec)
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").
          values(null, "Little Falls", "USA").values(null, "Happy Valley", "USA")
Query OK, 2 item affected (0.03 sec)
```
When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

**Related Information**

- See `TableInsertFunction` for the full syntax definition.

### 20.3.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: _OR_ (`| |`), _AND_ (`&&`), _XOR_, _IS_, _NOT_, _BETWEEN_, _IN_, _LIKE_, `!=`, `< >`, `>=`, `< =`, `|`, `<<`, `>>`, `+`, `*`, `/`, `~`, and `%.

**Select All Records**

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

```
mysql> db.city.select();
+------+------------+-------------+------------+-------------------------+
| ID   | Name       | CountryCode | District   | Info                    |
+------+------------+-------------+------------+-------------------------+
| 1    | Kabul      | AFG         | Kabol      |{"Population": 1780000} |
| 2    | Qandahar   | AFG         | Qandahar   |{"Population": 237500}  |
| 3    | Herat      | AFG         | Herat      |{"Population": 186800}  |
| ...  | ...        | ...         | ...        | ...                     |
| 4079 | Rafah      | PSE         | Rafah      |{"Population": 92020}   |
+------+------- ----+-------------+------------+-------------------------+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

**Filter Searches**

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql> db.city.select(["Name", "CountryCode"])
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Kabul             | AFG         |
| Qandahar          | AFG         |
| Herat             | AFG         |
| Mazar-e-Sharif    | AFG         |
| Amsterdam         | NLD         |
```

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.
To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```javascript
mysql-js> db.city.select(["Name", "CountryCode"])
    .where("Name like 'Z%'")
```

```
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIH</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhezqazghan</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
</tbody>
</table>
```

...                 ...

59 rows in set (0.00 sec)

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%'" as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```javascript
mysql-js> db.city.select(["Name", "CountryCode"])
    .where("Name like :name").bind("name", "Z%")
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

**Project Results**

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```javascript
mysql-js> db.city.select(["Name", "CountryCode"])
    .where("Name like 'Z%' and CountryCode = 'CHN'")
```

```bash
+----------------+-------------+------------------
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
</table>
```

4082 rows in set (0.00 sec)
<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zaozhuang</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zhangjiagang</td>
<td>CHN</td>
</tr>
</tbody>
</table>

22 rows in set (0.01 sec)

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of **AND** and **OR** operators.

```javascript
mysql-js> db.city.select(['Name', 'CountryCode']).
  .where('Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')')
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

29 rows in set (0.01 sec)

**Limit, Order, and Offset Results**

You can apply the `limit()`, `orderBy()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```javascript
mysql-js> db.country.select(['Code', 'Name']).limit(5)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABW</td>
<td>Aruba</td>
</tr>
<tr>
<td>AFG</td>
<td>Afghanistan</td>
</tr>
<tr>
<td>AGO</td>
<td>Angola</td>
</tr>
<tr>
<td>AIA</td>
<td>Anguilla</td>
</tr>
<tr>
<td>ALB</td>
<td>Albania</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the `Name` column and then returns the first three records in descending order.

```javascript
mysql-js> db.country.select(['Code', 'Name']).orderBy(['Name desc']).limit(3)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
</table>

3367
By default, the limit() method starts from the first record in the table. You can use the offset() method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the offset() method a value of 1.

```sql
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
```

### Related Information
- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See TableSelectFunction for the full syntax definition.

### 20.3.4.3 Update Tables

You can use the update() method to modify one or more records in a table. The update() method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the set() method the new city name. Then, pass to the where() method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```sql
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the select() method to verify the change.

```sql
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
```

### Related Information
- See TableUpdateFunction for the full syntax definition.

### 20.3.4.4 Delete Tables

You can use the delete() method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the delete() method to filter and order the records to be deleted.
Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-js> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-js> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Drop a Table

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the citytest table from the `world_x` database, type:

```
mysql-js> session.dropCollection("world_x", "citytest")
Query OK (0.04 sec)
```

Related Information

- See `TableDeleteFunction` for the full syntax definition.
- See Section 20.3.1, “Import Database Sample” for instructions to recreate the `world_x` database.

20.3.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native JSON data type.

Examples in this section use the city table in the `world_x` database.

City Table Description

The city table has five columns (or fields).
Python Quick-Start Guide: MySQL Shell for Document Store

| CountryCode
| char(3)
| NO
|
|
|
|
| District
| char(20)
| NO
|
|
|
|
| Info
| json
| YES
|
| null
|
|
+---------------+------------+-------+-------+---------+------------------+

Insert a Record
To insert a document into the column of a table, pass to the values() method a well-formed JSON
document in the correct order. In the following example, a document is passed as the final value to be
inserted into the Info column.
mysql-js> db.city.insert().
values(null, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)

Select a Record
You can issue a query with a search condition that evaluates document values in the expression.
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).
bind('country', 'USA')
+------+----------------+-------------+----------------+-----------------------------+
| ID
| Name
| CountryCode | District
| Info
|
+------+----------------+-------------+----------------+-----------------------------+
| 3793 | New York
| USA
| New York
| {"Population": 8008278}
|
| 3794 | Los Angeles
| USA
| California
| {"Population": 3694820}
|
| 3795 | Chicago
| USA
| Illinois
| {"Population": 2896016}
|
| 3796 | Houston
| USA
| Texas
| {"Population": 1953631}
|
| 3797 | Philadelphia
| USA
| Pennsylvania
| {"Population": 1517550}
|
| 3798 | Phoenix
| USA
| Arizona
| {"Population": 1321045}
|
| 3799 | San Diego
| USA
| California
| {"Population": 1223400}
|
| 3800 | Dallas
| USA
| Texas
| {"Population": 1188580}
|
| 3801 | San Antonio
| USA
| Texas
| {"Population": 1144646}
|
+------+----------------+-------------+----------------+-----------------------------+
9 rows in set (0.01 sec)

Related Information

20.4 Python Quick-Start Guide: MySQL Shell for Document Store
This quick-start guide provides instructions to begin prototyping document store applications interactively
with MySQL Shell. The guide includes the following topics:
• Introduction to MySQL functionality, MySQL Shell, and the world_x database sample.
• Operations to manage collections and documents.
• Operations to manage relational tables.
• Operations that apply to documents within tables.

Related Information
• MySQL Shell 8.0 (part of MySQL 8.0) provides more in-depth information about MySQL Shell.

3370


20.4.1 Import Database Sample

The world_x database sample contains one JSON collection and a set of three relational tables:

- Collection
  - countryinfo: Information about countries in the world.

- Tables
  - country: Minimal information about countries of the world.
  - city: Information about some of the cities in those countries.
  - countrylanguage: Languages spoken in each country.

Requirements

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. See Installing MySQL Shell. Start MySQL before you load the example world_x database for this guide.

Download and Import world_x Database

To prepare the world_x database sample, follow these steps:

1. Download world_x-db.zip.
2. Extract the installation archive to a temporary location such as /tmp/. Unpacking the archive results in a single file named world_x.sql.
3. Import the world_x.sql file to your database. You can either:
   - Start MySQL Shell in SQL mode and import the file by issuing:
     ```
     mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
     Enter password: ****
     ```
   - Set MySQL Shell to SQL mode while it is running and source the schema file while MySQL Shell is running by issuing:
     ```
     \source /tmp/world_x-db/world_x.sql
     Switching to SQL mode... Commands end with ;
     \source /tmp/world_x-db/world_x.sql
     ```
     Replace /tmp/ with the path to the world_x.sql file on your system. Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Related Information

- MySQL Shell Sessions explains session types.
20.4.2 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using X Protocol. You need to know the address of the MySQL server instance you plan to connect to.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh name@localhost/world_x --py
```

Alternatively, if MySQL Shell is already running use the \connect command by issuing:

```
\connect name@host/world_x
```

You need to specify the address of your MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `name` represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The `--py` option starts MySQL Shell in Python mode. If you omit `--py`, MySQL Shell starts in JavaScript mode.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.4.1, “Import Database Sample”.

Once MySQL Shell opens, the `mysql-py>` prompt indicates that the active language for this session is Python.

```
mysql-py>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. For more information, see MySQL Shell Connections.

MySQL Shell supports input-line editing as follows:

- `left-arrow` and `right-arrow` keys move horizontally within the current input line.
- `up-arrow` and `down-arrow` keys move up and down through the set of previously entered lines.
- `Backspace` deletes the character before the cursor and typing new characters enters them at the cursor position.
- `Enter` sends the current input line to the server.
Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-py> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
mysql-py> \quit
```

Related Information

- See Interactive Code Execution for an explanation of how interactive code execution works in MySQL Shell.
- See Getting Started with MySQL Shell to learn about session and connection alternatives.
- See Section 4.2.3, “Connecting Using a URI or Key-Value Pairs” to learn about specifying the location of a MySQL server.

20.4.3 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you can create, list, and drop.

The examples in this section use the countryinfo collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.4.1, “Import Database Sample”.

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

```
{"field1": "value", "field2": 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for Python:
MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

**Collections**

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

<table>
<thead>
<tr>
<th>Object form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db</td>
<td><em>db</em> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <em>db</em> variable.</td>
</tr>
<tr>
<td>db.get_collections()</td>
<td><em>db.get_collections()</em> holds a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.</td>
</tr>
</tbody>
</table>

- Basic operations scoped by collections include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.name.add()</td>
<td>The <em>add()</em> method inserts one document or a list of documents into the named collection.</td>
</tr>
<tr>
<td>db.name.find()</td>
<td>The <em>find()</em> method returns some or all documents in the named collection.</td>
</tr>
<tr>
<td>db.name.modify()</td>
<td>The <em>modify()</em> method updates documents in the named collection.</td>
</tr>
<tr>
<td>db.name.remove()</td>
<td>The <em>remove()</em> method deletes one document or a list of documents from the named collection.</td>
</tr>
</tbody>
</table>

**Related Information**

- See [Working with Collections](#) for a general overview.
• **CRUD EBNF Definitions** provides a complete list of operations.

### 20.4.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

#### Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```sql
mysql-py> db
```

If the schema value is not **Schema:world_x**, then set the `db` variable by issuing:

```sql
mysql-py> \use world_x
```

#### Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` database.

```sql
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```sql
<Collection:flags>
```

#### List Collections

To display all collections in the `world_x` database, use the `db` object's `get_collections()` method. Collections returned by the server you are currently connected to appear between brackets.

```sql
mysql-py> db.get_collections()
```

```sql
[<Collection:countryinfo>, <Collection:flags>]
```

#### Drop a Collection

To drop an existing collection from a database, use the `db` object's `drop_collection()` method. For example, to drop the `flags` collection from the `world_x` database, type:

```sql
mysql-py> session.drop_collection("world_x", "flags")
```

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database.

#### Related Information

- See **Collection Objects** for more examples.
20.4.3.2 Add Documents

Use the `add()` method to insert one document or a list of documents into an existing collection using MySQL Shell. All examples in this section use the `countryinfo` collection, which is provided in the `world_x` schema.

Add a Document

Insert the following document into the `countryinfo` collection. As this is multi-line content, press `Enter` twice to insert the document.

```sql
mysql-py> db.countryinfo.add(
{
    GNP: .6,
    IndepYear: 1967,
    Name: "Sealand",
    demographics: {
        LifeExpectancy: 79,
        Population: 27
    },
    geography: {
        Continent: "Europe",
        Region: "British Islands",
        SurfaceArea: 193
    },
    government: {
        GovernmentForm: "Monarchy",
        HeadOfState: "Michael Bates"
    }
}
)
```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 `Document is missing a required field`.

Related Information

- See `CollectionAddFunction` for the full syntax definition.
- See `Understanding Document IDs`.

20.4.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR ( | | ), AND (&&), XOR, IS, NOT, BETWEEN, IN, LIKE, !=, <>, >, >=, <, <=, & , <<, >>, +, -, *, /, ~, and %`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.
The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

Empty set (0.00 sec)

Filter Searches

You can include search conditions with the find() method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 12, Functions and Operators. You must enclose all expressions in quotes.

All examples in this section use the countryinfo collection in the world_x database. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the Name field and a value we know is in a document. The following example returns a single document:
Documents and Collections

The following example searches for all countries that have a GNP higher than $500 billion. The countryinfo collection measures GNP in units of million.

```bash
mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```bash
mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

```bash
mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```bash
mysql-py> db.countryinfo.find("Name = :country").bind("country", "Italy")
[{
"GNP": 1161755,
"IndepYear": 1861,
"Name": "Italy",
"_id": "ITA",
"demographics": {
"LifeExpectancy": 79,
"Population": 57680000
},
"geography": {
"Continent": "Europe",
"Region": "Southern Europe",
```

Note

Seven documents in the countryinfo collection have a population value of zero. Warning messages appear at the end of the output.
Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```javascript
mysql-ja> var myFind = db.countryinfo.find("Name = :country")
mysql-ja> myFind.bind('country', 'France')
[{
  "GNP": 1424285,
  "IndepYear": 843,
  "Name": "France",
  "_id": "FRA",
  "demographics": {
    "LifeExpectancy": 78.80000305175781,
    "Population": 59225700
  },
  "geography": {
    "Continent": "Europe",
    "Region": "Western Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "GovernmentForm": "Republic",
    "HeadOfState": "Jacques Chirac"
  }
}]
1 document in set (0.0028 sec)

mysql-ja> myFind.bind('country', 'Germany')
[{
  "GNP": 2133367,
  "IndepYear": 1955,
  "Name": "Germany",
  "_id": "DEU",
  "demographics": {
    "LifeExpectancy": 77.4000015258789,
    "Population": 82164700
  },
  "geography": {
    "Continent": "Europe",
    "Region": "Western Europe",
    "SurfaceArea": 357022
  }
}]
1 document in set (0.0028 sec)
```
Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the countryinfo collection matching the search conditions.

Use the fields() method to pass the list of fields to return.

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

Limit, Sort, and Skip Results

You can apply the limit(), sort(), and skip() methods to manage the number and order of documents returned by the find() method.

To specify the number of documents included in a result set, append the limit() method with a value to the find() method. The following query returns the first five documents in the countryinfo collection.

To specify an order for the results, append the sort() method to the find() method. Pass to the sort() method a list of one or more fields to sort by and, optionally, the descending (desc) or ascending (asc) attribute as appropriate. Ascending order is the default order type.
For example, the following query sorts all documents by the IndepYear field and then returns the first eight documents in descending order.

```python
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```python
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

**Related Information**

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

### 20.4.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

**Set and Unset Fields**

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```python
mysql-py> db.countryinfo.modify(_id = 'SEA').
    set("demographics", {
      "LifeExpectancy": 78,
      "Population": 28
    })
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```python
mysql-py> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```python
mysql-py> db.countryinfo.find("Name = 'Sealand'")
```
Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the array_append(), array_insert(), or array_delete() methods. The following examples modify the countryinfo collection to enable tracking of international airports.

The first example uses the modify() and set() methods to create a new Airports field in all documents.

```python
mysql-py> db.countryinfo.modify(True).set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the Airports field added, the next example uses the array_append() method to add a new airport to one of the documents. $.Airports in the following example represents the Airports field of the current document.

```python
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use db.countryinfo.find("Name = 'France'") to see the change.

To insert an element at a different position in the array, use the array_insert() method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```python
mysql-py> db.countryinfo.modify("Name = 'France'").array_insert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the array_delete() method the index of the element to be deleted.

```python
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```
Related Information

- The MySQL Reference Manual provides instructions to help you search for and modify JSON values.
- See CollectionModifyFunction for the full syntax definition.

20.4.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the countryinfo collection. In this example, one document matches the condition.

```
mysql-py> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the countryinfo collection, use the `limit()` method with a value of 1.

```
mysql-py> db.countryinfo.remove(True).limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the countryinfo collection by country name.

```
mysql-py> db.countryinfo.remove(True).sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove(True)` method without specifying a search condition.

**Caution**

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See CollectionRemoveFunction for the full syntax definition.
- See Section 20.4.1, “Import Database Sample” for instructions to recreate the `world_x` database.

20.4.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger
the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```javascript
mysql-js> db.countryinfo.find("demographics.Population < 100")
...
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

**Add a Nonunique Index**

To create a nonunique index, pass to the `create_index()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `False`, the field can contain `NULL` values.

```javascript
mysql-js> db.countryinfo.create_index("pop").
Query OK (0.04 sec)
```

**Add a Unique Index**

To create a unique index, pass to the `create_index()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country "Name" is another common field in the countryinfo collection to index. In the following example, "Text(40)" represents the number of characters to index and `True` indicates that the field cannot contain any `NULL` values.

```javascript
mysql-js> db.countryinfo.create_index("name", mysqlx.IndexType.UNIQUE).
field("Name", "TEXT(40)", True).execute()
Query OK (0.04 sec)
```

**Drop an Index**

To drop an index, pass to the `drop_index()` method the name of the index to drop. For example, you can drop the "pop" index as follows:

```javascript
mysql-js> db.countryinfo.drop_index("pop").execute()
Query OK (0.58 sec)
```

**Related Information**

- See [Collection Index Management Functions](#) for the full syntax definition.

**20.4.4 Relational Tables**

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.
In MySQL, each relational table is associated with a particular storage engine. The examples in this section use InnoDB tables in the world_x database.

**Confirm the Schema**

To show the value that is assigned to the schema variable, type `db`.

```bash
mysql-py> db
<Schema:world_x>
```

If the schema value is not the `Schema:world_x` database, then set the `db` variable as follows:

```bash
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

**Show All Tables**

To display all relational tables in the `world_x` database, use the `get_tables()` method on the schema object.

```bash
mysql-py> db.get_tables()
{
    "city": <Table:city>,
    "country": <Table:country>,
    "countrylanguage": <Table:countrylanguage>
}
```

**Basic Table Operations**

Basic operations scoped by tables include:

<table>
<thead>
<tr>
<th>Operation form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.name.insert()</code></td>
<td>The <code>insert()</code> method inserts one or more records into the named table.</td>
</tr>
<tr>
<td><code>db.name.select()</code></td>
<td>The <code>select()</code> method returns some or all records in the named table.</td>
</tr>
<tr>
<td><code>db.name.update()</code></td>
<td>The <code>update()</code> method updates records in the named table.</td>
</tr>
<tr>
<td><code>db.name.delete()</code></td>
<td>The <code>delete()</code> method deletes one or more records from the named table.</td>
</tr>
</tbody>
</table>

**Related Information**

- See [Working with Relational Tables](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.4.1, “Import Database Sample”](#) for instructions on setting up the `world_x` database sample.

**20.4.4.1 Insert Records into Tables**

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.
Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press Enter twice.

```python
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").
values(None, "Olympia", "USA", "Washington", '{"Population": 5000}')
Query OK, 1 item affected (0.01 sec)
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```python
mysql-py> db.city.insert("ID", "Name", "CountryCode").
values(None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
Query OK, 2 item affected (0.03 sec)
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

• See `TableInsertFunction` for the full syntax definition.

20.4.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `|`, `&&`, `| |`, `+`, `*`, `/`, `~`, and `%.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

```python
mysql-py> db.city.select()
+------+------------+-------------+------------+-------------------------+
| ID   | Name       | CountryCode | District   | Info                    |
+------+------------+-------------+------------+-------------------------+
| 1    | Kabul      | AFG         | Kabol      |{"Population": 1780000} |
| 2    | Qandahar   | AFG         | Qandahar   |{"Population": 237500}  |
| 3    | Herat      | AFG         | Herat      |{"Population": 186800}  |
| ...  |           |             |            |                         |
| 4079 | Rafah      | PSE         | Rafah      |{"Population": 92020}   |
```

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.
Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-py> db.city.select(['Name', 'CountryCode'])
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kabul</td>
<td>AFG</td>
</tr>
<tr>
<td>Qandahar</td>
<td>AFG</td>
</tr>
<tr>
<td>Herat</td>
<td>AFG</td>
</tr>
<tr>
<td>Mazar-e-Sharif</td>
<td>AFG</td>
</tr>
<tr>
<td>Amsterdam</td>
<td>NLD</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Rafah</td>
<td>PSE</td>
</tr>
<tr>
<td>Olympia</td>
<td>USA</td>
</tr>
<tr>
<td>Little Falls</td>
<td>USA</td>
</tr>
<tr>
<td>Happy Valley</td>
<td>USA</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

```
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-py> db.city.select(['Name', 'CountryCode']).where('Name like 'Z%')
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zaanstad</td>
<td>NLD</td>
</tr>
<tr>
<td>Zoetermeer</td>
<td>NLD</td>
</tr>
<tr>
<td>Zwolle</td>
<td>NLD</td>
</tr>
<tr>
<td>Zenica</td>
<td>BIH</td>
</tr>
<tr>
<td>Zagazig</td>
<td>EGY</td>
</tr>
<tr>
<td>Zaragoza</td>
<td>ESP</td>
</tr>
<tr>
<td>Zamboanga</td>
<td>PHL</td>
</tr>
<tr>
<td>Zahedan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zanjan</td>
<td>IRN</td>
</tr>
<tr>
<td>Zabol</td>
<td>IRN</td>
</tr>
<tr>
<td>Zama</td>
<td>JPN</td>
</tr>
<tr>
<td>Zhezqazghan</td>
<td>KAZ</td>
</tr>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

```
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%'
" as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.city.select(['Name', 'CountryCode']).where('Name like :name')
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kabul</td>
<td>AFG</td>
</tr>
<tr>
<td>Qandahar</td>
<td>AFG</td>
</tr>
<tr>
<td>Herat</td>
<td>AFG</td>
</tr>
<tr>
<td>Mazar-e-Sharif</td>
<td>AFG</td>
</tr>
<tr>
<td>Amsterdam</td>
<td>NLD</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Rafah</td>
<td>PSE</td>
</tr>
<tr>
<td>Olympia</td>
<td>USA</td>
</tr>
<tr>
<td>Little Falls</td>
<td>USA</td>
</tr>
<tr>
<td>Happy Valley</td>
<td>USA</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

```
4082 rows in set (0.00 sec)
```

Note: The examples above are generated with Python's `mysql-connector` library for MySQL. The actual code might differ slightly depending on the specific library or tool used.
Relational Tables

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

### Project Results

To issue a query using the **AND** operator, add the operator between search conditions in the `where()` method.

```python
mysql-py> db.city.select(["Name", "CountryCode"]).
    \.where("Name like 'Z%' and CountryCode = 'CHN'"
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuangzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhaozhuang</td>
<td>CHN</td>
</tr>
</tbody>
</table>

...                 ...

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhangjiagang</td>
<td>CHN</td>
</tr>
</tbody>
</table>

22 rows in set (0.01 sec)

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of **AND** and **OR** operators.

```python
mysql-py> db.city.select(["Name", "CountryCode"]).
    \.where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS'"
```

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zhengzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zibo</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiakou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuangzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhuzhou</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhangjiang</td>
<td>CHN</td>
</tr>
<tr>
<td>Zigong</td>
<td>CHN</td>
</tr>
<tr>
<td>Zhaozhuang</td>
<td>CHN</td>
</tr>
</tbody>
</table>

...                 ...

<table>
<thead>
<tr>
<th>Name</th>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zeleznogorsk</td>
<td>RUS</td>
</tr>
</tbody>
</table>

29 rows in set (0.01 sec)

### Limit, Order, and Offset Results

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```python
mysql-py> db.country.select(["Code", "Name"]).limit(5)
```
Relational Tables

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABW</td>
<td>Aruba</td>
</tr>
<tr>
<td>AFG</td>
<td>Afghanistan</td>
</tr>
<tr>
<td>AGO</td>
<td>Angola</td>
</tr>
<tr>
<td>AIA</td>
<td>Anguilla</td>
</tr>
<tr>
<td>ALB</td>
<td>Albania</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order.

```sql
mysql-py> db.country.select(['Code', 'Name']).order_by(['Name desc']).limit(3)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZWE</td>
<td>Zimbabwe</td>
</tr>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```sql
mysql-py> db.country.select(['Code', 'Name']).order_by(['Name desc']).limit(3).offset(1)
```

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZMB</td>
<td>Zambia</td>
</tr>
<tr>
<td>YUG</td>
<td>Yugoslavia</td>
</tr>
<tr>
<td>YEM</td>
<td>Yemen</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

Related Information

- See [TableSelectFunction](https://dev.mysql.com/doc/refman/8.0/en/) for the full syntax definition.

20.4.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```sql
mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Query OK, 1 item affected (0.04 sec)
Relational Tables

Use the select() method to verify the change.
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+------+-----------+-------------+----------+-----------------------------+
| ID
| Name
| CountryCode | District | Info
|
+------+-----------+-------------+----------+-----------------------------+
| 1891 | Beijing
| CHN
| Peking

• See TableUpdateFunction for the full syntax definition.

20.4.4.4 Delete Tables
You can use the delete() method to remove some or all records from a table in a database. The X
DevAPI provides additional methods to use with the delete() method to filter and order the records to be
deleted.

Delete Records Using Conditions
The example that follows passes search conditions to the delete() method. All records matching the
condition will be deleted from the city table. In this example, one record matches the condition.
mysql-py> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)

Delete the First Record
To delete the first record in the city table, use the limit() method with a value of 1.
mysql-py> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)

Delete All Records in a Table
You can delete all records in a table. To do so, use the delete() method without specifying a search
condition.
Caution
Use care when you delete records without specifying a search condition. This action
will delete all records from the table.

Drop a Table
The drop_collection() method is also used in MySQL Shell to drop a relational table from a database.
For example, to drop the citytest table from the world_x database, type:
mysql-py> session.drop_collection("world_x", "citytest")
Query OK (0.04 sec)

Related Information
• See TableDeleteFunction for the full syntax definition.
• See Section 20.4.1, “Import Database Sample” for instructions to recreate the world_x database.

3390


20.4.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native JSON data type.

Examples in this section use the city table in the world_x database.

city Table Description

The city table has five columns (or fields).

```
+---------------+------------+-------+-------+---------+------------------+
| Field         | Type       | Null  | Key   | Default | Extra            |
+---------------+------------+-------+-------+---------+------------------+
| ID            | int(11)    | NO    | PRI   | null    | auto_increment   |
| Name          | char(35)   | NO    |       |         |                  |
| CountryCode   | char(3)    | NO    |       |         |                  |
| District      | char(20)   | NO    |       |         |                  |
| Info          | json       | YES   |       | null    |                  |
+---------------+------------+-------+-------+---------+------------------+
```

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-py> db.city.insert().values(None, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
```

Related Information

- See Working with Relational Tables and Documents for a general overview.
- See Section 11.6, "The JSON Data Type" for a detailed description of the data type.
20.5 X Plugin

This section explains how to use, configure and monitor X Plugin.

20.5.1 Checking X Plugin Installation

Because X Plugin is enabled by default, installing or upgrading to MySQL 8 makes the plugin available. The following shows how to use MySQL Shell and a standard MySQL Client to check if the plugin is installed:

Check the X Plugin Installation

Verify that the X Plugin is installed.

An installed X Plugin is listed in the plugins list on the MySQL server, for example:

MySQL Shell command:

```
shell> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

MySQL Client program command:

```
shell> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

```
+----------------------------+----------+--------------------+---------+---------+
| Name                       | Status   | Type               | Library | License |
|----------------------------+----------+--------------------+---------+---------|
| ...                        |          |                    |         |         |
| mysqlx                     | ACTIVE   | DAEMON             | NULL    | GPL     |
| ...                        |          |                    |         |         |
```

20.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `--WITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

20.5.3 Using Secure Connections with X Plugin

This section explains how to configure X Plugin to use secure connections. For more background information, see Section 6.4, “Using Encrypted Connections”.

X Plugin has its own SSL settings which can differ from those used with MySQL Server. This means that X Plugin can be configured with a different SSL key, certificate, and certificate authorities file than MySQL Server. Similarly, X Plugin has its own SSL status variables calculated independently from the MySQL Server SSL related variables. By default the X Plugin SSL configuration is taken from the `mysqlx_ssl_*` variables, described at Section 20.5.5.2, “X Plugin Options and System Variables”. If no configuration is
Using X Plugin with the Caching SHA-2 Authentication Plugin

provided using the `mysqlx_ssl_*` variables, X Plugin falls back to using the MySQL Server SSL system variables. This means you can choose to either have separate SSL configurations for MySQL Protocol and X Protocol connections by configuring each separately, or share the SSL configuration between MySQL Protocol and X Protocol connections by only configuring the `ssl-*` variables.

On a server with X Plugin installed, to configure MySQL Protocol and X Protocol connections with separate SSL configurations use both the `ssl-*` and `mysqlx-ssl-*` variables in `my.cnf`:

```
[mysqld]
ssl-ca=ca1.pem
ssl-cert=server-cert1.pem
ssl-key=server-key1.pem

mysqlx-ssl-ca=ca2.pem
mysqlx-ssl-cert=server-cert2.pem
mysqlx-ssl-key=server-key2.pem
```

The available `mysqlx_ssl_*` variables mirror the SSL variables in MySQL Server, so the files and techniques described for configuring MySQL Server to use SSL at Section 6.4.1, “Configuring MySQL to Use Encrypted Connections” are relevant to configuring X Plugin to use secure connections.

You can configure the TLS versions used by X Protocol SSL connections using the `tls_version` system variable. The TLS version used by MySQL Protocol and X Protocol connections is therefore the same TLS version.

Encryption per connection is optional, but a specific user can be forced to use encryption for X Protocol and MySQL Protocol connections. You configure such a user by issuing a `GRANT` statement with the `REQUIRE` option. For more details see Section 13.7.1.6, “GRANT Syntax”. Alternatively all X Protocol and MySQL Protocol connections can be forced to use encryption by setting `require_secure_transport`.

20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL accounts created with the Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication” plugin. You can use X Plugin to authenticate against such accounts using non-SSL connections with `SHA256_MEMORY` authentication and SSL connections with `PLAIN` authentication.

Although the caching SHA-2 authentication plugin holds an authentication cache, to use such accounts with X Plugin the X Plugin authentication cache plugin named `mysqlx_cache_cleaner` is used. Like X Plugin, it is enabled by default.

Before you can use non-SSL connections to authenticate an account which uses the `caching_sha2_password` plugin, the account must have authenticated at least once over an SSL connection to store the password in the X Plugin authentication cache. This means that the first use of an account must be done using an SSL connection with the X Plugin authentication cache enabled. Once this initial authentication over SSL has succeeded non-SSL connections can be used.

20.5.5 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin. If values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

20.5.5.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, and system and status variables provided by X Plugin.

#### 20.5.5.2 X Plugin Options and System Variables

To control activation of X Plugin, use this option:

- `--mysqlx [=value]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx [=value]</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.11</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads X Plugin at startup. In MySQL 8.0, X Plugin is enabled by default, but this option may be used to control its activation state.

The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”.

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- `mysqlx_bind_address`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-bind-address=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_bind_address</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
The network address which X Plugin uses for connections. This variable is not dynamic and can only be configured at start up. This is the X Plugin equivalent of `bind_address`; see that variable for more information.

By default X Plugin listens for connections on a single IPv4 TCP/IP network socket. Use this option to configure where X Plugin listens for connections, such as binding to an IPv6 address, all IPv4 and IPv6 addresses or a default IPv6 address with a fallback IPv4 address.

X Plugin treats different types of addresses as follows:

- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default.
- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces. This value is the default.
- If the address is `::`, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections for X Plugin.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to `::ffff:127.0.0.1`, a client such as MySQL Shell can connect using `--host=127.0.0.1` or `--host=::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

```markdown
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--mysqlx-connect-timeout=value</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>mysqlx_connect_timeout</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR Hint Applies</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>30</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>10000000000</td>
</tr>
</tbody>
</table>
```
The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of `connect_timeout`; see that variable for more information.

- **mysqlx_document_id_unique_prefix**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-document-id-unique-prefix=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_document_id_unique_prefix</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See [Understanding Document IDs](#).

- **mysqlx_idle_worker_thread_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-idle-worker-thread-timeout=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_idle_worker_thread_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3600</td>
</tr>
</tbody>
</table>

The number of seconds after which idle worker threads are terminated.

- **mysqlx_interactive_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-interactive-timeout=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_interactive_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
The default value of the `mysqlx_wait_timeout` session variable for interactive clients. (The number of seconds to wait for interactive clients to timeout.)

- **mysqlx_max_allowed_packet**

  Property | Value
  --- | ---
  **SET_VAR** Hint Applies | No
  Type | Integer
  Default Value | 28800
  Minimum Value | 1
  Maximum Value | 2147483

  The maximum size of network packets that can be received by X Plugin. This is the X Plugin equivalent of `max_allowed_packet`; see that variable for more information.

- **mysqlx_max_connections**

  Property | Value
  --- | ---
  **SET_VAR** Hint Applies | No
  Type | Integer
  Default Value | 100
  Minimum Value | 1
  Maximum Value | 65535

  The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of `max_connections`; see that variable for more information.

  For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

- **mysqlx_min_worker_threads**
### X Plugin Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-min-worker-threads=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_min_worker_threads</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The minimum number of worker threads used by X Plugin for handling client requests.

- `mysqlx_port`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-port=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_port</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>33060</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of `port`; see that variable for more information.

- `mysqlx_port_open_timeout`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-port-open-timeout=value</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_port_open_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>120</td>
</tr>
</tbody>
</table>

The number of seconds X Plugin waits for a TCP/IP port to become free.
• `mysqlx_read_timeout`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-read-timeout=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_read_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>30</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, the connection is aborted.

• `mysqlx_socket`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-socket=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_socket</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>/tmp/mysqlx.sock</code></td>
</tr>
</tbody>
</table>

The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default `mysqlx_socket` path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an `x` appended to the file name. The default path and file name for the main socket file is `/tmp/mysql.sock`, therefore the default path and file name for the X Plugin socket file is `/tmp/mysqlx.sock`.

If you specify an alternative path and file name for the main socket file at server startup using the `socket` system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the `mysqlx_socket` system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the `MYSQL_UNIX_ADDR` compile option, this does affect the default for the X Plugin socket file, which is
formed by appending an \texttt{x} to the \texttt{MYSQL_UNIX_ADDR} file name. If you want to set a different default for the X Plugin socket file at compile time, use the \texttt{MYSQL_UNIX_ADDR} compile option.

The \texttt{MYSQL_UNIX_PORT} environment variable can also be used to set a default for the X Plugin socket file at server startup (see Section 4.9, “MySQL Program Environment Variables”). If you set this environment variable, it overrides the compiled \texttt{MYSQL_UNIX_ADDR} value, but is overridden by the \texttt{mysqlx_socket} value.

- \texttt{mysqlx_ssl_ca}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--mysqlx-ssl-ca=file_name}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{mysqlx_ssl_ca}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

This is the X Plugin equivalent of \texttt{ssl_ca}; see that variable for more information.

- \texttt{mysqlx_ssl_capath}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--mysqlx-ssl-capath=dir_name}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{mysqlx_ssl_capath}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

This is the X Plugin equivalent of \texttt{ssl_capath}; see that variable for more information.

- \texttt{mysqlx_ssl_cert}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--mysqlx-ssl-cert=name}</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{mysqlx_ssl_cert}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

This is the X Plugin equivalent of \texttt{ssl_cert}; see that variable for more information.

- \texttt{mysqlx_ssl_cipher}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--mysqlx-ssl-cipher=name}</td>
</tr>
</tbody>
</table>
### mysqlx_ssl_cipher

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mysqlx_ssl_cipher</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The SSL cipher to use for X Protocol connections. This is the X Plugin equivalent of `ssl_cipher`; see that variable for more information.

### mysqlx_ssl_crl

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-ssl-crl=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_ssl_crl</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

This is the X Plugin equivalent of `ssl_crl`; see that variable for more information.

### mysqlx_ssl_crlpath

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-ssl-crlpath=dir_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_ssl_crlpath</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

This is the X Plugin equivalent of `ssl_crlpath`; see that variable for more information.

### mysqlx_ssl_key

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-ssl-key=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>mysqlx_ssl_key</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

This is the X Plugin equivalent of `ssl_key`; see that variable for more information.
### Monitoring X Plugin

- **mysqlx_wait_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-wait-timeout=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_wait_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds that X Plugin waits for activity on a connection. After this time, if the read operation is not successful, the connection is aborted. If the client is noninteractive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.

- **mysqlx_write_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysqlx-write-timeout=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>8.0.4</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysqlx_write_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483</td>
</tr>
</tbody>
</table>

The number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, the connection is aborted.

### 20.5.6 Monitoring X Plugin

This section describes how to monitor X Plugin. There are two available methods of monitoring, using Performance Schema tables or status variables.

#### 20.5.6.1 Status Variables for X Plugin

The status variables have the following meanings.

- **Mysqlx_aborted_clients**
The number of clients that were disconnected because of an input or output error.

- **Mysqlx_address**
  The network address which X Plugin is bound to. If the bind has failed, or if the `skip_networking` option has been used, the value shows **UNDEFINED**.

- **Mysqlx_bytes_received**
  The number of bytes received through the network.

- **Mysqlx_bytes_sent**
  The number of bytes sent through the network.

- **Mysqlx_connection_accept_errors**
  The number of connections which have caused accept errors.

- **Mysqlx_connection_errors**
  The number of connections which have caused errors.

- **Mysqlx_connections_accepted**
  The number of connections which have been accepted.

- **Mysqlx_connections_closed**
  The number of connections which have been closed.

- **Mysqlx_connections_rejected**
  The number of connections which have been rejected.

- **Mysqlx_crud_create_view**
  The number of create view requests received.

- **Mysqlx_crud_delete**
  The number of delete requests received.

- **Mysqlx_crud_drop_view**
  The number of drop view requests received.

- **Mysqlx_crud_find**
  The number of find requests received.

- **Mysqlx_crud_insert**
  The number of insert requests received.

- **Mysqlx_crud_modify_view**
  The number of modify view requests received.
Monitoring X Plugin

- `Mysqlx_crud_update`
  The number of update requests received.

- `Mysqlx_cursor_close`
  The number of cursor-close messages received

- `Mysqlx_cursor_fetch`
  The number of cursor-fetch messages received

- `Mysqlx_cursor_open`
  The number of cursor-open messages received

- `Mysqlx_errors_sent`
  The number of errors sent to clients.

- `Mysqlx_expect_close`
  The number of expectation blocks closed.

- `Mysqlx_expect_open`
  The number of expectation blocks opened.

- `Mysqlx_init_error`
  The number of errors during initialisation.

- `Mysqlx_notice_global_sent`
  The number of global notifications sent to clients.

- `Mysqlx_notice_other_sent`
  The number of other types of notices sent back to clients.

- `Mysqlx_notice_warning_sent`
  The number of warning notices sent back to clients.

- `Mysqlx_notified_by_group_replication`
  Number of Group Replication notifications sent to clients

- `Mysqlx_port`
  The TCP port which X Plugin is listening to. If a network bind has failed, or if the `--skip-networking` option has been used, the value shows UNDEFINED.

- `Mysqlx_prep_deallocate`
  The number of prepared-statement-deallocate messages received

- `Mysqlx_prep_execute`
  The number of prepared-statement-execute messages received
• **Mysqlx_prep_prepare**
  The number of prepared-statement messages received

• **Mysqlx_rows_sent**
  The number of rows sent back to clients.

• **Mysqlx_sessions**
  The number of sessions that have been opened.

• **Mysqlx_sessions_accepted**
  The number of session attempts which have been accepted.

• **Mysqlx_sessions_closed**
  The number of sessions that have been closed.

• **Mysqlx_sessions_fatal_error**
  The number of sessions that have closed with a fatal error.

• **Mysqlx_sessions_killed**
  The number of sessions which have been killed.

• **Mysqlx_sessions_rejected**
  The number of session attempts which have been rejected.

• **Mysqlx_socket**
  The Unix socket which X Plugin is listening to.

• **Mysqlx_ssl_accept_renegotiates**
  The number of negotiations needed to establish the connection.

• **Mysqlx_ssl_accepts**
  The number of accepted SSL connections.

• **Mysqlx_ssl_active**
  If SSL is active.

• **Mysqlx_ssl_cipher**
  The current SSL cipher (empty for non-SSL connections).

• **Mysqlx_ssl_cipher_list**
  A list of possible SSL ciphers (empty for non-SSL connections).

• **Mysqlx_ssl_ctx_verify_depth**
  The certificate verification depth limit currently set in ctx.
• Mysqlx_ssl_ctx_verify_mode
  The certificate verification mode currently set in ctx.

• Mysqlx_ssl_finished_accepts
  The number of successful SSL connections to the server.

• Mysqlx_ssl_server_not_after
  The last date for which the SSL certificate is valid.

• Mysqlx_ssl_server_not_before
  The first date for which the SSL certificate is valid.

• Mysqlx_ssl_verify_depth
  The certificate verification depth for SSL connections.

• Mysqlx_ssl_verify_mode
  The certificate verification mode for SSL connections.

• Mysqlx_ssl_version
  The name of the protocol used for SSL connections.

• Mysqlx_stmt_create_collection
  The number of create collection statements received.

• Mysqlx_stmt_create_collection_index
  The number of create collection index statements received.

• Mysqlx_stmt_disable_notices
  The number of disable notice statements received.

• Mysqlx_stmt_drop_collection
  The number of drop collection statements received.

• Mysqlx_stmt_drop_collection_index
  The number of drop collection index statements received.

• Mysqlx_stmt_enable_notices
  The number of enable notice statements received.

• Mysqlx_stmt_ensure_collection
  The number of ensure collection statements received.

• Mysqlx_stmt_execute_mysqlx
  The number of StmtExecute messages received with namespace set to mysqlx.
- **Mysqlx_stmt_execute_sql**
  The number of StmtExecute requests received for the SQL namespace.

- **Mysqlx_stmt_execute_xplugin**
  The number of StmtExecute requests received for the X Plugin namespace.

- **Mysqlx_stmt_kill_client**
  The number of kill client statements received.

- **Mysqlx_stmt_list_clients**
  The number of list client statements received.

- **Mysqlx_stmt_list_notices**
  The number of list notice statements received.

- **Mysqlx_stmt_list_objects**
  The number of list object statements received.

- **Mysqlx_stmt_ping**
  The number of ping statements received.

- **Mysqlx_worker_threads**
  The number of worker threads available.

- **Mysqlx_worker_threads_active**
  The number of worker threads currently used.

21.5 Known Limitations ............................................................................. 3453

This chapter covers MySQL InnoDB cluster, which combines MySQL technologies to enable you to create highly available clusters of MySQL server instances.

21.1 Introducing InnoDB Cluster

MySQL InnoDB cluster provides a complete high availability solution for MySQL. MySQL Shell includes AdminAPI which enables you to easily configure and administer a group of at least three MySQL server instances to function as an InnoDB cluster. Each MySQL server instance runs MySQL Group Replication, which provides the mechanism to replicate data within InnoDB clusters, with built-in failover. AdminAPI removes the need to work directly with Group Replication in InnoDB clusters, but for more information see Chapter 18, Group Replication which explains the details. MySQL Router can automatically configure itself based on the cluster you deploy, connecting client applications transparently to the server instances. In the event of an unexpected failure of a server instance the cluster reconfigures automatically. In the default single-primary mode, an InnoDB cluster has a single read-write server instance - the primary. Multiple secondary server instances are replicas of the primary. If the primary fails, a secondary is automatically promoted to the role of primary. MySQL Router detects this and forwards client applications to the new primary. Advanced users can also configure a cluster to have multiple-primaries.

Important

InnoDB cluster does not provide support for MySQL NDB Cluster. NDB Cluster depends on the NDB storage engine as well as a number of programs specific to NDB Cluster which are not furnished with MySQL Server 8.0; NDB is available only as part of the MySQL NDB Cluster distribution. In addition, the MySQL server binary (mysqld) that is supplied with MySQL Server 8.0 cannot be used with NDB Cluster. For more information about MySQL NDB Cluster, see Chapter 22, MySQL NDB Cluster 8.0. Section 22.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, provides information about the differences between the InnoDB and NDB storage engines.

The following diagram shows an overview of how these technologies work together:
Figure 21.1 InnoDB cluster overview
Using AdminAPI

MySQL Shell includes the AdminAPI, which is accessed through the `dba` global variable and its associated methods. The `dba` variable's methods enable you to deploy, configure, and administer InnoDB clusters. For example, use the `dba.createCluster()` method to create an InnoDB cluster.

**Important**

MySQL Shell enables you to connect to servers over a socket connection, but AdminAPI requires TCP connections to a server instance. Socket based connections are not supported in AdminAPI.

MySQL Shell provides online help for the AdminAPI. To list all available `dba` commands, use the `dba.help()` method. For online help on a specific method, use the general format `object.help('methodname')`. For example:

```
mysql-js> dba.help('getCluster')
Retrieves a cluster from the Metadata Store.
SYNTAX
    dba.getCluster([name][, options])
WHERE
    name: Parameter to specify the name of the cluster to be returned.
    options: Dictionary with additional options.
RETURNS
    The cluster object identified by the given name or the default cluster.
DESCRIPTION
    If name is not specified or is null, the default cluster will be returned.
    If name is specified, and no cluster with the indicated name is found, an error
    will be raised.
    The options dictionary accepts the `connectToPrimary` option, which defaults to
    true and indicates the shell to automatically connect to the primary member of
    the cluster.
EXCEPTIONS
    MetadataError in the following scenarios:
    - If the Metadata is inaccessible.
    - If the Metadata update operation failed.
    ArgumentError in the following scenarios:
    - If the Cluster name is empty.
    - If the Cluster name is invalid.
    - If the Cluster does not exist.
    RuntimeError in the following scenarios:
    - If the current connection cannot be used for Group Replication.
```
21.2 Creating an InnoDB Cluster

This section explains the different ways you can create an InnoDB cluster, the requirements for server instances and the software you need to install to deploy a cluster.

21.2.1 Deployment Scenarios

InnoDB cluster supports the following deployment scenarios:

- **Production deployment**: if you want to use InnoDB cluster in a full production environment you need to configure the required number of machines and then deploy your server instances to the machines. A production deployment enables you to exploit the high availability features of InnoDB cluster to their full potential. See Section 21.2.4, “Production Deployment of InnoDB Cluster” for instructions.

- **Sandbox deployment**: if you want to test out InnoDB cluster before committing to a full production deployment, the provided sandbox feature enables you to quickly set up a cluster on your local machine. Sandbox server instances are created with the required configuration and you can experiment with InnoDB cluster to become familiar with the technologies employed. See Section 21.2.5, “Sandbox Deployment of InnoDB Cluster” for instructions.

  **Important**

  A sandbox deployment is not suitable for use in a full production environment.

21.2.2 InnoDB Cluster Requirements

Before installing a production deployment of InnoDB cluster, ensure that the server instances you intend to use meet the following requirements.

- InnoDB cluster uses Group Replication and therefore your server instances must meet the same requirements. See Section 18.8.1, “Group Replication Requirements”. AdminAPI provides the `dba.checkInstanceConfiguration()` method to verify that an instance meets the Group Replication requirements, and the `dba.configureInstance()` method to configure an instance to meet the requirements.

  **Note**

  When using a sandbox deployment the instances are configured to meet these requirements automatically.

- Group Replication members can contain tables using a storage engine other than InnoDB, for example MyISAM. Such tables cannot be written to by Group Replication, and therefore when using InnoDB cluster. To be able to write to such tables with InnoDB cluster, convert all such tables to InnoDB before using the instance in a InnoDB cluster.

- The Performance Schema must be enabled on any instance which you want to use with InnoDB cluster.

- The provisioning scripts that MySQL Shell uses to configure servers for use in InnoDB cluster require access to Python version 2.7. For a sandbox deployment Python is required on the single machine used for the deployment, production deployments require Python on each server instance which should run MySQL Shell locally, see Persisting Settings.

  On Windows MySQL Shell includes Python and no user configuration is required. On Unix Python must be found as part of the shell environment. To check that your system has Python configured correctly issue:
Methods of Installing

```bash
$ /usr/bin/env python
```

If a Python interpreter starts, no further action is required. If the previous command fails, create a soft link between `/usr/bin/python` and your chosen Python binary.

### 21.2.3 Methods of Installing

The method you use to install InnoDB cluster depends on the type of deployment you intend to use. For a sandbox deployment install the components of InnoDB cluster to a single machine. A sandbox deployment is local to a single machine, therefore the install needs to only be done once on the local machine. For a production deployment install the components to each machine that you intend to add to your cluster. A production deployment uses multiple remote host machines running MySQL server instances, so you need to connect to each machine using a tool such as SSH or Windows remote desktop to carry out tasks such as installing components. The following methods of installing InnoDB cluster are available:

- Downloading and installing the components using the following documentation:
  - MySQL Server - see Chapter 2, *Installing and Upgrading MySQL*.
  - MySQL Shell - see *Installing MySQL Shell*.
  - MySQL Router - see *Installing MySQL Router*.

- On Windows you can use the MySQL Installer for Windows for a sandbox deployment. For details, see *Group Replication*.

Once you have installed the software required by InnoDB cluster choose to follow either Section 21.2.5, “Sandbox Deployment of InnoDB Cluster” or Section 21.2.4, “Production Deployment of InnoDB Cluster”.

### 21.2.4 Production Deployment of InnoDB Cluster

When working in a production environment, the MySQL server instances which make up an InnoDB cluster run on multiple host machines as part of a network rather than on single machine as described in Section 21.2.5, “Sandbox Deployment of InnoDB Cluster”. Before proceeding with these instructions you must install the required software to each machine that you intend to add as a server instance to your cluster, see Section 21.2.3, “Methods of Installing”.

The following diagram illustrates the scenario you work with in this section:
Important

Unlike a sandbox deployment, where all instances are deployed locally to one machine which AdminAPI has local file access to and can persist configuration changes, for a production deployment you must persist any configuration changes on the instance. How you do this depends on the version of MySQL running on the instance, see Persisting Settings.

To pass a server's connection information to AdminAPI use URI type strings or a data dictionary, see Section 4.2.3, “Connecting Using a URI or Key-Value Pairs”. In this documentation URI type strings are shown.

User Privileges

The user account used to administer an instance does not have to be the root account, however the user needs to be assigned full read and write privileges on the InnoDB cluster metadata tables in addition to full MySQL administrator privileges (SUPER, GRANT OPTION, CREATE, DROP and so on). The preferred method to create users to administer the cluster is using the clusterAdmin option with the dba.configureInstance() and Cluster.addInstance() operations. In this procedure the user ic is shown in examples.

If only read operations are needed (such as for monitoring purposes), an account with more restricted privileges can be used. To give the user your_user the privileges needed to monitor InnoDB cluster issue:

```
grant select on mysql_innodb_cluster_metadata.* to your_user@'%' ;
grant select on performance_schema.global_status to your_user@'%' ;
grant select on performance_schema.replication_applier_configuration to your_user@'%' ;
grant select on performance_schema.replication_applier_status to your_user@'%' ;
grant select on performance_schema.replication_applier_status_by_coordinator to your_user@'%' ;
grant select on performance_schema.replication_applier_status_by_worker to your_user@'%' ;
grant select on performance_schema.replication_connection_configuration to your_user@'%' ;
grant select on performance_schema.replication_connection_status to your_user@'%' ;
grant select on performance_schema.replication_group_member_stats to your_user@'%' ;
grant select on performance_schema.replication_group_members to your_user@'%' ;
grant select on performance_schema.threads to your_user@'%' with grant option ;
```

User Accounts Created by InnoDB Cluster

As part of using Group Replication, InnoDB cluster creates internal users which enable replication between the servers in the cluster. These users are internal to the cluster, and the user name of the generated users follows a naming scheme of mysql_innodb_cluster_r[10_numbers]. The hostname used for the internal users depends on whether the ipWhitelist option has been configured. If ipWhitelist is not configured, it defaults to AUTOMATIC and the internal users are created using both the wildcard % character and localhost for the hostname value. When ipWhitelist has been configured, for each address in the ipWhitelist list an internal user is created. For more information, see Creating a Whitelist of Servers.

Each internal user has a randomly generated password. The randomly generated users are given the following grants:

```
grant replication slave on *.* to internal_user ;
```

The internal user accounts are created on the seed instance and then replicated to the other instances in the cluster. The internal users are:

- generated when creating a new cluster by issuing dba.createCluster()
• generated when adding a new instance to the cluster by issuing `Cluster.addInstance()`.

In addition, the `Cluster.rejoinInstance()` operation can also result in a new internal user being generated when the `ipWhitelist` option is used to specify a hostname. For example by issuing:

```javascript
Cluster.rejoinInstance({ipWhitelist: "192.168.1.1/22"});
```

all previously existing internal users are removed and a new internal user is created, taking into account the `ipWhitelist` value used.

For more information on the internal users required by Group Replication, see Section 18.2.1.3, "User Credentials".

### Configuring Hostname

The production instances which make up a cluster run on separate machines, therefore each machine must have a unique host name and be able to resolve the host names of the other machines which run server instances in the cluster. If this is not the case, you can:

• configure each machine to map the IP of each other machine to a hostname. See your operating system documentation for details. This is the recommended solution.

• set up a DNS service

• configure the `report_host` variable in the MySQL configuration of each instance to a suitable externally reachable address

In this procedure the host name `ic-number` is used in examples.

To verify whether the hostname of a MySQL server is correctly configured, execute the following query to see how the instance reports its own address to other servers and try to connect to that MySQL server from other hosts using the returned address:

```sql
SELECT coalesce(@@report_host, @@hostname);
```

###Persisting Settings

The AdminAPI commands you use to work with a cluster and its server instances modify the configuration of the instance. Depending on the way MySQL Shell is connected to the instance and the version of MySQL installed on the instance, these configuration changes can be persisted to the instance automatically. Persisting settings to the instance ensures that configuration changes are retained after the instance restarts, for background information see `SET PERSIST`. This is essential for reliable cluster usage, for example if settings are not persisted then an instance which has been added to a cluster does not rejoin the cluster after a restart because configuration changes are lost. Persisting changes is required after the following operations:

• `dba.configureInstance()`

• `dba.createCluster()`

• `Cluster.addInstance()`

• `Cluster.removeInstance()`

• `Cluster.rejoinInstance()`

Instances which meet the following requirements support persisting configuration changes automatically:

• the instance is running MySQL version 8.0.11 or later
• **persisted_globals_load** is set to **ON**

Instances which do not meet these requirements do not support persisting configuration changes automatically, when AdminAPI operations result in changes to the instance's settings to be persisted you receive warnings such as:

```plaintext
WARNING: On instance 'localhost:3320' membership change cannot be persisted since MySQL version 5.7.21 does not support the SET PERSIST command (MySQL version => 8.0.5 required). Please use the <Dba>.configureLocalInstance command locally to persist the changes.
```

When AdminAPI commands are issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, MySQL Shell persists configuration changes directly to the instance. On local instances which support persisting configuration changes automatically, configuration changes are persisted to the instance's `mysqld-auto.cnf` file and the configuration change does not require any further steps. On local instances which do not support persisting configuration changes automatically, you need to make the changes locally, see Configuring Instances with `dba.configureLocalInstance()`.

When run against a remote instance, in other words an instance other than the one which MySQL Shell is currently running on, if the instance supports persisting configuration changes automatically, the AdminAPI commands persist configuration changes to the instance's `mysql-auto.conf` option file. If a remote instance does not support persisting configuration changes automatically, the AdminAPI commands can not automatically configure the instance's option file. This means that AdminAPI commands can read information from the instance, for example to display the current configuration, but changes to the configuration cannot be persisted to the instance's option file. In this case, you need to persist the changes locally, see Configuring Instances with `dba.configureLocalInstance()`.

### Verbose Logging

When working with a production deployment it can be useful to configure verbose logging for MySQL Shell, the information in the log can help you to find and resolve any issues that might occur when you are preparing server instances to work as part of InnoDB cluster. To start MySQL Shell with a verbose logging level use the **--log-level** option:

```bash
shell> mysqlsh --log-level=DEBUG3
```

The **DEBUG3** is recommended, see **--log-level** for more information. When **DEBUG3** is set the MySQL Shell log file contains lines such as `Debug: execute_sql( ... )` which contain the SQL queries that are executed as part of each AdminAPI call. The log file generated by MySQL Shell is located in `~/.mysqlsh/mysqlsh.log` for Unix-based systems; on Microsoft Windows systems it is located in `%APPDATA%\MySQL\mysqlsh\mysqlsh.log`. See MySQL Shell Application Log for more information.

In addition to enabling the MySQL Shell log level, you can configure the amount of output AdminAPI provides in MySQL Shell after issuing each command. To enable the amount of AdminAPI output, in MySQL Shell issue:

```bash
mysql-js> dba.verbose=2
```

This enables the maximum output from AdminAPI calls. The available levels of output are:

- **0 or OFF** is the default. This provides minimal output and is the recommended level when not troubleshooting.
- **1 or ON** adds verbose output from each call to the AdminAPI.
Configuring Production Instances

AdminAPI provides the `dba.configureInstance()` function that checks if an instance is suitably configured for InnoDB cluster usage, and configures the instance if it finds any settings which are not compatible with InnoDB cluster. You run the `dba.configureInstance()` command against an instance and it checks all of the settings required to enable the instance to be used for InnoDB cluster usage. If the instance does not require configuration changes, there is no need to modify the configuration of the instance, and the `dba.configureInstance()` command output confirms that the instance is ready for InnoDB cluster usage. If any changes are required to make the instance compatible with InnoDB cluster, a report of the incompatible settings is displayed, and you can choose to let the command make the changes to the instance's option file. Depending on the way MySQL Shell is connected to the instance, and the version of MySQL running on the instance, you can make these changes permanent by persisting them to a remote instance's option file, see Persisting Settings. Instances which do not support persisting configuration changes automatically require that you configure the instance locally, see Configuring Instances with `dba.configureLocalInstance()`. Alternatively you can make the changes to the instance's option file manually, see Section 4.2.7, "Using Option Files" for more information. Regardless of the way you make the configuration changes, you might have to restart MySQL to ensure the configuration changes are detected.

The syntax of the `dba.configureInstance()` command is:

```sql
dba.configureInstance([instance], options)
```

where `instance` is an instance definition, and `options` is a data dictionary with additional options to configure the operation. The command returns a descriptive text message about the operation's result.

The instance definition is the connection data for the instance. If the target instance already belongs to an InnoDB cluster an error is generated and the process fails.

The options dictionary can contain the following:

- `mycnfPath` - the path to the MySQL option file of the instance.
- `outputMycnfPath` - alternative output path to write the MySQL option file of the instance.
- `password` - the password to be used by the connection.
- `clusterAdmin` - the name of an InnoDB cluster administrator user to be created. The supported format is the standard MySQL account name format. Supports identifiers or strings for the user name and host name. By default if unquoted it assumes input is a string.
- `clusterAdminPassword` - the password for the InnoDB cluster administrator account being created using `clusterAdmin`.
- `clearReadOnly` - a boolean value used to confirm that `super_read_only` should be set to off, see Super Read-only and Instances.
- `interactive` - a boolean value used to disable the interactive wizards in the command execution, so that prompts are not provided to the user and confirmation prompts are not shown.
- `restart` - a boolean value used to indicate that a remote restart of the target instance should be performed to finalize the operation.

The connection password can be contained in the instance definition. Alternatively, it can be overwitten by specifying it using the `password` option.
Once `dba.configureInstance()` is issued against an instance, the command checks if the instance's settings are suitable for InnoDB cluster usage. A report is displayed which shows the settings required by InnoDB cluster. If the instance does not require any changes to its settings you can use it in an InnoDB cluster, and can proceed to Creating the Cluster. If the instance's settings are not valid for InnoDB cluster usage the `dba.configureInstance()` command displays the settings which require modification. Before configuring the instance you are prompted to confirm the changes shown in a table with the following information:

- **Variable** - the invalid configuration variable.
- **Current Value** - the current value for the invalid configuration variable.
- **Required Value** - the required value for the configuration variable.

How you proceed depends on whether the instance supports persisting settings, see Persisting Settings. When `dba.configureInstance()` is issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, it attempts to automatically configure the instance. When `dba.configureInstance()` is issued against a remote instance, if the instance supports persisting configuration changes automatically, you can choose to do this. If a remote instance does not support persisting the changes to configure it for InnoDB cluster usage, you have to configure the instance locally. See Configuring Instances with `dba.configureLocalInstance()`.

In general, a restart of the instance is not required after `dba.configureInstance()` configures the option file, but for some specific settings a restart might be required. This information is shown in the report generated after issuing `dba.configureInstance()`. If the instance supports the RESTART statement, MySQL Shell can shutdown and then start the instance. This ensures that the changes made to the instance's option file are detected by mysqld. For more information see RESTART.

**Note**

After executing a **RESTART** statement, the current connection to the instance is lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

The `dba.configureInstance()` method verifies that a suitable user is available for cluster usage, which is used for connections between members of the cluster, see User Privileges. The recommended way to add a suitable user is to use the `clusterAdmin` and `clusterAdminPassword` options, which enable you to configure the cluster user and password when calling the function. For example:

```javascript
mysql-js> dba.configureInstance('ic@ic-1:3306', 
{clusterAdmin: '"icadmin'@'ic-1"', clusterAdminPassword: 'password'});
```

This user is granted the privileges to be able to administer the cluster. The format of the user names accepted follows the standard MySQL account name format, see Section 6.2.4, “Specifying Account Names”.

If you do not specify a user to administer the cluster, in interactive mode a wizard enables you to choose one of the following options:

- enable remote connections for the root user
- create a new user, the equivalent of specifying the `clusterAdmin` and `clusterAdminPassword` options
- no automatic configuration, in which case you need to manually create the user

The following example demonstrates the option to create a new user for cluster usage.
mysql-ja> `dba.configureLocalInstance('root@localhost:3306')`

Please provide the password for 'root@localhost:3306':

Please specify the path to the MySQL configuration file: /etc/mysql/mysql.conf.d/mysqld.cnf
Validating instance...

The configuration has been updated but it is required to restart the server.

```
{  "config_errors": [  
    {  "action": "restart",  
      "current": "OFF",  
      "option": "enforce_gtid_consistency",  
      "required": "ON"  
    },  
    {  "action": "restart",

      "option": "relay_log_info_repository",  
      "required": "TABLE"  
    },  
    {  "action": "restart",  
      "current": "OFF",  
      "option": "transaction_write_set_extraction",  
      "required": "XXHASH64"  
    }  
  
  ]  ,  
  "errors": [],  
  "restart_required": true,  
  "status": "error"
```

`
mysql-ja>
```

**Tip**

If the instance has `super_read_only=ON` then you might need to confirm that 
AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) 
for more information.
Creating the Cluster

Once you have prepared your instances, use the `dba.createCluster()` function to create the cluster. The machine which you are running MySQL Shell on is used as the seed instance for the cluster. The seed instance is replicated to the other instances which you add to the cluster, making them replicas of the seed instance.

MySQL Shell must be connected to an instance before you can create a cluster because when you issue `dba.createCluster(name)` MySQL Shell creates a MySQL protocol session to the server instance connected to the MySQL Shell's current global session. Use the `dba.createCluster(name)` function to create the cluster and assign the returned cluster to a variable called `cluster`:

```javascript
mysql-js> var cluster = dba.createCluster('testCluster')
Validating instance at ic@ic-1:3306...
This instance reports its own address as ic-1
Instance configuration is suitable.
Creating InnoDB cluster 'testCluster' on 'ic@ic-1:3306'...
Adding Seed Instance...
Cluster successfully created. Use Cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to one server failure.
```

The returned Cluster object uses a new session, independent from the MySQL Shell's main session. This ensures that if you change the MySQL Shell global session, the Cluster object maintains its session to the instance.

**Tip**

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See [Super Read-only and Instances](#) for more information.

**Note**

If you encounter an error related to metadata being inaccessible you might have the loopback network interface configured. For correct InnoDB cluster usage disable the loopback interface.

To check the cluster has been created, use the cluster instance's `status()` function. See [Checking a cluster's Status with Cluster.status()](#).

**Tip**

Once server instances belong to a cluster it is important to only administer them using MySQL Shell and AdminAPI. Attempting to manually change the configuration of Group Replication on an instance once it has been added to a cluster is not supported. Similarly, modifying server variables critical to InnoDB cluster, such as `server_uuid` after an instance is configured using AdminAPI is not supported.

When you create a cluster using MySQL Shell 8.0.14 and later, you can set the timeout before instances are expelled from the cluster, for example when they become unreachable. Pass the `expelTimeout` option to the `dba.createCluster()` operation, which configures the `group_replication_member_expel_timeout` variable on the seed instance. The `expelTimeout` option can take an integer value in the range of 0 to 3600. All instances running MySQL server 8.0.13 and
later which are added to a cluster with `expelTimeout` configured are automatically configured to have the same `expelTimeout` value as configured on the seed instance.

### Adding Instances to a Cluster

Use the `cluster.addInstance(instance)` function to add more instances to the cluster, where `instance` is connection information to a configured instance, see Configuring Production Instances. You need a minimum of three instances in the cluster to make it tolerant to the failure of one instance. Adding further instances increases the tolerance to failure of an instance. To add an instance to the cluster issue:

```sql
mysql-js> cluster.addInstance('ic@ic-2:3306')
A new instance will be added to the InnoDB cluster. Depending on the amount of data on the cluster this might take from a few seconds to several hours.

Please provide the password for 'ic@ic-2:3306': ********
Adding instance to the cluster ...
Validating instance at ic-2:3306 ...
This instance reports its own address as ic-2
Instance configuration is suitable.
The instance 'ic@ic-2:3306' was successfully added to the cluster.
```

To verify the instance has been added, use the cluster instance’s `status()` function. For example this is the status output of a sandbox cluster after adding a second instance:

```json
mysql-js> cluster.status()
{
   "clusterName": "testCluster",
   "defaultReplicaSet": {
      "name": "default",
      "primary": "localhost:3310",
      "ssl": "REQUIRED",
      "status": "OK_NO_TOLERANCE",
      "statusText": "Cluster is NOT tolerant to any failures."
   },
   "topology": {
      "localhost:3310": {
         "address": "localhost:3310",
         "mode": "R/W",
         "readReplicas": {},
         "role": "HA",
         "status": "ONLINE"
      },
      "localhost:3320": {
         "address": "localhost:3320",
         "mode": "R/O",
         "readReplicas": {},
         "role": "HA",
         "status": "ONLINE"
      }
   }
   "groupInformationSourceMember": "mysql://root@localhost:3310"
}
```

How you proceed depends on whether the instance is local or remote to the instance MySQL Shell is running on, and whether the instance supports persisting configuration changes automatically, see Persisting Settings. If the instance supports persisting configuration changes automatically, you do not need to persist the settings manually and can either add more instances or continue to the next step. If the instance does not support persisting configuration changes automatically, you have to configure the
instance locally. See Configuring Instances with \texttt{dba.configureLocalInstance()}. This is essential to ensure that instances rejoin the cluster in the event of leaving the cluster.

\textbf{Tip}

If the instance has \texttt{super\_read\_only=ON} then you might need to confirm that AdminAPI can set \texttt{super\_read\_only=OFF}. See Super Read-only and Instances for more information.

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see Section 21.3, “Using MySQL Router with InnoDB Cluster”.

\section*{21.2.5 Sandbox Deployment of InnoDB Cluster}

This section explains how to set up a sandbox InnoDB cluster deployment. You create and administer your InnoDB clusters using MySQL Shell with the included AdminAPI. This section assumes familiarity with MySQL Shell, see MySQL Shell 8.0 (part of MySQL 8.0) for further information.

Initially deploying and using local sandbox instances of MySQL is a good way to start your exploration of InnoDB cluster. You can fully test out InnoDB cluster locally, prior to deployment on your production servers. MySQL Shell has built-in functionality for creating sandbox instances that are correctly configured to work with Group Replication in a locally deployed scenario.

\textbf{Important}

Sandbox instances are only suitable for deploying and running on your local machine for testing purposes. In a production environment the MySQL Server instances are deployed to various host machines on the network. See Section 21.2.4, “Production Deployment of InnoDB Cluster” for more information.

This tutorial shows how to use MySQL Shell to create an InnoDB cluster consisting of three MySQL server instances.

- Deploying Sandbox Instances
- Creating the Sandbox InnoDB Cluster
- Adding Instances to an InnoDB Cluster
- Persisting the Sandbox Configuration

\subsection*{Deploying Sandbox Instances}

MySQL Shell includes the AdminAPI that adds the \texttt{dba} global variable, which provides functions for administration of sandbox instances. In this example setup, you create three sandbox instances using \texttt{dba.deploySandboxInstance()}.

Start MySQL Shell from a command prompt by issuing the command:

\begin{verbatim}
shell> mysqlsh
\end{verbatim}

MySQL Shell provides two scripting language modes, JavaScript and Python, in addition to a native SQL mode. Throughout this guide MySQL Shell is used primarily in JavaScript mode. When MySQL Shell starts it is in JavaScript mode by default. Switch modes by issuing \texttt{\js} for JavaScript mode, \texttt{\py} for Python mode, and \texttt{\sql} for SQL mode. Ensure you are in JavaScript mode by issuing the \texttt{\js} command, then execute:
Creating the Sandbox InnoDB Cluster

The next step is to create the InnoDB cluster while connected to the seed MySQL Server instance. The seed instance contains the data that you want to replicate to the other instances. In this example the sandbox instances are blank, therefore we can choose any instance.

Connect MySQL Shell to the seed instance, in this case the one at port 3310:

```
mysql-\js> \connect root@localhost:3310
```

The \connect MySQL Shell command is a shortcut for the `shell.connect()` method:

```
mysql-\js> shell.connect('user@localhost:3310')
```

Once you have connected, AdminAPI can write to the local instance's option file. This is different to working with a production deployment, where you would need to persist settings to the instance's option file.

Use the `dba.createCluster()` method to create the InnoDB cluster with the currently connected instance as the seed:

```
mysql-\js> var cluster = dba.createCluster('testCluster')
```

The `createCluster()` method deploys the InnoDB cluster metadata to the selected instance, and adds the instance you are currently connected to as the seed instance. The `createCluster()` method
returns the created cluster, in the example above this is assigned to the `cluster` variable. The parameter passed to the `createCluster()` method is a symbolic name given to this InnoDB cluster, in this case `testCluster`.

Tip
If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Adding Instances to an InnoDB Cluster

The next step is to add more instances to the InnoDB cluster. Any transactions that were executed by the seed instance are re-executed by each secondary instance as it is added. This tutorial uses the sandbox instances that were created earlier at ports 3320 and 3330.

The seed instance in this example was recently created, so it is nearly empty. Therefore, there is little data that needs to be replicated from the seed instance to the secondary instances. In a production environment, where you have an existing database on the seed instance, you could use a tool such as MySQL Enterprise Backup to ensure that the secondaries have matching data before replication starts. This avoids the possibility of lengthy delays while data replicates from the primary to the secondaries. See Section 18.4.6, “Using MySQL Enterprise Backup with Group Replication”.

Add the second instance to the InnoDB cluster:

```javascript
mysql-js> cluster.addInstance('root@localhost:3320')
```

The root user's password is prompted for.

Add the third instance:

```javascript
mysql-js> cluster.addInstance('root@localhost:3330')
```

The root user's password is prompted for.

At this point you have created a cluster with three instances: a primary, and two secondaries.

Tip
You can only specify `localhost` in `addInstance()` if the instance is a sandbox instance. This also applies to the implicit `addInstance()` after issuing `createCluster()`.

Persisting the Sandbox Configuration

Once the sandbox instances have been added to the cluster, the configuration required for InnoDB cluster must be persisted to each of the instance's option files. How you proceed depends on whether the instance supports persisting configuration changes automatically, see Persisting Settings. When the MySQL instance which you are using supports persisting configuration changes automatically, adding the instance automatically configures the instance. When the MySQL instance which you are using does not support persisting configuration changes automatically, you have to configure the instance locally. See Configuring Instances with `dba.configureLocalInstance()`.

To check the cluster has been created, use the cluster instance's `status()` function. See Checking a cluster's Status with `Cluster.status()`.
Adopting a Group Replication Deployment

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see Section 21.3, “Using MySQL Router with InnoDB Cluster”.

21.2.6 Adopting a Group Replication Deployment

If you have an existing deployment of Group Replication and you want to use it to create a cluster, pass the `adoptFromGR` option to the `dba.createCluster()` function. The created InnoDB cluster matches whether the replication group is running as single-primary or multi-primary.

To adopt an existing Group Replication group, connect to a group member using MySQL Shell. In the following example a single-primary group is adopted. We connect to `gr-member-2`, a secondary instance, while `gr-member-1` is functioning as the group’s primary. Create a cluster using `dba.createCluster()`, passing in the `adoptFromGR` option. For example:

```mysql-js>
var cluster = dba.createCluster('prodCluster', {adoptFromGR: true});
```

A new InnoDB cluster will be created on instance 'root@gr-member-2:3306'.

Creating InnoDB cluster 'prodCluster' on 'root@gr-member-2:3306'
Adding Seed Instance...
Cluster successfully created. Use cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to one server failure.

**Tip**

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

The new cluster matches the mode of the group. If the adopted group was running in single-primary mode then a single-primary cluster is created. If the adopted group was running in multi-primary mode then a multi-primary cluster is created.

21.3 Using MySQL Router with InnoDB Cluster

This section describes how to use MySQL Router with InnoDB cluster to achieve high availability. Regardless of whether you have deployed a sandbox or production cluster, MySQL Router can configure itself based on the InnoDB cluster's metadata using the `--bootstrap` option. This configures MySQL Router automatically to route connections to the cluster's server instances. Client applications connect to the ports MySQL Router provides, without any need to be aware of the InnoDB cluster topology. In the event of a unexpected failure, the InnoDB cluster adjusts itself automatically and MySQL Router detects the change. This removes the need for your client application to handle failover. For more information, see Routing for MySQL InnoDB cluster.

**Note**

Do not attempt to configure MySQL Router manually to redirect to the ports of an InnoDB cluster. Always use the `--bootstrap` option as this ensures that MySQL Router takes its configuration from the InnoDB cluster's metadata. See Cluster Metadata and State.

The recommended deployment of MySQL Router is on the same host as the application. When using a sandbox deployment, everything is running on a single host, therefore you deploy MySQL Router to the same host. When using a production deployment, we recommend deploying one MySQL Router instance
Using MySQL Router with InnoDB Cluster

to each machine used to host one of your client applications. It is also possible to deploy MySQL Router to a common machine through which your application instances connect.

Assuming MySQL Router is already installed (see Installing MySQL Router), use the `--bootstrap` option to provide the location of a server instance that belongs to the InnoDB cluster. MySQL Router uses the included metadata cache plugin to retrieve the InnoDB cluster's metadata, consisting of a list of server instance addresses which make up the InnoDB cluster and their role in the cluster. You pass the URI type string of the server that MySQL Router should retrieve the InnoDB cluster metadata from. For example:

```shell
mysqlrouter --bootstrap ic@ic-1:3306 --user=mysqlrouter
```

You are prompted for the instance password and encryption key for MySQL Router to use. This encryption key is used to encrypt the instance password used by MySQL Router to connect to the cluster. The ports you can use to connect to the InnoDB cluster are also displayed. The MySQL Router bootstrap process creates a `mysqlrouter.conf` file, with the settings based on the cluster metadata retrieved from the address passed to the `--bootstrap` option, in the above example `ic@ic-1:3306`. Based on the InnoDB cluster metadata retrieved, MySQL Router automatically configures the `mysqlrouter.conf` file, including a `metadata_cache` section with `bootstrap_server_addresses` containing the addresses for all server instances in the cluster. For example:

```
[metadata_cache:prodCluster]
router_id=1
bootstrap_server_addresses=mysql://ic@ic-1:3306,mysql://ic@ic-2:3306,mysql://ic@ic-3:3306
user=mysql_router1_jy95yozko3k2
metadata_cluster=prodCluster
ttl=300
```

**Tip**

When you change the topology of a cluster by adding another server instance after you have bootstrapped MySQL Router, you need to update `bootstrap_server_addresses` based on the updated metadata. Either restart MySQL Router using the `--bootstrap` option, or manually edit the `bootstrap_server_addresses` section of the `mysqlrouter.conf` file and restart MySQL Router.

The generated MySQL Router configuration creates TCP ports which you use to connect to the cluster. Ports for communicating with the cluster using both Classic MySQL protocol and X Protocol are created. To use X Protocol the server instances must have X Plugin installed and configured. For a sandbox deployment, instances have X Plugin set up automatically. For a production deployment, if you want to use X Protocol you need to install and configure X Plugin on each instance, see Installing MySQL Shell. The default available TCP ports are:

- **6446** - for Classic MySQL protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
- **6447** - for Classic MySQL protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.
- **64460** - for X Protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
- **64470** - for X Protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

Depending on your MySQL Router configuration the port numbers might be different to the above. For example if you use the `--conf-base-port` option, or the
Testing High Availability

The way incoming connections are redirected depends on the type of cluster being used. When using a single-primary cluster, by default MySQL Router publishes a X Protocol and a classic protocol port, which clients connect to for read-write sessions and which are redirected to the cluster's single primary. With a multi-primary cluster read-write sessions are redirected to one of the primary instances in a round-robin fashion. For example, this means that the first connection to port 6446 would be redirected to the ic-1 instance, the second connection to port 6446 would be redirected to the ic-2 instance, and so on. For incoming read-only connections MySQL Router redirects connections to one of the secondary instances, also in a round-robin fashion. To modify this behavior see the `routing_strategy` option.

Once bootstrapped and configured, start MySQL Router. If you used a system wide install with the `--bootstrap` option then issue:

```shell
mysqlrouter &
```

If you installed MySQL Router to a directory using the `--directory` option, use the `start.sh` script found in the directory you installed to. Alternatively set up a service to start MySQL Router automatically when the system boots, see Starting MySQL Router. You can now connect a MySQL client, such as MySQL Shell to one of the incoming MySQL Router ports as described above and see how the client gets transparently connected to one of the InnoDB cluster instances.

```shell
mysqlsh --uri root@localhost:6442
```

To verify which instance you are actually connected to, simply issue an SQL query against the `port` status variable.

```mysql
\sql
Switching to SQL mode... Commands end with ;
mysql> select @@port;
+--------+
| @@port |
+--------+
| 3310   |
+--------+
```

Testing High Availability

To test if high availability works, simulate an unexpected halt by killing an instance. The cluster detects the fact that the instance left the cluster and reconfigures itself. Exactly how the cluster reconfigures itself depends on whether you are using a single-primary or multi-primary cluster, and the role the instance serves within the cluster.

In single-primary mode:

- If the current primary leaves the cluster, one of the secondary instances is elected as the new primary, with instances prioritized by the lowest `server_uuid`. MySQL Router redirects read-write connections to the newly elected primary.

- If a current secondary leaves the cluster, MySQL Router stops redirecting read-only connections to the instance.

For more information see Section 18.4.1.1, “Single-Primary Mode”.

In multi-primary mode:
MySQL Router and Metadata Servers

• If a current “R/W” instance leaves the cluster, MySQL Router redirects read-write connections to other primaries. If the instance which left was the last primary in the cluster then the cluster is completely gone and you cannot connect to any MySQL Router port.

For more information see Section 18.4.1.2, “Multi-Primary Mode”.

There are various ways to simulate an instance leaving a cluster, for example you can forcibly stop the MySQL server on an instance, or use the AdminAPI `dba.killSandboxInstance()` if testing a sandbox deployment. In this example assume there is a single-primary sandbox cluster deployment with three server instances and the instance listening at port 3310 is the current primary. Simulate the instance leaving the cluster unexpectedly:

```sql
mysql-js> dba.killSandboxInstance(3310)
```

The cluster detects the change and elects a new primary automatically. Assuming your session is connected to port 6446, the default read-write classic MySQL protocol port, MySQL Router should detect the change to the cluster’s topology and redirect your session to the newly elected primary. To verify this, switch to SQL mode in MySQL Shell using the `\sql` command and select the instance’s `port` variable to check which instance your session has been redirected to. Notice that the first `SELECT` statement fails as the connection to the original primary was lost. This means the current session has been closed, MySQL Shell automatically reconnects for you and when you issue the command again the new port is confirmed.

```sql
mysq-l> \sql
Switching to SQL mode... Commands end with ;
mysq-l> SELECT @@port;
ERROR: 2013 (HY000): Lost connection to MySQL server during query
The global session got disconnected.
Attempting to reconnect to 'root@localhost:6446'...
The global session was successfully reconnected.
mysq-l> SELECT @@port;
+--------+
<table>
<thead>
<tr>
<th>@@port</th>
</tr>
</thead>
<tbody>
<tr>
<td>3330</td>
</tr>
</tbody>
</table>
+--------+
1 row in set (0.00 sec)
```

In this example, the instance at port 3330 has been elected as the new primary. This shows that the InnoDB cluster provided us with automatic failover, that MySQL Router has automatically reconnected us to the new primary instance, and that we have high availability.

MySQL Router and Metadata Servers

When MySQL Router is bootstrapped against a cluster, it records the server instance’s addresses in its configuration file. If any additional instances are added to the cluster after bootstrapping the MySQL Router, they are not automatically detected and therefore are not used for connection routing.

To ensure that newly added instances are routed to correctly you must bootstrap MySQL Router against the cluster to read the updated metadata. This means that you must restart MySQL Router and include the `--bootstrap` option.

21.4 Working with InnoDB Cluster

This section explains how to work with InnoDB cluster, and how to handle common administration tasks.

• Using `dba.checkInstanceConfiguration()`

• Configuring Instances with `dba.configureLocalInstance()`
Using `dba.checkInstanceConfiguration()`

Before creating a production deployment from server instances you need to check that MySQL on each instance is correctly configured. In addition to `dba.configureInstance()`, which checks the configuration as part of configuring an instance, you can use the `dba.checkInstanceConfiguration()` function. This ensures that the instance satisfies the `Section 21.2.2, “InnoDB Cluster Requirements”` without changing any configuration on the instance. This does not check any data that is on the instance, see `Checking Instance State` for more information. The following demonstrates issuing this in a running MySQL Shell:

```bash
mysql> dba.checkInstanceConfiguration('ic@ic-1:3306')
Please provide the password for 'ic@ic-1:3306': ***
Validating MySQL instance at ic-1:3306 for use in an InnoDB cluster...

This instance reports its own address as ic-1
Clients and other cluster members will communicate with it through this address by default.
If this is not correct, the report_host MySQL system variable should be changed.

Checking whether existing tables comply with Group Replication requirements...
No incompatible tables detected
Checking instance configuration...
```
Some configuration options need to be fixed:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Current Value</th>
<th>Required Value</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog_checksum</td>
<td>CRC32</td>
<td>NONE</td>
<td>Update the server variable</td>
</tr>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF</td>
<td>ON</td>
<td>Update read-only variable and restart the server</td>
</tr>
<tr>
<td>gtid_mode</td>
<td>OFF</td>
<td>ON</td>
<td>Update read-only variable and restart the server</td>
</tr>
<tr>
<td>server_id</td>
<td>1</td>
<td></td>
<td>Update read-only variable and restart the server</td>
</tr>
</tbody>
</table>

Please use the `dba.configureInstance()` command to repair these issues.

```json
{
  "config_errors": [
    {
      "action": "server_update",
      "current": "CRC32",
      "option": "binlog_checksum",
      "required": "NONE"
    },
    {
      "action": "restart",
      "current": "OFF",
      "option": "enforce_gtid_consistency",
      "required": "ON"
    },
    {
      "action": "restart",
      "current": "OFF",
      "option": "gtid_mode",
      "required": "ON"
    },
    {
      "action": "restart",
      "current": "1",
      "option": "server_id",
      "required": ""
    }
  ],
  "status": "error"
}
```

Repeat this process for each server instance that you plan to use as part of your cluster. The report generated after running `dba.checkInstanceConfiguration()` provides information about any configuration changes required before you can proceed. The `action` field in the `config_error` section of the report tells you whether MySQL on the instance requires a restart to detect any change made to the configuration file.

**Configuring Instances with `dba.configureLocalInstance()`**

Instances which do not support persisting configuration changes automatically (see Persisting Settings) require you to connect to the server, run MySQL Shell, connect to the instance locally and issue `dba.configureLocalInstance()`. This enables MySQL Shell to modify the instance's option file after running the following commands against a remote instance:

- `dba.configureInstance()`
- `dba.createCluster()`
- `Cluster.addInstance()`
- `Cluster.removeInstance()`
Retrieving an InnoDB cluster with `dba.getCluster()`

- `Cluster.rejoinInstance()`

**Important**

Failing to persist configuration changes to an instance's option file can result in the instance not rejoining the cluster after the next restart.

The recommended method is to log in to the remote machine, for example using SSH, run MySQL Shell as the root user and then connect to the local MySQL server. For example, use the `--uri` option to connect to the local `instance`:

```
shell> sudo -i mysqlsh --uri=instance
```

Alternatively use the `\connect` command to log in to the local instance. Then issue `dba.configureInstance(instance)`, where `instance` is the connection information to the local instance, to persist any changes made to the local instance's option file.

```
mysql-js> dba.configureLocalInstance('ic@ic-2:3306')
```

Repeat this process for each instance in the cluster which does not support persisting configuration changes automatically. For example if you add 2 instances to a cluster which do not support persisting configuration changes automatically, you must connect to each server and persist the configuration changes required for InnoDB cluster before the instance restarts. Similarly if you modify the cluster structure, for example changing the number of instances, you need to repeat this process for each server instance to update the InnoDB cluster metadata accordingly for each instance in the cluster.

Retrieving an InnoDB cluster with `dba.getCluster()`

When you create a cluster using `dba.createCluster()`, the operation returns a Cluster object which can be assigned to a variable. You use this object to work with the cluster, for example to add instances or check the cluster's status. If you want to retrieve a cluster again at a later date, for example after restarting MySQL Shell, use the `dba.getCluster([name],[options])` function. For example:

```
mysql-js> var cluster1 = dba.getCluster()
```

If you do not specify a cluster `name` then the default cluster is returned. By default MySQL Shell attempts to connect to the primary instance of the cluster when you use `dba.getCluster()`. Set the `connectToPrimary` option to configure this behavior. If `connectToPrimary` is `true` and the active global MySQL Shell session is not to a primary instance, the cluster is queried for the primary member and the cluster object connects to it. If there is no quorum in the cluster, the operation fails. If `connectToPrimary` is `false`, the cluster object uses the active session, in other words the same instance as the MySQL Shell's current global session. If `connectToPrimary` is not specified, MySQL Shell treats `connectToPrimary` as `true`, and falls back to `connectToPrimary` being `false`.

To force connecting to a secondary when getting a cluster, establish a connection to the secondary member of the cluster and use the `connectToPrimary` option by issuing:

```
mysql-js> shell.connect(secondary_member)
mysql-js> var cluster1 = dba.getCluster(testCluster, {connectToPrimary:false})
```

**Tip**

Remember that secondary instances have `super_read_only=ON`, so you cannot write changes to them.
Checking a cluster’s Status with `Cluster.status()`

Cluster objects provide the `status()` method that enables you to check how a cluster is running. Before you can check the status of the InnoDB cluster, you need to get a reference to the InnoDB cluster object by connecting to any of its instances. However, if you want to make changes to the configuration of the cluster, you must connect to a "R/W" instance. Issuing `status()` retrieves the status of the cluster based on the view of the cluster which the server instance you are connected to is aware of and outputs a status report.

⚠️ Important

The instance’s state in the cluster directly influences the information provided in the status report. Therefore ensure the instance you are connected to has a status of `ONLINE`.

For information about how the InnoDB cluster is running, use the cluster’s `status()` method:

```
mysql-js> var cluster = dba.getCluster()
mysql-js> cluster.status()
{
    "clusterName": "testcluster",
    "defaultReplicaSet": {
        "name": "default",
        "primary": "ic-1:3306",
        "ssl": "REQUIRED",
        "status": "OK",
        "statusText": "Cluster is ONLINE and can tolerate up to ONE failure.",
        "topology": {
            "ic-1:3306": {
                "address": "ic-1:3306",
                "mode": "R/W",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            },
            "ic-2:3306": {
                "address": "ic-2:3306",
                "mode": "R/O",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            },
            "ic-3:3306": {
                "address": "ic-3:3306",
                "mode": "R/O",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            }
        },
        "groupInformationSourceMember": "mysql://ic@ic-1:3306"
    }
}
```

The output of `Cluster.status()` provides the following information:

- **clusterName**: name assigned to this cluster during `dba.createCluster()`.
- **defaultReplicaSet**: the server instances which belong to an InnoDB cluster and contain the data set.
- **primary**: displayed when the cluster is operating in single-primary mode only. Shows the address of the current primary instance. If this field is not displayed, the cluster is operating in multi-primary mode.
Checking a cluster's Status with `Cluster.status()`

- **ssl**: whether secure connections are used by the cluster or not. Shows values of **REQUIRED** or **DISABLED**, depending on how the `memberSslMode` option was configured during either `createCluster()` or `addInstance()`. The value returned by this parameter corresponds to the value of the `group_replication_ssl_mode` server variable on the instance. See [Securing your Cluster](#).

- **status**: The status of this element of the cluster. For the overall cluster this describes the high availability provided by this cluster. The status is one of the following:
  - **ONLINE**: The instance is online and participating in the cluster.
  - **OFFLINE**: The instance has lost connection to the other instances.
  - **RECOVERING**: The instance is attempting to synchronize with the cluster by retrieving transactions it needs before it can become an **ONLINE** member.
  - **UNREACHABLE**: The instance has lost communication with the cluster.
  - **ERROR**: The instance has encountered an error during the recovery phase or while applying a transaction.

  **Important**
  Once an instance enters **ERROR** state, the `super_read_only` option is set to **ON**. To leave the **ERROR** state you must manually configure the instance with `super_read_only=OFF`.

- **(MISSING)**: The state of an instance which is part of the configured cluster, but is currently unavailable.

  **Note**
  The **MISSING** state is specific to InnoDB cluster, it is not a state generated by Group Replication. MySQL Shell uses this state to indicate instances that are registered in the metadata, but cannot be found in the live cluster view.

- **topology**: The instances which have been added to the cluster.

- **Host name of instance**: The host name of an instance, for example localhost:3310.

- **role**: what function this instance provides in the cluster. Currently only HA, for high availability.

- **mode**: whether the server is read-write ("R/W") or read-only ("R/O"). The mode indicates either **R/W** (read and writable) or **R/O** (read only). In single-primary mode, only the one instance marked "R/W" can execute transactions that update the database, so it is the primary. If that instance becomes unreachable for any reason (like an unexpected halt), one of the remaining "R/O" instances automatically takes over its place and becomes the new "R/W" primary. In multi-primary mode, all instances are marked as "R/W" and there is no single elected primary.

- **groupInformationSourceMember**: the internal connection used to get information about the cluster, shown as a URI-type string. Usually the connection initially used to create the cluster.

The output of the `Cluster.status()` operation can be extended to enable you to display information about the underlying Group Replication group used by the cluster. To see information about the `groupName` and `memberId`; and general statistics about the number of transactions checked, proposed, and rejected by instances issue:

```
Cluster.status({extended:true})
```
Checking a cluster's Status with \texttt{Cluster.status()}

To see information about recovery and regular transaction I/O, applier worker thread statistics and any lags; applier coordinator statistics, if parallel apply is enabled; error, and other information from I/O and applier threads issue

\texttt{Cluster.status{{queryMembers:true}}}

When \texttt{queryMembers} is set to \texttt{true}, a connection to each instance in the cluster is opened so that additional instance specific statistics can be queried. The exact statistics that are included in the output depend on the state and configuration of the instance and the server version. This information matches that shown in the \texttt{replication_group_member_stats} table, see the descriptions of the matching columns. Instances which are \texttt{ONLINE} have a \texttt{transactions} object included in the output. Instances which are \texttt{RECOVERING} have a \texttt{recovery} object included in the output. In either case, the objects can contain the following:

- \texttt{appliedCount}: see \texttt{COUNT_TRANSACTIONS_REMOTE_APPLIED}
- \texttt{checkedCount}: see \texttt{COUNT_TRANSACTIONS_CHECKED}
- \texttt{committedAllMembers}: see \texttt{TRANSACTIONS_COMMITTED_ALL_MEMBERS}
- \texttt{conflictsDetectedCount}: see \texttt{COUNT_CONFLICTS_DETECTED}
- \texttt{inApplierQueueCount}: see \texttt{COUNT_TRANSACTIONS_REMOTE_IN_APPLIER_QUEUE}
- \texttt{inQueueCount}: see \texttt{COUNT_TRANSACTIONS_IN_QUEUE}
- \texttt{lastConflictFree}: see \texttt{LAST_CONFLICT_FREE TRANSACTION}
- \texttt{proposedCount}: see \texttt{COUNT_TRANSACTIONS_LOCAL_PROPOSED}
- \texttt{rollbackCount}: see \texttt{COUNT_TRANSACTIONS_LOCAL_ROLLBACK}

The \texttt{connection} section shows information from the \texttt{replication_connection_status} table.

The \texttt{currentlyQueueing} section has information about the transactions currently queued:

- \texttt{immediateCommitTimestamp}: see \texttt{QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP}
- \texttt{immediateCommitToNowTime}: see \texttt{QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP} minus \texttt{NOW()}
- \texttt{originalCommitTimestamp}: see \texttt{QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP}
- \texttt{originalCommitToNowTime}: see \texttt{QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP} minus \texttt{NOW()}
- \texttt{startTimestamp}: see \texttt{QUEUEING_TRANSACTION_START_QUEUE_TIMESTAMP}
- \texttt{transaction}: see \texttt{QUEUEING_TRANSACTION}
- \texttt{lastHeartbeatTimestamp}: see \texttt{LAST_HEARTBEAT_TIMESTAMP}

The \texttt{lastQueued} section has information about the most recently queued transaction:

- \texttt{endTimestamp}: see \texttt{LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP}
- \texttt{lastHeartbeatTimestamp}: see \texttt{LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP}
Checking a cluster's Status with `Cluster.status()`

- **immediateCommitToEndTime**: `LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- **originalCommitTimestamp**: see `LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToEndTime**: `LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- **queueTime**: `LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP` minus `LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP`
- **startTimestamp**: see `LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP`
- **transaction**: see `LAST_QUEUED_TRANSACTION`
- **receivedHeartbeats**: see `COUNT_RECEIVED_HEARTBEATS`
- **receivedTransactionSet**: see `RECEIVED_TRANSACTION_SET`
- **threadId**: see `THREAD_ID`

Instances which are using a multithreaded slave have a **workers** section which contains information about the worker threads, and matches the information shown by the `replication_applier_status_by_worker` table.

The **lastApplied** section shows the following information about the the last transaction applied by the worker:

- **applyTime**: see `LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP` minus `LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`
- **endTimestamp**: see `LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP`
- **immediateCommitTimestamp**: see `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- **immediateCommitToEndTime**: see `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- **originalCommitTimestamp**: see `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToEndTime**: `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- **startTimestamp**: see `LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`
- **transaction**: see `LAST_APPLIED_TRANSACTION`

The **currentlyApplying** section shows the following information about the transaction currently being applied by the worker:

- **immediateCommitTimestamp**: see `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- **immediateCommitToNowTime**: see `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- **originalCommitTimestamp**: see `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- **originalCommitToNowTime**: see `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
Checking a cluster’s Status with `Cluster.status()`

- `startTimestamp`: see `APPLYING_TRANSACTION_START_APPLY_TIMESTAMP`
- `transaction`: see `APPLYING_TRANSACTION`

The `lastProcessed` section has the following information about the last transaction processed by the worker:

- `bufferTime`: `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP`
- `endTimestamp`: see `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- `immediateCommitTimestamp`: see `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToEndTime`: `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- `originalCommitTimestamp`: see `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToEndTime`: `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`
- `startTimestamp`: see `LAST_PROCESSED.Transaction.START_BUFFER_TIMESTAMP`
- `transaction`: see `LAST_PROCESSED_TRANSACTION`

If parallel applier workers are enabled, then the number of objects in the workers array in `transactions` or `recovery` matches the number of configured workers and an additional coordinator object is included. The information shown matches the information in the `replication_applier_status_by_coordinator` table. The object can contain:

The `currentlyProcessing` section has the following information about the transaction being processed by the worker:

- `immediateCommitTimestamp`: see `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`
- `immediateCommitToNowTime`: `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP` minus `NOW()`
- `originalCommitTimestamp`: see `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`
- `originalCommitToNowTime`: `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP` minus `NOW()`
- `startTimestamp`: see `PROCESSING_TRANSACTION_START_BUFFER_TIMESTAMP`
- `transaction`: see `PROCESSING_TRANSACTION`

Worker objects have the following information if an error was detected in the `replication_applier_status_by_worker` table:

- `lastErrno`: see `LAST_ERROR_NUMBER`
- `lastError`: see `LAST_ERROR_MESSAGE`
- `lastErrorTimestamp`: see `LAST_ERROR_TIMESTAMP`
connection objects have the following information if an error was detected in the replication_connection_status table:

- lastErrno: see LAST_ERROR_NUMBER
- lastError: see LAST_ERROR_MESSAGE
- lastErrorTimestamp: see LAST_ERROR_TIMESTAMP

coordinator objects have the following information if an error was detected in the replication_applier_status_by_coordinator table:

- lastErrno: see LAST_ERROR_NUMBER
- lastError: see LAST_ERROR_MESSAGE
- lastErrorTimestamp: see LAST_ERROR_TIMESTAMP

Using `cluster.describe()`

To get information about the structure of the InnoDB cluster itself, use the `Cluster.describe()` function:

```javascript
mysql-js> cluster.describe();
{
  "clusterName": "testCluster",
  "defaultReplicaSet": {
    "name": "default",
    "topology": [
      {
        "address": "ic-1:3306",
        "label": "ic-1:3306",
        "role": "HA"
      },
      {
        "address": "ic-2:3306",
        "label": "ic-2:3306",
        "role": "HA"
      },
      {
        "address": "ic-3:3306",
        "label": "ic-3:3306",
        "role": "HA"
      }
    ]
  }
}
```

The output from this function shows the structure of the InnoDB cluster including all of its configuration information, and so on. The address, label and role values match those described at Checking a cluster’s Status with `Cluster.status()`.

Super Read-only and Instances

Whenever Group Replication stops, the `super_read_only` variable is set to ON to ensure no writes are made to the instance. When you try to use such an instance with the following AdminAPI commands you are given the choice to set `super_read_only=OFF` on the instance:

- `dba.configureInstance()`
- `dba.configureLocalInstance()`
Managing Sandbox Instances

- `dba.createCluster()`
- `dba.rebootClusterFromCompleteOutage()`
- `dba.dropMetadataSchema()`

When AdminAPI encounters an instance which has `super_read_only=ON`, in interactive mode you are given the choice to set `super_read_only=OFF`. For example:

```javascript
mysql-js> var myCluster = dba.createCluster('testCluster')
A new InnoDB cluster will be created on instance 'ic@ic-1:3306'.

The MySQL instance at 'ic@ic-1:3306' currently has the super_read_only system variable set to protect it from inadvertent updates from applications.
You must first unset it to be able to perform any changes to this instance.
For more information see: https://dev.mysql.com/doc/refman/en/server-system-variables.html#sysvar_super_read_only.

Note: there are open sessions to 'ic@ic-1:3306'.
You may want to kill these sessions to prevent them from performing unexpected updates:
1 open session(s) of 'ic@ic-1:3306'.

Do you want to disable super_read_only and continue? [y|N]:
```

The number of current active sessions to the instance is shown. You must ensure that no applications might write to the instance inadvertently. By answering \texttt{y} you confirm that AdminAPI can write to the instance. If there is more than one open session to the instance listed, exercise caution before permitting AdminAPI to set `super_read_only=OFF`.

To force the function to set `super_read_only=OFF` in a script, pass the `clearReadOnly` option set to `true`. For example `dba.configureInstance(instance, {clearReadOnly: true})`.

Managing Sandbox Instances

Once a sandbox instance is running, it is possible to change its status at any time using the following:

- To stop a sandbox instance use `dba.stopSandboxInstance(instance)`. This stops the instance gracefully, unlike `dba.killSandboxInstance(instance)`.

- To start a sandbox instance use `dba.startSandboxInstance(instance)`.

- To kill a sandbox instance use `dba.killSandboxInstance(instance)`. This stops the instance without gracefully stopping it and is useful in simulating unexpected halts.

- To delete a sandbox instance use `dba.deleteSandboxInstance(instance)`. This completely removes the sandbox instance from your file system.

Removing Instances from the InnoDB Cluster

You can remove an instance from a cluster at any time should you wish to do so. This can be done with the `Cluster.removeInstance(instance)` method, as in the following example:

```javascript
mysql-js> cluster.removeInstance('root@localhost:3310')
```

The instance will be removed from the InnoDB cluster. Depending on the instance being the Seed or not, the Metadata session might become invalid. If so, please start a new session to the Metadata Storage R/W instance.
Attempting to leave from the Group Replication group...
The instance 'localhost:3310' was successfully removed from the cluster.

You can optionally pass in the `interactive` option to control whether you are prompted to confirm the removal of the instance from the cluster. In interactive mode, you are prompted to continue with the removal of the instance (or not) in case it is not reachable. The `cluster.removeInstance()` operation ensures that the instance is removed from the metadata of all the cluster members which are `ONLINE`, and the instance itself.

When the instance being removed has transactions which still need to be applied, AdminAPI waits for up to the number of seconds configured by the MySQL Shell `dba.gtidWaitTimeout` option for transactions (GTIDs) to be applied. The MySQL Shell `dba.gtidWaitTimeout` option has a default value of 60 seconds, see Configuring MySQL Shell for information on changing the default. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is `false` (or not defined) then an error is issued and the remove operation is aborted. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is set to `true` then the operation continues without an error and removes the instance from the cluster.

---

**Important**

The `force` option should only be used with `Cluster.removeInstance(instance)` when you want to ignore any errors, for example unprocessed transactions or an instance being `UNREACHABLE`, and do not plan to reuse the instance with the cluster. Ignoring errors when removing an instance from the cluster could result in an instance which is not in synchrony with the cluster, preventing it from rejoining the cluster at a later time. Only use the `force` option when you plan to no longer use the instance with the cluster, in all other cases you should always try to recover the instance and only remove it when it is available and healthy, in other words with the status `ONLINE`.

---

**Customizing InnoDB clusters**

When you create a cluster and add instances to it, values such as the group name, the local address, and the seed instances are configured automatically by AdminAPI. These default values are recommended for most deployments, but advanced users can override the defaults by passing the following options to the `dba.createCluster()` and `Cluster.addInstance()`.

To customize the name of the replication group created by InnoDB cluster, pass the `groupName` option to the `dba.createCluster()` command. This sets the `group_replication_group_name` system variable. The name must be a valid UUID.

To customize the address which an instance provides for connections from other instances, pass the `localAddress` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Specify the address in the format `host:port`. This sets the `group_replication_local_address` system variable on the instance. The address must be accessible to all instances in the cluster, and must be reserved for internal cluster communication only. In other words do not use this address for communication with the instance.

To customize the instances used as seeds when an instance joins the cluster, pass the `groupSeeds` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Seed instances are contacted when a new instance joins a cluster and used to provide data to the new instance. The addresses are specified as a comma separated list such as `host1:port1,host2:port2`. This configures the `group_replication_group_seeds` system variable.
For more information see the documentation of the system variables configured by these AdminAPI options.

Rejoining a Cluster

If an instance leaves the cluster, for example because it lost connection, and for some reason it could not automatically rejoin the cluster, it might be necessary to rejoin it to the cluster at a later stage. To rejoin an instance to a cluster issue `Cluster.rejoinInstance(instance)`.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See `Super Read-only and Instances` for more information.

In the case where an instance has not had its configuration persisted (see `Persisting Settings`), upon restart the instance does not rejoin the cluster automatically. The solution is to issue `cluster.rejoinInstance()` so that the instance is added to the cluster again and ensure the changes are persisted. Once the InnoDB cluster configuration is persisted to the instance’s option file it rejoins the cluster automatically.

If you are rejoining an instance which has changed in some way then you might have to modify the instance to make the rejoin process work correctly. For example, when you restore a MySQL Enterprise Backup backup, the `server_uuid` changes. Attempting to rejoin such an instance fails because InnoDB cluster instances are identified by the `server_uuid` variable. In such a situation, information about the instance’s old `server_uuid` must be removed from the InnoDB cluster metadata and then a `Cluster.rescan()` must be executed to add the instance to the metadata using its new `server_uuid`. For example:

```sql
cluster.removeInstance("root@instanceWithOldUUID:3306", {force: true})
cluster.rescan()
```

In this case you must pass the `force` option to the `Cluster.removeInstance()` method because the instance is unreachable from the cluster’s perspective and we want to remove it from the InnoDB cluster metadata anyway.

Restoring a Cluster from Quorum Loss

If an instance (or instances) fail, then a cluster can lose its quorum, which is the ability to vote in a new primary. If you have an instance which contains the InnoDB cluster metadata, it is possible to restore the cluster. This assumes you can connect to an instance that contains the InnoDB cluster metadata, and that instance can contact the other instances you want to use to restore the cluster.

Important

This operation is potentially dangerous because it can create a split-brain scenario if incorrectly used and should be considered a last resort. Make absolutely sure that there are no partitions of this group that are still operating somewhere in the network, but not accessible from your location.

You connect to an instance which contains the cluster’s metadata, then use the `Cluster.forceQuorumUsingPartitionOf(instance)` operation, which restores the cluster based on the metadata on `instance`, and then all the instances that are `ONLINE` from the point of view of the given instance definition are added to the restored cluster.
In the event that an instance is not automatically added to the cluster, for example if its settings were not persisted, use `Cluster.rejoinInstance()` to manually add the instance back to the cluster.

The restored cluster might not, and does not have to, consist of all of the original instances which made up the cluster. For example, if the original cluster consisted of the following five instances:

- ic-1
- ic-2
- ic-3
- ic-4
- ic-5

and the cluster experiences a split-brain scenario, with `ic-1, ic-2, and ic-3 forming one partition while ic-4 and ic-5 form another partition. If you connect to `ic-1 and issue `Cluster.forceQuorumUsingPartitionOf('ic@ic-1:3306') to restore the cluster the resulting cluster would consist of these three instances:

- ic-1
- ic-2
- ic-3

because `ic-1 sees ic-2 and ic-3 as ONLINE and does not see ic-4 and ic-5.

**Rebooting a Cluster from a Major Outage**

If your cluster suffers from a complete outage, you can ensure it is reconfigured correctly using `dba.rebootClusterFromCompleteOutage()`. In the event that a cluster has completely stopped, the instances must be started and only then can the cluster be started. For example if the machine a sandbox cluster was running on has been restarted, and the instances were at ports 3310, 3320 and 3330, issue:

```sql
mysql-js> dba.startSandboxInstance(3310)
mysql-js> dba.startSandboxInstance(3320)
mysql-js> dba.startSandboxInstance(3330)
```

This ensures the sandbox instances are running. In the case of a production deployment you would have to start the instances outside of MySQL Shell. Once the instances have started, connect to an instance and run MySQL Shell. Then restart the cluster by issuing:
Rescanning a Cluster

mysql-js> var cluster = dba.rebootClusterFromCompleteOutage();

Tip
If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

This ensures the cluster is correctly reconfigured after a complete outage. It uses the instance that MySQL Shell is connected to as the new seed instance and recovers the cluster based on the existing metadata of that instance.

If this process fails, and the cluster metadata has become badly corrupted, you might need to drop the metadata and create the cluster again from scratch. You can drop the cluster metadata using `dba.dropMetadataSchema()`.

Warning
The `dba.dropMetadataSchema()` method should only be used as a last resort, when it is not possible to restore the cluster. It cannot be undone.

Rescanning a Cluster

If you make configuration changes to a cluster outside of the AdminAPI commands, for example by changing an instance's configuration manually to resolve configuration issues or after the loss of an instance, you need to update the InnoDB cluster metadata so that it matches the current configuration of instances. In these cases, use the `Cluster.rescan()` operation, which enables you to update the InnoDB cluster metadata either manually or using an interactive wizard. The `Cluster.rescan()` operation can detect new active instances that are not registered in the metadata and add them, or obsolete instances (no longer active) still registered in the metadata, and remove them. You can automatically update the metadata depending on the instances found by the command, or you can specify a list of instance addresses to either add to the metadata or remove from the metadata. You can also update the topology mode stored in the metadata, for example after changing from single-primary mode to multi-primary mode outside of AdminAPI.

The syntax of the command is `Cluster.rescan([options])`. The `options` dictionary supports the following:

- **interactive**: boolean value used to disable or enable the wizards in the command execution. Controls whether prompts and confirmations are provided. The default value is equal to MySQL Shell wizard mode, specified by `shell.options.useWizards`.

- **addInstances**: list with the connection data of the new active instances to add to the metadata, or “auto” to automatically add missing instances to the metadata. The value “auto” is case-insensitive.
  - Instances specified in the list are added to the metadata, without prompting for confirmation.
  - In interactive mode, you are prompted to confirm the addition of newly discovered instances that are not included in the `addInstances` option.
  - In non-interactive mode, newly discovered instances that are not included in the `addInstances` option are reported in the output, but you are not prompted to add them.

- **removeInstances**: list with the connection data of the obsolete instances to remove from the metadata, or “auto” to automatically remove obsolete instances from the metadata.
Checking Instance State

- Instances specified in the list are removed from the metadata, without prompting for confirmation.

- In interactive mode, you are prompted to confirm the removal of obsolete instances that are not included in the `removeInstances` option.

- In non-interactive mode, obsolete instances that are not included in the `removeInstances` option are reported in the output but you are not prompted to remove them.

- `updateTopologyMode`: boolean value used to indicate if the topology mode (single-primary or multi-primary) in the metadata should be updated (true) or not (false) to match the one being used by the cluster. By default, the metadata is not updated (false).

  - If the value is `true` then the InnoDB cluster metadata is compared to the current mode being used by Group Replication, and the metadata is updated if necessary. Use this option to update the metadata after making changes to the topology mode of your cluster outside of AdminAPI.

  - If the value is `false` then InnoDB cluster metadata about the cluster's topology mode is not updated even if it is different from the topology used by the cluster's Group Replication group.

- If the option is not specified and the topology mode in the metadata is different from the topology used by the cluster's Group Replication group, then:
  - In interactive mode, you are prompted to confirm the update of the topology mode in the metadata.
  - In non-interactive mode, if there is a difference between the topology used by the cluster's Group Replication group and the InnoDB cluster metadata, it is reported and no changes are made to the metadata.

- When the metadata topology mode is updated to match the Group Replication mode, the auto-increment settings on all instances are updated in the following way:
  - If the topology mode changed to single-primary then the `auto_increment_increment` is set to 1 and the `auto_increment_offset` is set to 2.
  - If the topology mode changed to multi-primary then the `auto_increment_increment` is set to `n` and the `auto_increment_offset` is set to `1 + server_id % n`. The value of `n` is set to 7 if the number of cluster members equal to or less than 7, otherwise it is set to the number of cluster instances.

Checking Instance State

The `cluster.checkInstanceState()` function can be used to verify the existing data on an instance does not prevent it from joining a cluster. This process works by validating the instance's global transaction identifier (GTID) state compared to the GTIDs already processed by the cluster. For more information on GTIDs see Section 17.1.3.1, “GTID Format and Storage”. This check enables you to determine if an instance which has processed transactions can be added to the cluster.

The following demonstrates issuing this in a running MySQL Shell:

```sql
mysql> cluster.checkInstanceState('ic@ic-4:3306')
```

The output of this function can be one of the following:

- **OK new**: the instance has not executed any GTID transactions, therefore it cannot conflict with the GTIDs executed by the cluster.
• OK recoverable: the instance has executed GTIDs which do not conflict with the executed GTIDs of the cluster seed instances

• ERROR diverged: the instance has executed GTIDs which diverge with the executed GTIDs of the cluster seed instances

• ERROR lost_transactions: the instance has more executed GTIDs than the executed GTIDs of the cluster seed instances

Instances with an OK status can be added to the cluster because any data on the instance is consistent with the cluster. In other words the instance being checked has not executed any transactions which conflict with the GTIDs executed by the cluster, and can be recovered to the same state as the rest of the cluster instances.

Dissolving an InnoDB Cluster

To dissolve an InnoDB cluster you connect to a read-write instance, for example the primary in a single-primary cluster, and use the `Cluster.dissolve()` command. This removes all metadata and configuration associated with the cluster, and disables Group Replication on the instances. Any data that was replicated between the instances is not removed.

Important

There is no way to undo the dissolving of a cluster. To create it again use `dba.createCluster()`.

The `Cluster.dissolve()` operation can only configure instances which are ONLINE or reachable. If members of a cluster cannot be reached by the member where you issued the `Cluster.dissolve()` command you have to decide how the dissolve operation should proceed. If there is any chance you want to rejoin any instances that are identified as missing from the cluster, it is strongly recommended to cancel the dissolve operation and first bring the missing instances back online, before proceeding with a dissolve operation. This ensures that all instances can have their metadata updated correctly, and that there is no chance of a split-brain situation. However, if the instances from the cluster which cannot be reached have permanently left the cluster there could be no choice but to force the dissolve operation, which means that the missing instances are ignored and only online instances are affected by the operation.

Warning

Forcing the dissolve operation to ignore cluster instances can result in instances which could not be reached during the dissolve operation continuing to operate, creating the risk of a split-brain situation. Only ever force a dissolve operation to ignore missing instances if you are sure there is no chance of the instance coming online again.

In interactive mode, if members of a cluster are not reachable during a dissolve operation then an interactive prompt is displayed, for example:

```bash
mysql-js> Cluster.dissolve()
The cluster still has the following registered ReplicaSets:
{
    "clusterName": "testCluster",
    "defaultReplicaSet": {
        "name": "default",
        "topology": [
            {
                "address": "ic-1:3306",
                "label": "ic-1:3306",
            }
        ]
    }
```
Dissolving an InnoDB Cluster

```
{
  "role": "HA",
  {
    "address": "ic-2:3306",
    "label": "ic-2:3306",
    "role": "HA"
  },
  {
    "address": "ic-3:3306",
    "label": "ic-3:3306",
    "role": "HA"
  }
}
```

WARNING: You are about to dissolve the whole cluster and lose the high availability features provided by it. This operation cannot be reverted. All members will be removed from their ReplicaSet and replication will be stopped, internal recovery user accounts and the cluster metadata will be dropped. User data will be maintained intact in all instances.

Are you sure you want to dissolve the cluster? [y/N]: y

ERROR: The instance 'ic-2:3306' cannot be removed because it is on a '(MISSING)' state. Please bring the instance back ONLINE and try to dissolve the cluster again. If the instance is permanently not reachable, then you can choose to proceed with the operation and only remove the instance from the Cluster Metadata.

Do you want to continue anyway (only the instance metadata will be removed)? [y/N]: y

Instance 'ic-3:3306' is attempting to leave the cluster... Instance 'ic-1:3306' is attempting to leave the cluster...

WARNING: The cluster was successfully dissolved, but the following instance was skipped: 'ic-2:3306'. Please make sure this instance is permanently unavailable or take any necessary manual action to ensure the cluster is fully dissolved.

In this example, the cluster consisted of three instances, one of which was offline when dissolve was issued. The error is caught, and you are given the choice how to proceed. In this case the missing ic-2 instance is ignored and the reachable members have their metadata updated.

When MySQL Shell is running in non-interactive mode, for example when running a batch file, you can configure the behavior of the `Cluster.dissolve()` operation using the `force` option. To force the dissolve operation to ignore any instances which are unreachable, issue:

```
mysql-js> Cluster.dissolve({force: true})
```

Any instances which can be reached are removed from the cluster, and any unreachable instances are ignored. The warnings in this section about forcing the removal of missing instances from a cluster apply equally to this technique of forcing the dissolve operation.

You can also use the `interactive` option with the `Cluster.dissolve()` operation to override the mode which MySQL Shell is running in, for example to make the interactive prompt appear when running a batch script. For example:

```
mysql-js> Cluster.dissolve({interactive: true})
```

The `dba.gtidWaitTimeout` MySQL Shell option configures how long the `Cluster.dissolve()` operation waits for cluster transactions to be applied before removing a target instance from the cluster, but only if the target instance is `ONLINE`. An error is issued if the timeout is reached when waiting for cluster transactions.
transactions to be applied on any of the instances being removed, except if force: true is used, which skips the error in that case.

**Note**
After issuing `cluster.dissolve()`, any variable assigned to the `Cluster` object is no longer valid.

## Securing your Cluster

Server instances can be configured to use secure connections. For general information on using SSL with MySQL see Section 6.4, “Using Encrypted Connections”. This section explains how to configure a cluster to use SSL. An additional security possibility is to configure which servers can access the cluster, see Creating a Whitelist of Servers.

**Important**
Once you have configured a cluster to use SSL you must add the servers to the `ipWhitelist`.

When using `dba.createCluster()` to set up a cluster, if the server instance provides SSL encryption then it is automatically enabled on the seed instance. Pass the `memberSslMode` option to the `dba.createCluster()` method to specify a different SSL mode. The SSL mode of a cluster can only be set at the time of creation. The `memberSslMode` option is a string that configures the SSL mode to be used, it defaults to `AUTO`. The permitted values are `DISABLED`, `REQUIRED`, and `AUTO`. These modes are defined as:

- Setting `createCluster({memberSslMode:'DISABLED'})` ensures SSL encryption is disabled for the seed instance in the cluster.
- Setting `createCluster({memberSslMode:'REQUIRED'})` then SSL encryption is enabled for the seed instance in the cluster. If it cannot be enabled an error is raised.
- Setting `createCluster({memberSslMode:'AUTO'})` (the default) then SSL encryption is automatically enabled if the server instance supports it, or disabled if the server does not support it.

**Note**
When using the commercial version of MySQL, SSL is enabled by default and you might need to configure the whitelist for all instances. See Creating a Whitelist of Servers.

When you issue the `cluster.addInstance()` and `cluster.rejoinInstance()` commands, SSL encryption on the instance is enabled or disabled based on the setting found for the seed instance.

When using `createCluster()` with the `adoptFromGR` option to adopt an existing Group Replication group, no SSL settings are changed on the adopted cluster:

- `memberSslMode` cannot be used with `adoptFromGR`.
- If the SSL settings of the adopted cluster are different from the ones supported by the MySQL Shell, in other words SSL for Group Replication recovery and Group Communication, both settings are not modified. This means you are not be able to add new instances to the cluster, unless you change the settings manually for the adopted cluster.

MySQL Shell always enables or disables SSL for the cluster for both Group Replication recovery and Group Communication, see Section 18.5.2, “Secure Socket Layer Support (SSL)”. A verification is
performed and an error issued in case those settings are different for the seed instance (for example as the result of a `dba.createCluster()` using `adoptFromGR`) when adding a new instance to the cluster. SSL encryption must be enabled or disabled for all instances in the cluster. Verifications are performed to ensure that this invariant holds when adding a new instance to the cluster.

The `deploySandboxInstance()` command attempts to deploy sandbox instances with SSL encryption support by default. If it is not possible, the server instance is deployed without SSL support. Use the `ignoreSslError` option set to false to ensure that sandbox instances are deployed with SSL support, issuing an error if SSL support cannot be provided. When `ignoreSslError` is true, which is the default, no error is issued during the operation if the SSL support cannot be provided and the server instance is deployed without SSL support.

Creating a Whitelist of Servers

When using a cluster's `createCluster()`, `addInstance()`, and `rejoinInstance()` methods you can optionally specify a list of approved servers that belong to the cluster, referred to as a whitelist. By specifying the whitelist explicitly in this way you can increase the security of your cluster because only servers in the whitelist can connect to the cluster. Using the `ipWhitelist` option configures the `group_replication_ip_whitelist` system variable on the instance. By default, if not specified explicitly, the whitelist is automatically set to the private network addresses that the server has network interfaces on. To configure the whitelist, specify the servers to add with the `ipWhitelist` option when using the method. Pass the servers as a comma separated list, surrounded by quotes. For example:

```
mysql-js> cluster.addInstance("ic@ic-3:3306", {ipWhitelist: "203.0.113.0/24, 198.51.100.110"})
```

This configures the instance to only accept connections from servers at addresses 203.0.113.0/24 and 198.51.100.110. The whitelist can also include host names, which are resolved only when a connection request is made by another server.

**Warning**

Host names are inherently less secure than IP addresses in a whitelist. MySQL carries out FCrDNS verification, which provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

Scripting AdminAPI

You can automate cluster configuration with scripts, which can be run using MySQL Shell. For example:

```
shell> mysqlsh -f setup-innodb-cluster.js
```

**Note**

Any command line options specified after the script file name are passed to the script and not to MySQL Shell. You can access those options using the `os.argv` array in JavaScript, or the `sys.argv` array in Python. In both cases, the first option picked up in the array is the script name.

The contents of an example script file is shown here:

```
print('MySQL InnoDB cluster sandbox set up\n');
```
Configuring the Election Process

You can optionally configure how a single-primary cluster elects a new primary, for example to prefer one instance as the new primary to fail over to. Use the `memberWeight` option and pass it to the `dba.createCluster()` and `Cluster.addInstance()` methods when creating your cluster. The `memberWeight` option accepts an integer value between 0 and 100, which is a percentage weight for automatic primary election on failover. When an instance has a higher percentage number set by `memberWeight`, it is more likely to be elected as primary in a single-primary cluster. When a primary election takes place, if multiple instances have the same `memberWeight` value, the instances are then prioritized based on their server UUID in lexicographical order (the lowest) and by picking the first one.

Setting the value of `memberWeight` configures the `group_replication_member_weight` system variable on the instance. Group Replication limits the value range from 0 to 100, automatically adjusting it if a higher or lower value is provided. Group Replication uses a default value of 50 if no value is provided. See Section 18.4.1.1, “Single-Primary Mode” for more information.

For example to configure a cluster where `ic-3` is the preferred instance to fail over to in the event that `ic-1`, the current primary, leaves the cluster unexpectedly use `memberWeight` as follows:

```javascript
dba.createCluster('cluster1', {memberWeight:35})
var mycluster = dba.getCluster()
mycluster.addInstance('ic@ic2', {memberWeight:25})
mycluster.addInstance('ic@ic3', {memberWeight:50})```

Changing a Cluster's Topology

By default, an InnoDB cluster runs in single-primary mode, where the cluster has one primary server that accepts read and write queries (R/W), and all of the remaining instances in the cluster accept only read
Setting Options for InnoDB cluster

queries (R/O). When you configure a cluster to run in multi-primary mode, all of the instances in the cluster are primaries, which means that they accept both read and write queries (R/W). If a cluster has all of its instances running MySQL server version 8.0.15 or later, you can make changes to the topology of the cluster while the cluster is online. In previous versions it was necessary to completely dissolve and re-create the cluster to make the configuration changes. This uses the group action coordinator exposed through the UDFs described at Section 18.4.2, “Configuring an Online Group”, and as such you should observe the rules for configuring online groups.

Note
multi-primary mode is considered an advanced mode

Usually a single-primary cluster elects a new primary when the current primary leaves the cluster unexpectedly, for example due to an unexpected halt. The election process is normally used to choose which of the current secondaries becomes the new primary. To override the election process and force a specific server to become the new primary, use the `Cluster.setPrimaryInstance(instance)` function, where `instance` specifies the connection to the instance which should become the new primary. This enables you to configure the underlying Group Replication group to choose a specific instance as the new primary, bypassing the election process.

You can change the mode (sometimes described as the topology) which a cluster is running in between single-primary and multi-primary using the following operations:

- `Cluster.switchToMultiPrimaryMode()`, which switches the cluster to multi-primary mode. All instances become primaries.

- `Cluster.switchToSinglePrimaryMode(instance)`, which switches the cluster to single-primary mode. If `instance` is specified, it becomes the primary and all the other instances become secondaries. If `instance` is not specified, the new primary is the instance with the highest member weight (and the lowest UUID in case of a tie on member weight).

### Setting Options for InnoDB cluster

You can check and modify the settings in place for an InnoDB cluster while the instances are online. To check the current settings of a cluster, use the following operation:

- `Cluster.options()`, which lists the cluster configuration options for its ReplicaSets and instances. A boolean option `all` can also be specified to include information about all Group Replication system variables in the output.

You can configure the options of an InnoDB cluster at a cluster level or instance level, while instances remain online. This avoids the need to remove, reconfigure and then again add the instance to change InnoDB cluster options. Use the following operations:

- `Cluster.setOption(option, value)` to change the settings of all cluster instances globally or cluster global settings such as `clusterName`.

- `Cluster.setInstanceOption(instance, option, value)` to change the settings of individual cluster instances

The way which you use InnoDB cluster options with the operations listed depends on whether the option can be changed to be the same on all instances or not. These options are changeable at both the cluster (all instances) and per instance level:

- `exitStateAction`
• **memberWeight**

This option is changeable at the per instance level only:

• **label**

These options are changeable at the cluster level only:

• **failoverConsistency**
• **expelTimeout**
• **clusterName**

### 21.5 Known Limitations

This section describes the known limitations of InnoDB cluster. As InnoDB cluster uses Group Replication, you should also be aware of its limitations, see Section 18.8.2, “Group Replication Limitations”:

• If a session type is not specified when creating the global session, MySQL Shell provides automatic protocol detection which attempts to first create a NodeSession and if that fails it tries to create a ClassicSession. With an InnoDB cluster that consists of three server instances, where there is one read-write port and two read-only ports, this can cause MySQL Shell to only connect to one of the read-only instances. Therefore it is recommended to always specify the session type when creating the global session.

• When adding non-sandbox server instances (instances which you have configured manually rather than using `dba.deploySandboxInstance()`) to a cluster, MySQL Shell is not able to persist any configuration changes in the instance’s configuration file. This leads to one or both of the following scenarios:

1. The Group Replication configuration is not persisted in the instance’s configuration file and upon restart the instance does not rejoin the cluster.

2. The instance is not valid for cluster usage. Although the instance can be verified with `dba.checkInstanceConfiguration()`, and MySQL Shell makes the required configuration changes in order to make the instance ready for cluster usage, those changes are not persisted in the configuration file and so are lost once a restart happens.

If only a happens, the instance does not rejoin the cluster after a restart.

If b also happens, and you observe that the instance did not rejoin the cluster after a restart, you cannot use the recommended `dba.rebootClusterFromCompleteOutage()` in this situation to get the cluster back online. This is because the instance loses any configuration changes made by MySQL Shell, and because they were not persisted, the instance reverts to the previous state before being configured for the cluster. This causes Group Replication to stop responding, and eventually the command times out.

To avoid this problem it is strongly recommended to use `dba.configureInstance()` before adding instances to a cluster in order to persist the configuration changes.

• The use of the **--defaults-extra-file** option to specify an option file is not supported by InnoDB cluster server instances.
Chapter 22 MySQL NDB Cluster 8.0

Table of Contents

22.1 NDB Cluster Overview ............................................................. 3459
22.1.1 NDB Cluster Core Concepts .................................................... 3461
22.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions ................. 3463
22.1.3 NDB Cluster Hardware, Software, and Networking Requirements .......... 3466
22.1.4 What is New in NDB Cluster ...................................................... 3468
22.1.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0 3472
22.1.6 MySQL Server Using InnoDB Compared with NDB Cluster ......................... 3473
22.1.7 Known Limitations of NDB Cluster ............................................... 3476
22.2 NDB Cluster Installation .......................................................... 3486
22.2.1 The NDB Cluster Auto-Installer ............................................... 3488
22.2.2 Installation of NDB Cluster on Linux ......................................... 3511
22.2.3 Installing NDB Cluster on Windows .......................................... 3520
22.2.4 Initial Configuration of NDB Cluster ........................................... 3529
22.2.5 Initial Startup of NDB Cluster ................................................... 3531
22.2.6 NDB Cluster Example with Tables and Data .................................... 3532
22.2.7 Safe Shutdown and Restart of NDB Cluster ..................................... 3536
22.2.8 Upgrading and Downgrading NDB Cluster ..................................... 3537
22.3 Configuration of NDB Cluster ..................................................... 3537
22.3.1 Quick Test Setup of NDB Cluster .............................................. 3538
22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables 3540
22.3.3 NDB Cluster Configuration Files .............................................. 3557
22.3.4 Using High-Speed Interconnects with NDB Cluster ........................... 3742
22.4 NDB Cluster Programs ............................................................ 3743
22.4.1 ndbd — The NDB Cluster Data Node Daemon ................................... 3743
22.4.2 ndbinfo_select_all — Select From ndbinfos Tables ............................. 3751
22.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded) ............. 3753
22.4.4 ndb_mgmd — The NDB Cluster Management Server Daemon .................... 3754
22.4.5 ndb_mgm — The NDB Cluster Management Client .............................. 3763
22.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables 3765
22.4.7 ndb_config — Extract NDB Cluster Configuration Information ................. 3767
22.4.8 ndb_delete_all — Delete All Rows from an NDB Table ........................ 3777
22.4.9 ndb_desc — Describe NDB Tables .............................................. 3777
22.4.10 ndb_drop_index — Drop Index from an NDB Table ........................... 3784
22.4.11 ndb_drop_table — Drop an NDB Table ......................................... 3785
22.4.12 ndb_error_reporter — NDB Error-Reporting Utility .......................... 3785
22.4.13 ndb_import — Import CSV Data Into NDB ................................... 3787
22.4.14 ndb_index_stat — NDB Index Statistics Utility ................................ 3801
22.4.15 ndb_move_data — NDB Data Copy Utility .................................... 3806
22.4.16 ndb_perror — Obtain NDB Error Message Information ........................ 3809
22.4.17 ndb_print_backup_file — Print NDB Backup File Contents ..................... 3811
22.4.18 ndb_print_file — Print NDB Disk Data File Contents .......................... 3812
22.4.19 ndb_print_frag_file — Print NDB Fragment List File Contents ................. 3812
22.4.20 ndb_print_schema_file — Print NDB Schema File Contents .................. 3813
22.4.21 ndb_print_sys_file — Print NDB System File Contents ........................ 3814
22.4.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log .......... 3814
22.4.23 ndb_restore — Restore an NDB Cluster Backup ................................ 3817
22.4.24 ndb_select_all — Print Rows from an NDB Table ............................ 3839
22.4.25 ndb_select_count — Print Row Counts for NDB Tables ........................ 3842
Support for the NDB storage engine is not included in standard MySQL Server 8.0 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions.
NDB Cluster 8.0 users who build from source should use the sources provided for MySQL 8.0 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

Important

MySQL NDB Cluster does not support InnoDB cluster, which must be deployed using MySQL Server 8.0 with the InnoDB storage engine as well as additional applications that are not included in the NDB Cluster distribution. MySQL Server 8.0 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB cluster, see Chapter 21, InnoDB Cluster. Section 22.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, discusses differences between the NDB and InnoDB storage engines.

This chapter contains information about NDB Cluster 8.0 releases through 8.0.15-ndb-8.0.15, currently available as a Developer Preview. NDB Cluster 7.6 is the latest General Availability release, and is recommended for new deployments; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4. NDB Cluster 7.2 is a previous GA release series which is still maintained, although we recommend that new deployments for production use NDB Cluster 7.6. For more information about NDB Cluster 7.2, see MySQL NDB Cluster 7.2.

Supported Platforms. NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

NDB Cluster release numbers. NDB 8.0 follows the same release pattern as the MySQL Server 8.0 series of releases, beginning with MySQL 8.0.13 and MySQL NDB Cluster 8.0.13. In this Manual and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the NDBCLUSTER storage engine used in the NDB 8.0 release, and is the same as the MySQL 8.0 server version on which the NDB Cluster 8.0 release is based.

Version strings used in NDB Cluster software. The version string displayed by the mysql client supplied with the MySQL NDB Cluster distribution uses this format:

```
mysql-mysql_server_version-cluster
```

mysql_server_version represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is 8.0.\(n\), where \(n\) is the release number. Building from source using -DWITH_NDBCLUSTER or the equivalent adds the -cluster suffix to the version string. (See Section 22.2.2.4, “Building NDB Cluster from Source on Linux”, and Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.) You can see this format used in the mysql client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 8.0.15-cluster Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```
The first release of NDB Cluster using MySQL 8.0 was NDB 8.0.13, which used MySQL 8.0.13.

The version string displayed by other NDB Cluster programs not normally included with the MySQL 8.0 distribution uses this format:

```
mysql-mysql_server_version ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is 8.0.\(n\), where \(n\) is the release number. `ndb_engine_version` is the version of the NDB storage engine used by this release of the NDB Cluster software. For all NDB 8.0 releases, this number is the same as the MySQL Server version. You can see this format used in the output of the `SHOW` command in the `ndb_mgm` client, like this:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1  @10.0.10.6  (mysql-8.0.17 ndb-8.0.15-ndb-8.0.15, Nodegroup: 0, *)
id=2  @10.0.10.8  (mysql-8.0.17 ndb-8.0.15-ndb-8.0.15, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3  @10.0.10.2  (mysql-8.0.17 ndb-8.0.15-ndb-8.0.15)

[mysqld(API)] 2 node(s)
id=4  @10.0.10.10  (mysql-8.0.17 ndb-8.0.15-ndb-8.0.15)
id=5 (not connected, accepting connect from any host)
```

Compatibility with standard MySQL 8.0 releases. While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 22.1.7, "Known Limitations of NDB Cluster"). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. A `mysqld` compiled without NDB support (that is, built without `-DWITH_NDBCLUSTER_STORAGE_ENGINE` or its alias `-DWITH_NDBCLUSTER`) cannot function as a drop-in replacement for a `mysqld` that is built with it.

NDB Cluster development source trees. NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

Note

As with MySQL Server 8.0, NDB Cluster 8.0 releases are built using CMake.

NDB Cluster 7.5 and NDB Cluster 7.6 are available as General Availability (GA) releases; NDB 7.6 is recommended for new deployments. NDB Cluster 7.4 and NDB Cluster 7.3 are previous GA releases.
which are still supported in production. NDB 7.2 is a previous GA release series which is still maintained; it is no longer recommended for new deployments. For an overview of major features added in NDB 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. For information about previous NDB Cluster releases, see MySQL NDB Cluster 7.3 and NDB Cluster 7.4, and MySQL NDB Cluster 7.2.

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at http://www.mysql.com/products/cluster/.

Additional Resources. More information about NDB Cluster can be found in the following places:

• For answers to some commonly asked questions about NDB Cluster, see Section A.10, “MySQL 8.0 FAQ: NDB Cluster”.

• The NDB Cluster mailing list: http://lists.mysql.com/cluster.

• Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through PlanetMySQL.

22.1 NDB Cluster Overview

NDB Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network DataBase”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

An NDB Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:
NDB Cluster Overview

Figure 22.1 NDB Cluster Components

All these programs work together to form an NDB Cluster (see Section 22.4, “NDB Cluster Programs”). When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the mysqld server daemon, it differs in a number of critical respects from the mysqld binary supplied with the MySQL 8.0 distributions, and the two versions of mysqld are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the NDB storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Back up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the ndb_restore program included in the NDB Cluster distribution. For more information, see Section 22.5.3, “Online Backup of NDB Cluster”, and Section 22.4.23, “ndb_restore — Restore an NDB Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in mysqldump and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.
22.1.1 NDB Cluster Core Concepts

*NDBCluster* (also known as *NDB*) is an in-memory storage engine offering high-availability and data-persistence features.

The *NDBCluster* storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's *NDB* storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a node.

**Note**

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term cluster host.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 22.4.1, “*ndbd* — The NDB Cluster Data Node Daemon”) or `ndbmtd` (see Section 22.4.3, “*ndbmtd* — The NDB Cluster Data Node Daemon (Multi-Threaded)”).

  NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an in-memory database). However, some NDB Cluster data can be stored on disk; see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the *NDBCluster* storage engine. An SQL node is a `mysql` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

  An SQL node is actually just a specialized type of API node, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

**Important**

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.
For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the NDBCLUSTER storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the NDB API, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

NDB-specific Java applications can also be written for NDB Cluster using the NDB Cluster Connector for Java. This NDB Cluster Connector includes ClusterJ, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to NDBCLUSTER, and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for ClusterJPA, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL’s query optimizer are sent through the MySQL Server, using JDBC. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the NDB storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

The Memcache API for NDB Cluster, implemented as the loadable ndbmemcache storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard memcached caching engine is included in the NDB Cluster 8.0 distribution. Each memcached server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.
Management clients. These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the ndb_mgm management client supplied with NDB Cluster (see Section 22.4.5, "ndb_mgm — The NDB Cluster Management Client"). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to NDB Cluster. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

Event logs. NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 22.5.6, “Event Reports Generated in NDB Cluster”. Event logs are of the two types listed here:

- **Cluster log**: Keeps a record of all desired reportable events for the cluster as a whole.
- **Node log**: A separate log which is also kept for each individual node.

**Note**

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint. Generally speaking, when data is saved to disk, it is said that a **checkpoint** has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- **Local Checkpoint (LCP)**: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

  NDB 8.0 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the EnablePartialLcp and RecoveryWork configuration parameters which enable partial LCPs and control the amount of storage they use.

- **Global Checkpoint (GCP)**: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see NDB Cluster Data Node File System Directory Files.

### 22.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.
**Data node.** An ndbd or ndbmtd process, which stores one or more replicas—that is, copies of the partitions (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an ndbd or ndbmtd process; where mentioned, management nodes (ndb_mgmd processes) and SQL nodes (mysqld processes) are specified as such in this discussion.

**Node group.** A node group consists of one or more nodes, and stores partitions, or sets of replicas (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (NoOfReplicas configuration parameter), as shown here:

\[
\text{[# of node groups]} = \frac{\text{[# of data nodes]}}{\text{NoOfReplicas}}
\]

Thus, an NDB Cluster with 4 data nodes has 4 node groups if NoOfReplicas is set to 1 in the config.ini file, 2 node groups if NoOfReplicas is set to 2, and 1 node group if NoOfReplicas is set to 4. Replicas are discussed later in this section; for more information about NoOfReplicas, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

**Note**

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”, for more information.

**Partition.** This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

\[
\text{[# of partitions]} = \text{[# of data nodes]} \times \text{[# of LDM threads]}
\]

When using data nodes running ndbmtd, the number of LDM threads is controlled by the setting for MaxNoOfExecutionThreads. When using ndbd there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using ndbmtd with MaxNoOfExecutionThreads set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of MaxNoOfExecutionThreads for more information.)

**NDB and user-defined partitioning.** NDB Cluster normally partitions NDBCLUSTER tables automatically. However, it is also possible to employ user-defined partitioning with NDBCLUSTER tables. This is subject to the following limitations:

1. Only the KEY and LINEAR KEY partitioning schemes are supported in production with NDB tables.

2. The maximum number of partitions that may be defined explicitly for any NDB table is \(8 \times \text{MaxNoOfExecutionThreads} \times [\text{number of node groups}]\), the number of node groups in an NDB Cluster being determined as discussed previously in this section. When using ndbd for data node processes, setting MaxNoOfExecutionThreads has no effect; in such a case, it can be treated as though it were equal to 1 for purposes of performing this calculation.
See Section 22.4.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)", for more information.

For more information relating to NDB Cluster and user-defined partitioning, see Section 22.1.7, “Known Limitations of NDB Cluster”, and Section 23.6.2, “Partitioning Limitations Relating to Storage Engines”.

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

![NDB Cluster with Two Node Groups](image)

**Note**

Only data nodes are shown here; although a working NDB Cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
• Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

• Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.

• Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 22.3 Nodes Required for a 2x2 NDB Cluster**

![Diagram of a 2x2 NDB Cluster]

In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of ndbd. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster "alive". However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

### 22.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating
systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at https://dev.mysql.com/downloads/cluster/.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere. See Section 22.5.1.2.1, “NDB Cluster Security and Networking Issues”, for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.
LAN environments can typically be configured with stable low latency, and such that they can provide
redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled
latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a
range of latencies, as well as redundancy with slower failover times. Individual link failures may require
route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as
large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related
to the worst-case time for the IP layer to reroute around the failures.

22.1.4 What is New in NDB Cluster

The following sections describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 8.0
through 8.0.15, as compared to earlier release series. NDB Cluster 8.0 is currently available in a Developer
Preview release. NDB Cluster 7.6 is available as a General Availability release, as is NDB Cluster 7.5 For
information about additions and other changes in NDB Cluster 7.6, see What is New in NDB Cluster 7.5; for
information about new features and other changes in NDB Cluster 7.5, see What is New in NDB Cluster
7.6.

NDB Cluster 7.4 and 7.3 are recent General Availability releases, and are still supported. NDB Cluster
7.2 is a previous GA release, still supported in production for existing deployments. NDB 7.1 and earlier releases series are no longer maintained or supported in production. We recommend that new
deployments use NDB Cluster 7.6 or NDB Cluster 7.5. For information about NDB 7.4 and NDB 7.3, see
MySQL NDB Cluster 7.3 and NDB Cluster 7.4. For information about NDB 7.2 and previous NDB releases,
see MySQL NDB Cluster 7.2.

What is New in NDB Cluster 8.0

Major changes and new features in NDB Cluster 8.0 which are likely to be of interest are shown in the
following list:

• INFORMATION_SCHEMA changes. The following changes are made in the display of information
about Disk Data files in the INFORMATION_SCHEMA.FILES table:
  • Tablespaces and log file groups are no longer represented in the FILES table. (These constructs are
not actually files.)
  • Each data file is now represented by a single row in the FILES table. Each undo log file is also now
represented in this table by one row only. (Previously, a row was displayed for each copy of each of
these files on each data node.)
  • For rows corresponding to data files or undo log files, node ID and undo log buffer information is no
longer displayed in the EXTRA column of the FILES table.

In addition, INFORMATION_SCHEMA tables now are populated with tablespace statistics for MySQL
Cluster tables. (Bug #27167728)

• Error information with ndb_perror. Removed the deprecated --ndb option for perror. Use
ndb_perror to obtain error message information from NDB error codes instead. (Bug #81704, Bug
#81705, Bug #23523926, Bug #23523957)

• Development in parallel with MySQL server. Beginning with this release, MySQL NDB Cluster is
being developed in parallel with the standard MySQL 8.0 server under a new unified release model with
the following features:
  • NDB 8.0 is developed in, built from, and released with the MySQL 8.0 source code tree.
  • The numbering scheme for NDB Cluster 8.0 releases follows the scheme for MySQL 8.0, starting with
the current MySQL release (8.0.13).
What is New in NDB Cluster

- Building the source with NDB support appends `-cluster` to the version string returned by `mysql -V`, as shown here:

```
shell> mysql -V
mysql  Ver 8.0.13-cluster for Linux on x86_64 (Source distribution)
```

NDB binaries continue to display both the MySQL Server version and the NDB engine version, like this:

```
shell> ndb_mgm -V
MySQL distrib mysql-8.0.13 ndb-8.0.13-dmr, for Linux (x86_64)
```

In MySQL Cluster NDB 8.0, these two version numbers are always the same.

To build the MySQL 8.0.13 (or later) source with NDB Cluster support, use the CMake option `-DWITH_NDBCLUSTER`.

- **Offline multithreaded index builds.** It is now possible to specify a set of cores to be used for I/O threads performing offline multithreaded builds of ordered indexes, as opposed to normal I/O duties such as file I/O, compression, or decompression. “Offline” in this context refers to building of ordered indexes performed when the parent table is not being written to; such building takes place when an NDB cluster performs a node or system restart, or as part of restoring a cluster from backup using `ndb_restore --rebuild-indexes`.

In addition, the default behaviour for offline index build work is modified to use all cores available to `ndbmtd`, rather limiting itself to the core reserved for the I/O thread. Doing so can improve restart and restore times and performance, availability, and the user experience.

This enhancement is implemented as follows:

1. The default value for `BuildIndexThreads` is changed from 0 to 128. This means that offline ordered index builds are now multithreaded by default.

2. The default value for `TwoPassInitialNodeRestartCopy` is changed from `false` to `true`. This means that an initial node restart first copies all data from a “live” node to one that is starting —without creating any indexes—builds ordered indexes offline, and then again synchronizes its data with the live node, that is, synchronizing twice and building indexes offline between the two synchronizations. This causes an initial node restart to behave more like the normal restart of a node, and reduces the time required for building indexes.

3. A new thread type (`idxbld`) is defined for the `ThreadConfig` configuration parameter, to allow locking of offline index build threads to specific CPUs.

In addition, NDB now distinguishes the thread types that are accessible to “ThreadConfig” by the following two criteria:

1. Whether the thread is an execution thread. Threads of types `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; thread types `io`, `watchdog`, and `idxbld` are not.

2. Whether the allocation of the thread to a given task is permanent or temporary. Currently all thread types except `idxbld` are permanent.

For additional information, see the descriptions of the parameters in the Manual. (Bug #25835748, Bug #26928111)
What is New in NDB Cluster

• **logbuffers table backup process information.** When performing an NDB backup, the ndbinfologbuffers table now displays information regarding buffer usage by the backup process on each data node. This is implemented as rows reflecting two new log types in addition to REDO and DD-UNDO. One of these rows has the log type BACKUP-DATA, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type BACKUP-LOG, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these log_type rows is shown in the logbuffers table for each data node in the cluster. Rows having these two log types are present in the table only while an NDB backup is currently in progress. (Bug #25822988)

• **processes table on Windows.** The process ID of the monitor process used on Windows platforms by RESTART to spawn and restart a mysqld is now shown in the ndbinfoprocesses table as an angel_pid.

• **ODirectSyncFlag.** Added the ODirectSyncFlag configuration parameter for data nodes. When enabled, the data node treats all completed filesystem writes to the redo log as though they had been performed using fsync.

  **Note**

  This parameter has no effect if at least one of the following conditions is true:

  • ODirect is not enabled.
  • InitFragmentLogFiles is set to SPARSE.

  (Bug #25428560)

• **Data node log buffer size control.** Added the --logbuffer-size option for ndbd and ndbmtd, for use in debugging with a large number of log messages. This controls the size of the data node log buffer; the default (32K) is intended for normal operations. (Bug #89679, Bug #27550943)

• **String hashing improvements.** Prior to NDB 8.0, all string hashing was based on first transforming the string into a normalized form, then MD5-hashing the resulting binary image. This could give rise to some performance problems, for the following reasons:

  • The normalized string is always space padded to its full length. For a VARCHAR, this often involved adding more spaces than there were characters in the original string.

  • The string libraries were not optimized for this space padding, and added considerable overhead in some use cases.

  • The padding semantics varied between character sets, some of which were not padded to their full length.

  • The transformed string could become quite large, even without space padding; some Unicode 9.0 collations can transform a single code point into 100 bytes of character data or more.

  • Subsequent MD5 hashing consisted mainly of padding with spaces, and was not particularly efficient, possibly causing additional performance penalties by flush significant portions of the L1 cache.

  Collations provide their own hash functions, which hash the string directly without first creating a normalized string. In addition, for Unicode 9.0 collations, the hashes are computed without padding. NDB now takes advantage of this built-in function whenever hashing a string identified as using a Unicode 9.0 collation.
What is New in NDB Cluster

Since, for other collations there are existing databases which are hash partitioned on the transformed string, NDB continues to employ the previous method for hashing strings that use these, to maintain compatibility. (Bug #89590, Bug #89604, Bug #89609, Bug #27515000, Bug #27523758, Bug #27522732)

(See also.)

• **On-the-fly upgrades of tables using .frm files.** A table created in NDB 7.6 and earlier contains metadata in the form of a compressed .frm file, which is no longer supported in MySQL 8.0. To facilitate online upgrades to NDB 8.0, NDB performs on-the-fly translation of this metadata and writes it into the MySQL Server's data dictionary, which enables the mysqld in NDB Cluster 8.0 to work with the table without preventing subsequent use of the table by a previous version of the NDB software.

  ![Important]
  Once a table's structure has been modified in NDB 8.0, its metadata is stored using the Data Dictionary, and it can no longer be accessed by NDB 7.6 and earlier.

  This enhancement also makes it possible to restore an NDB backup made using an earlier version to a cluster running NDB 8.0 (or later).

• **Schema synchronization of tablespace objects.** When a MySQL Server connects as an SQL node to an NDB cluster, it synchronizes its data dictionary with the information found in NDB dictionary. Previously, the only NDB objects synchronized on connection of a new SQL node were databases and tables; MySQL NDB Cluster 8.0.14 and later also implement schema synchronization of disk data objects including tablespaces and log file groups. Among other benefits, this eliminates the possibility of a mismatch between the MySQL data dictionary and the NDB dictionary following a native backup and restore, in which tablespaces and log file groups were restored to the NDB dictionary, but not to the MySQL Server's data dictionary.

• **Handling of NO_AUTO_CREATE_USER in mysql options file.** An error now is written to the server log when the presence of the NO_AUTO_CREATE_USER value for the sql_mode option in the options file prevents mysqld from starting.

• **Handling of references to nonexistent tablespaces.** It is no longer possible to issue a CREATE TABLE statement that refers to a nonexistent tablespace. Such a statement now fails with an error.

• **RESET MASTER changes.** Because the MySQL Server now executes RESET MASTER with a global read lock, the behavior of this statement when used with NDB Cluster has changed in the following two respects:
  
  • It is no longer guaranteed to be synonchrous; that is, it is now possible that a read coming immediately before RESET MASTER is issued may not be logged until after the binary log has been rotated.
  
  • It now behaves identically, regardless of whether the statement is issued on the same SQL node that is writing the binary log, or on a different SQL node in the same cluster.

  ![Note]
  SHOW BINLOG EVENTS, FLUSH LOGS, and most data definition statements continue, as they did in previous NDB versions, to operate in a synchronous fashion.
• **NDB table extra metadata changes.** In NDB 8.0.14 and later, the extra metadata property of an NDB table is used for storing serialized metadata from the MySQL data dictionary rather than storing the binary representation of the table as in previous versions. (This was a .frm file, no longer used by the MySQL Server—see Chapter 14, *MySQL Data Dictionary*.) As part of the work to support this change, the available size of the table's extra metadata has been increased. This means that NDB tables created in NDB Cluster 8.0.14 and later are not compatible with previous NDB Cluster releases. Tables created in previous releases can be used with NDB 8.0.14 and later, but cannot be opened afterwards by an earlier version.

For more information, see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”.

• **Disk data file distribution.** Beginning with NDB Cluster 8.0.14, NDB uses the MySQL data dictionary to make sure that disk data files and related constructs such as tablespaces and log file groups are correctly distributed between all connected SQL nodes.

• **ndb_restore options.** Beginning with NDB 8.0.16, the `--nodeid` and `--backupid` options are both required when invoking `ndb_restore`.

• **ndb_log_bin system variable.** Beginning with NDB 8.0.16, the default value of the `ndb_log_bin` system variable has changed from `TRUE` to `FALSE`.

### 22.1.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- **Node Configuration Parameters Introduced in NDB 8.0**

- **Node Configuration Parameters Deprecated in NDB 8.0**

- **Node Configuration Parameters Removed in NDB 8.0**

- **MySQL Server Options and Variables Introduced in NDB 8.0**

- **MySQL Server Options and Variables Deprecated in NDB 8.0**

- **MySQL Server Options and Variables Removed in NDB 8.0**

The next few sections contain information about NDB configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 8.0.

#### Node Configuration Parameters Introduced in NDB 8.0

No node configuration parameters have been added to NDB 8.0.

#### Node Configuration Parameters Deprecated in NDB 8.0

No node configuration parameters have been deprecated in NDB 8.0.

#### Node Configuration Parameters Removed in NDB 8.0

No node configuration parameters have been removed from NDB 8.0.

#### MySQL Server Options and Variables Introduced in NDB 8.0

No new system variables, status variables, or options have been added to NDB 8.0.

#### MySQL Server Options and Variables Deprecated in NDB 8.0

No system variables, status variables, or options have been deprecated in NDB 8.0.
MySQL Server Options and Variables Removed in NDB 8.0

No system variables, status variables, or options have been removed from NDB 8.0.

22.1.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both NDB and InnoDB can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see NDB as a possible alternative or upgrade to the default InnoDB storage engine in MySQL 8.0. While NDB and InnoDB share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by NDB 8.0 with InnoDB used in MySQL 8.0. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB back ends.

NDB Cluster 8.0 uses a mysqld based on MySQL 8.0, including support for InnoDB 1.1. While it is possible to use InnoDB tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 8.0 distribution with MySQL Server 8.0, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 22.1.6.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 22.1.6.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 22.1.6.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or NDB Cluster.

See Chapter 16, Alternative Storage Engines, for additional information about MySQL storage engines.

22.1.6.1 Differences Between the NDB and InnoDB Storage Engines

The NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB (MySQL 8.0)</th>
<th>NDB 8.0</th>
</tr>

### 22.1.6.2 NDB and InnoDB Workloads
NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

Table 22.2 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.

22.1.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

Table 22.3 Supported application features according to the storage engine to which each feature is typically better suited

<table>
<thead>
<tr>
<th>Preferred application requirements for InnoDB</th>

22.1.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If we do not plan to fix the problem in NDB Cluster 8.0, we will add it to the list.

See Previous NDB Cluster Issues Resolved in NDB Cluster 7.3 for a list of issues in earlier releases that have been resolved in NDB Cluster 8.0.

Note

Limitations and other issues specific to NDB Cluster Replication are described in Section 22.6.3, "Known Issues in NDB Cluster Replication".

22.1.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'.

- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning Specified key was too long; max key length is 3072 bytes is issued, and a SHOW CREATE TABLE statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.
  - **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM and InnoDB tables only.
However, you can create indexes on VARCHAR columns of NDB tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column NOT NULL, or re-create the index without the USING HASH option.

- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 22.1.7.6, “Unsupported or Missing Features in NDB Cluster”, for additional information.)

- **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table. However, in the case of an NDB table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit AUTO_INCREMENT column unless that column is also declared using the PRIMARY KEY option. Attempting to create a table with an AUTO_INCREMENT column that is not the table's primary key, and using the NDB storage engine, fails with an error.

- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 8.0 is comparable to that provided by InnoDB, subject to the following restrictions:

  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.

  - ON UPDATE CASCADE is not supported when the reference is to the parent table’s primary key.

  This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the NDB kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

  - SET DEFAULT is not supported. (Also not supported by InnoDB.)

  - The NO ACTION keywords are accepted but treated as RESTRICT. (Also the same as with InnoDB.)

  - In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

  For more information, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”, and Section 1.8.3.2, “FOREIGN KEY Constraints”.

- **NDB Cluster and geometry data types.** Geometry data types (WKT and WKB) are supported for NDB tables. However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the ndb_apply_status and ndb_binlog_index tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded
Known Limitations of NDB Cluster

in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any of the --basedir, --log-bin, or --log-bin-index options.

• Creating NDB tables with user-defined partitioning. Support for user-defined partitioning in NDB Cluster is restricted to [LINEAR] KEY partitioning. Using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

Default partitioning scheme. All NDB Cluster tables are by default partitioned by KEY using the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDB storage engine is used instead. For additional discussion of these and related issues, see Section 23.2.5, “KEY Partitioning”.

CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table’s partitioning expression must be part of the primary key.

Exception. If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using PARTITION BY [LINEAR] KEY()), then no explicit primary key is required.

Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group. (See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information about NDB Cluster node groups.

DROP PARTITION not supported. It is not possible to drop partitions from NDB tables using ALTER TABLE ... DROP PARTITION. The other partitioning extensions to ALTER TABLE—ADD PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION—are supported for NDB tables, but use copying and so are not optimized. See Section 23.3.1, “Management of RANGE and LIST Partitions” and Section 13.1.9, “ALTER TABLE Syntax”.

• Row-based replication.
When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of sql_log_bin.

• JSON data type. The MySQL JSON data type is supported for NDB tables in the mysqld supplied with NDB 8.0.

An NDB table can have a maximum of 3 JSON columns.

The NDB API has no special provision for working with JSON data, which it views simply as BLOB data. Handling data as JSON must be performed by the application.

22.1.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.
Known Limitations of NDB Cluster

Memory usage and recovery. Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A DELETE statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing OPTIMIZE TABLE.

A rolling restart of the cluster also frees any memory used by deleted rows. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

- A DROP TABLE or TRUNCATE TABLE operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

Note Recall that TRUNCATE TABLE drops and re-creates the table. See Section 13.1.37, “TRUNCATE TABLE Syntax”.

- Limits imposed by the cluster’s configuration. A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 22.3.3, “NDB Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (DataMemory and IndexMemory, respectively). DataMemory is allocated as 32KB pages. As each DataMemory page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

  See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for more information.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters MaxNoOfConcurrentOperations and MaxNoOfLocalOperations.

Note Bulk loading, TRUNCATE TABLE, and ALTER TABLE are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by MaxNoOfOrderedIndexes, and the maximum number of ordered indexes per table is 16.

  - Node and data object maximums. The following limits apply to numbers of cluster nodes and metadata objects:

    - The maximum number of data nodes is 48.

    A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

    - The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

    - The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.
Known Limitations of NDB Cluster

See Previous NDB Cluster Issues Resolved in NDB Cluster 7.3, for more information.

22.1.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

• **Transaction isolation level.** The NDBCLUSTER storage engine supports only the READ COMMITTED transaction isolation level. (InnoDB, for example, supports READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, and SERIALIZABLE.) You should keep in mind that NDB implements READ COMMITTED on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using SELECT ... LOCK IN SHARE MODE. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

• Increased frequency of lock wait timeout errors, and reduced concurrency
• Increased transaction processing overhead due to reads requiring a commit phase
• Possibility of exhausting the available number of concurrent locks, which is limited by MaxNoOfConcurrentOperations

NDB uses READ COMMITTED for all reads unless a modifier such as LOCK IN SHARE MODE or FOR UPDATE is used. LOCK IN SHARE MODE causes shared row locks to be used; FOR UPDATE causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

See Section 22.5.3.4, “NDB Cluster Backup Troubleshooting”, for information on how NDB Cluster’s implementation of transaction isolation level can affect backup and restoration of NDB databases.

• **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL’s BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:

1. For any SELECT from an NDB Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

2. For any SELECT which uses a unique key lookup to retrieve any columns that use any of the BLOB or TEXT data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

For example, consider the table t defined by the following CREATE TABLE statement:
Known Limitations of NDB Cluster

```
CREATE TABLE t {
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b INT NOT NULL,
    c INT NOT NULL,
    d TEXT,
    INDEX i(b),
    UNIQUE KEY u(c)
} ENGINE = NDB,
```

Either of the following queries on \( t \) causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```
SELECT * FROM t WHERE a = 1;
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

  - **TRUNCATE TABLE** is not transactional when used on \( \text{NDB} \) tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.
  
  - **DELETE FROM** (even with no WHERE clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several DELETE FROM ... LIMIT ... statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use TRUNCATE TABLE instead.
  
  - **LOAD DATA statements.** LOAD DATA is not transactional when used on \( \text{NDB} \) tables.
Important

When executing a `LOAD DATA` statement, the NDB engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an NDB table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (INSERT, DELETE, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(*)` may perform dirty reads, and is not a bug in the NDB storage engine. (See Bug #31321 for more information.)

### 22.1.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 *Temporary failure, distribution changed* and similar temporary errors.

- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 22.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”.

### 22.1.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the NDBCLUSTER storage engine:

- **Database and table names.** When using the NDB storage engine, the maximum allowed length both for database names and for table names is 63 characters. A statement using a database name or table name longer than this limit fails with an appropriate error.

- **Number of database objects.** The maximum number of all NDB database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** The maximum permitted size of any one row is 14000 bytes. Each BLOB or TEXT column contributes $256 + 8 = 264$ bytes to this total.

- **BIT column storage per table.** The maximum combined width for all BIT columns used in a given NDB table is 4096.
• **FIXED column storage.** NDB Cluster 8.0 supports a maximum of 128 TB per fragment of data in FIXED columns.

### 22.1.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

• **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by NDB.

A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089: *Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys, regardless of storage engine:*

```sql
CREATE TABLE t1 (
  c1 INT NOT NULL,
  c2 VARCHAR(100),
  INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

• **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.

• **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

• **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See Section 22.6, “NDB Cluster Replication”, for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 8.0. Do not enable GTIDs when using the NDB storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

Semisynchronous replication is not supported in NDB Cluster.

• **Generated columns.** The NDB storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that NDB uses DataMemory for storage of the generated column as well as IndexMemory for the index. See JSON columns and indirect indexing in NDB Cluster, for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does log not those made to virtual columns. This should not effect NDB Cluster Replication or replication between NDB and other MySQL storage engines.

**Note**

See Section 22.1.7.3, “Limits Relating to Transaction Handling in NDB Cluster”, for more information relating to limitations on transaction handling in NDB.
22.1.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Section 8.9.4, “Index Hints”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

22.1.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the NDB storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster's SQL nodes.

- **Binary logging.**
  NDB Cluster has the following limitations or restrictions with regard to binary logging:

  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.

  - NDB Cluster cannot produce a binary log for tables having BLOB columns but no primary key.

  - Only the following schema operations are logged in a cluster binary log which is not on the mysqld executing the statement:

    - CREATE TABLE
    - ALTER TABLE
    - DROP TABLE
    - CREATE DATABASE/CREATE SCHEMA
    - DROP DATABASE/DROP SCHEMA
    - CREATE TABLESPACE
    - ALTER TABLESPACE
    - DROP TABLESPACE
    - CREATE LOGFILE GROUP
    - ALTER LOGFILE GROUP
    - DROP LOGFILE GROUP
Known Limitations of NDB Cluster

- Schema operations (DDL statements) are rejected while any data node restarts.

- **Number of replicas.** The number of replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting `NoOfReplicas` to a value greater than 2 is possible (to a maximum of 4) but unnecessary to guard against loss of data. In addition, *values greater than 2 for this parameter are not supported in production.*

  See also Section 22.1.7.10, "Limitations Relating to Multiple NDB Cluster Nodes".

### 22.1.7.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)
- Maximum number of data files per tablespace: $2^{16}$ (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.21, "CREATE TABLESPACE Syntax", for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use `DataMemory`. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 22.1.7.10 Limitations Relating to Multiple NDB Cluster Nodes

**Multiple SQL nodes.**

The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

**Multiple management nodes.**

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
• When a management server starts, it first checks for any other management server in the same NDB
  Cluster, and upon successful connection to the other management server uses its configuration data.
  This means that the management server --reload and --initial startup options are ignored unless
  the management server is the only one running. It also means that, when performing a rolling restart of
  an NDB Cluster with multiple management nodes, the management server reads its own configuration
  file if (and only if) it is the only management server running in this NDB Cluster. See Section 22.5.5,
  “Performing a Rolling Restart of an NDB Cluster”, for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of
these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation
that the data node went down but never receives it because another route to that data node remains open.
This can effectively make the cluster inoperable.

Note
It is possible to use multiple network hardware interfaces (such as Ethernet cards)
for a single data node, but these must be bound to the same address. This also
means that it not possible to use more than one [tcp] section per connection in
the config.ini file. See Section 22.3.3.10, “NDB Cluster TCP/IP Connections”,
for more information.

22.2 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster.
Whereas the examples in Section 22.3, “Configuration of NDB Cluster” provide more in-depth information
on a variety of clustering options and configuration, the result of following the guidelines and procedures
outlined here should be a usable NDB Cluster which meets the minimum requirements for availability and
safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of NDB Cluster;
basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and
performing queries.

NDB Cluster also provides the NDB Cluster Auto-Installer, a web-based graphical installer, as part of the
NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB
Cluster on one (for testing) or more host computers. See Section 22.2.1, “The NDB Cluster Auto-Installer”,
for more information.

Assumptions. The following sections make a number of assumptions regarding the cluster’s physical
and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host
computer, and each with a fixed network address on a typical Ethernet network as shown here:

Table 22.4 Network addresses of nodes in example cluster

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
<td>198.51.100.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (ndbd)</td>
<td>198.51.100.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

This setup is also shown in the following diagram:
**Network addressing.** In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system’s equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system’s own host name in the `/etc/hosts` during installation. Consider two machines with the host names ndb1 and ndb2, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines’ `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost

# ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines’ `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb1.cluster ndb1

# ndb2 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb2.cluster ndb2
```

In both instances, ndb1 routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while ndb2 routes `ndb2.cluster` to a loopback address and obtains a
public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

**Caution**

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

**Important**

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL website (see [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html)). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see Section 22.2.2, “Installation of NDB Cluster on Linux”. For information about installation of NDB Cluster on Windows operating systems, see Section 22.2.3, “Installing NDB Cluster on Windows”.

For general information about NDB Cluster hardware, software, and networking requirements, see Section 22.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”.

### 22.2.1 The NDB Cluster Auto-Installer

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.
These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access, using the Paramiko library for executing commands remotely (see Section 22.2.1.1, “NDB Cluster Auto-Installer Requirements”).

22.2.1.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

Supported platforms. The NDB Cluster Auto-Installer is available with NDB 8.0 distributions for recent versions of Linux, Windows, Solaris, and MacOS X. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see https://www.mysql.com/support/supportedplatforms/cluster.html.

Supported web browsers. The web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

Required software—setup host. The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, you can download them from http://python.org/download/.

- **Paramiko 2 or higher.** This is required to communicate with remote hosts using SSH. You can download it from http://www.lag.net/paramiko/. Paramiko may also be available from your system's package manager.

- **Pycrypto version 1.9 or higher.** This cryptography module is required by Paramiko, and can be installed using `pip install cryptography`. If `pip` is not installed, and the module is not available using your system's package manager, you can download it from https://www.dlitz.net/software/pycrypto/.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

The Paramiko and Pycrypto libraries are required only if you intend to deploy NDB Cluster nodes on remote hosts, and are not needed if all nodes are on the same host where the installer is run.

Required software—remote hosts. The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see http://en.wikipedia.org/wiki/Comparison_of_SSH_servers.

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

Authentication and security. Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.
Important

You should never use the system root account for remote access, as this is extremely insecure. In addition, mysqld cannot normally be started by system root. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system root. For more information about this issue, see Section 6.1.5, “How to Run MySQL as a Normal User”.

• HTTPS. Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user’s SSH password is transmitted in clear text that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting ndb_setup.py from the command line with the --use-https (-S) and --cert-file (-c) options.

A sample certificate file cfg.pem is included and is used by default. This file is located in the mcc directory under the installation share directory; on Linux, the full path to the file is normally /usr/share/mysql/mcc.cfg.pem. On Windows systems, this is usually C:\Program Files\MySQL\MySQL Server 8.0\share\mcc\cfg.pem. Letting the default be used means that, for testing purposes, you can simply start the installer with the -S option to use an HTTPS connection between the browser and the back end.

The Auto-Installer saves the configuration file for a given cluster mycluster01 as mycluster01.mcc in the home directory of the user invoking the ndb_setup.py executable. This file is encrypted with a passphrase supplied by the user (using Fernet); because HTTP transmits the passphrase in the clear, it is strongly recommended that you always use an HTTPS connection to access the Auto-Installer on a remote host.

• Certificate-based authentication. The back end ndb_setup.py process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting ndb_setup.py with the --ca-certs-file (-a) option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also Section 22.5.12, “NDB Cluster Security Issues”, which discusses security considerations to take into account when deploying NDB Cluster, as well as Chapter 6, Security, for more general MySQL security information.

22.2.1.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer interface is made up of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster. These pages are listed here, in order:

• Welcome: Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.

• Define Cluster: Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
The NDB Cluster Auto-Installer

- **Define Hosts**: Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes**: Assign one or more processes of a given type or types to each cluster host.
- **Define Parameters**: Set configuration attributes for processes or types of processes.
- **Deploy Configuration**: Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

**NDB Cluster Installer Settings and Help Menus**

These menus are shown on all screens except for the **Welcome** screen. They provide access to installer settings and information. The **Settings** menu is shown here in more detail:

**Figure 22.5 NDB Cluster Auto-Installer Settings menu**

![Settings menu image]

The **Settings** menu has the following entries:

- **Automatically save configuration as cookies**: Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session. This option is enabled by default.

  The SSH password is never saved; if you use one, you must supply it at the beginning of each new session.

- **Show advanced configuration options**: Shows by default advanced configuration parameters where available.

  Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

  You can also toggle the display of advanced parameters for individual processes on the **Define Parameters** screen.

  This option is disabled by default.

- **Automatically get resource information for new hosts**: Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the
suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

This option is enabled by default.

The installer Help menu is shown here:

![Figure 22.6 NDB Cluster Auto-Installer Help menu](image)

The Help menu provides several options, described in the following list:

- **Contents**: Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.

- **Current page**: Open the built-in user guide to the section describing the page currently displayed in the installer.

- **About**: open a dialog displaying the installer name and the version number of the NDB Cluster distribution with which it was supplied.

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets.

In addition, the names of most NDB configuration parameters are linked to their descriptions in the online documentation. The documentation is displayed in a separate browser window.

The next section discusses starting the Auto-Installer. The sections immediately following it describe in greater detail the purpose and function of each of these pages in the order listed previously.

**Starting the NDB Cluster Auto-Installer**

The Auto-Installer is provided together with the NDB Cluster software. Separate RPM and .deb packages containing only the Auto-Installer are also available for many Linux distributions. (See Section 22.2, “NDB Cluster Installation”.)

The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.

**User and privileges**

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should not run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.
The NDB Cluster Auto-Installer

`ndb_setup.py` is found in the **bin** within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 8.0\bin` on a Windows system. This can vary according to where the NDB Cluster software is installed on your system, and the installation method.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, this batch file accepts the same options as `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster **bin** directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```shell
shell> ndb_setup.py
Running out of install dir: /usr/local/mysql/bin
Starting web server on port 8081
URL is https://localhost:8081/welcome.html
deathkey=627876
Press CTRL+C to stop web server.
(Alternatively you can navigate to https://localhost:8081/welcome.html to start it)
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster **bin** directory in a file browser (such as Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer’s **Welcome screen** should open in the system’s default web browser. If not, you should be able to open the page `http://localhost:8081/welcome.html` or `https://localhost:8081/welcome.html` manually in the browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying HTTPS for connections, or a different port for the Auto-Installer’s included web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) If you plan to use the Auto-Installer from a remote host, you should start using the `-S` option. For information about this and other advanced startup options for the NDB Cluster Auto-Installer, see Section 22.4.26, “`ndb_setup.py` — Start browser-based Auto-Installer for NDB Cluster”.

**NDB Cluster Auto-Installer Welcome Screen**

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked. The first time the Auto-Installer is run (or if for some other reason there are no existing configurations), this screen appears as shown here:
In this case, the only choice of cluster listed is for configuration of a new cluster, and both the View Cfg and Continue buttons are inactive.

To create a new configuration, enter and confirm a passphrase in the text boxes provided. When this has been done, you can click Continue to proceed to the Define Cluster screen where you can assign a name to the new cluster.

If you have previously created one or more clusters with the Auto-Installer, they are listed by name. This example shows an existing cluster named mycluster-1:
To view the configuration for and work with a given cluster, select the radiobutton next to its name in the list, then enter and confirm the passphrase that was used to create it. When you have done this correctly, you can click View Cfg to view and edit this cluster's configuration.

**NDB Cluster Auto-Installer Define Cluster Screen**

The Define Cluster screen is appears following the Welcome screen, and is used for setting general properties of the cluster. The layout of the Define Cluster screen is shown here:
This screen and subsequent screens also include Settings and Help menus which are described later in this section; see NDB Cluster Installer Settings and Help Menus.

The Define Cluster screen allows you to set three sorts of properties for the cluster: cluster properties, SSH properties, and installation properties.

Cluster properties that can be set on this screen are listed here:

- **Cluster name**: A name that identifies the cluster; in this example, this is `mycluster-1`. The name is set on the previous screen and cannot be changed here.

- **Host list**: A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the credentials supplied as SSH properties.

- **Application type**: Choose one of the following:
  1. **Simple testing**: Minimal resource usage for small-scale testing. This the default. Not intended for production environments.
  2. **Web**: Maximize performance for the given hardware.
  3. **Real-time**: Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.

- **Write load**: Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low**: The expected load includes fewer than 100 write transactions per second.
  2. **Medium**: The expected load includes 100 to 1000 write transactions per second; this is the default.
3. **High**: The expected load includes more than 1000 write transactions per second.

SSH properties are described in the following list:

- **Key-Based SSH**: Check this box to use key-enabled login to the remote host. If checked, the key user and passphrase must also be supplied; otherwise, a user and password for a remote login account are needed.

- **User**: Name of user with remote login access.

- **Password**: Password for remote user.

- **Key user**: Name of the user for whom the key is valid, if not the same as the login user.

- **Key passphrase**: Passphrase for the key, if required.

- **Key file**: Path to the key file. The default is `~/.ssh/id_rsa`.

The SSH properties set on this page apply to all hosts in the cluster. They can be overridden for a given host by editing that host's properties on the Define Hosts screen.

Two installation properties can also be set on this screen:

- **Install MySQL Cluster**: This setting determines the source from which the Auto-Installer installs NDB Cluster software, if any, on the cluster hosts. Possible values and their effects are listed here:
  1. **DOCKER**: Try to install the MySQL Cluster Docker image from [https://hub.docker.com/r/mysql/mysql-cluster/](https://hub.docker.com/r/mysql/mysql-cluster/) on each host
  2. **REPO**: Try to install the NDB Cluster software from the MySQL Repositories on each host
  3. **BOTH**: Try to install either the Docker image or the software from the repository on each host, giving preference to the repository
  4. **NONE**: Do not install the NDB Cluster software on the hosts; this is the default

- **Open FW Ports**: Check this checkbox to have the installer attempt to open ports required by NDB Cluster processes on all hosts.

The next figure shows the Define Cluster page with settings for a small test cluster with all nodes running on *localhost*.
After making the desired settings, you can save them to the configuration file and proceed to the Define Hosts screen by clicking the Save & Next button.

If you exit the installer without saving, no changes are made to the configuration file.

**NDB Cluster Auto-Installer Define Hosts Screen**

The Define Hosts screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:
Properties shown include the following:

- **Host**: Name or IP address of this host
- **Res.info**: Shows **OK** if the installer was able to retrieve requested resource information from this host
- **Platform**: Operating system or platform
- **Memory (MB)**: Amount of RAM on this host
- **Cores**: Number of CPU cores available on this host
- **MySQL Cluster install directory**: Path to directory where the NDB Cluster software is installed on this host; defaults to `/usr/local/bin`
- **MySQL Cluster data directory**: Path to directory used for data by NDB Cluster processes on this host; defaults to `/var/lib/mysql-cluster`
- **DiskFree**: Free disk space in bytes

For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

This screen also provides an extended view for each host that includes the following properties:

- **FDQN**: This host’s fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP**: The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details**: Detailed operating system name and version information.
- **Open FW**: If this checkbox is enabled, the installer attempts to open ports in the host’s firewall needed by cluster processes.
- **REPO URL**: URL for MySQL NDB Cluster repository
The NDB Cluster Auto-Installer

- **DOCKER URL**: URL for MySQL NDB Cluster Docker images; for NDB 8.0, this is `mysql/mysql-cluster:8.0`.

- **Install**: If this checkbox is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host.

The extended view is shown here:

**Figure 22.12 NDB Cluster Define Hosts screen, extended host info view**

All cells in the display are editable, with the exceptions of those in the **Host**, **Res.info**, and **FQDN** columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

**Adding and Removing Hosts**

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:
This dialog includes the following fields:
The NDB Cluster Auto-Installer

- **Host name**: A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.

- **Host internal IP (VPN)**: If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.

- **Key-based auth**: If checked, enables key-based authentication. You can enter any additional needed information in the **User**, **Passphrase**, and **Key file** fields.

- **Ordinary login**: If accessing this host using a password-based login, enter the appropriate information in the **User** and **Password** fields.

- **Open FW ports**: Selecting this checkbox allows the installer try opening any ports needed by cluster processes in this host's firewall.

- **Configure installation**: Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. **When you remove a host, any process which was configured for that host is also removed.**

**Warning**

**Remove selected host(s)** acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the **Define Cluster screen** are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host’s platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:
When more than one host is selected, any edited values are applied to all selected hosts.

Once you have entered all desired host information, you can use the Save & Next button to save the information to the cluster's configuration file and proceed to the Define Processes screen, where you can set up NDB Cluster processes on one or more hosts.

**NDB Cluster Auto-Installer Define Processes Screen**

The Define Processes screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:
This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the Define Hosts screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.

- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.

- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtd`.

- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.

- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See MySQL NDB Cluster API Developer Guide, for more information.

For more information about process (node) types, see Section 22.1.1, “NDB Cluster Core Concepts”.

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node may be assigned to a single host, but this is not required. Instead, you can assign it to the special Any host entry which the tree also contains in addition to any
other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this Any host entry.*

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

![Figure 22.16 NDB Cluster Auto-Installer Add Process Dialog](image)

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, select that process in the tree and use the **Del process** button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (*ndbmt*.) to a single-threaded data node (*ndbd*), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.*

**NDB Cluster Auto-Installer Define Parameters Screen**

Like the **Define Processes** screen, this screen includes a process tree; the **Define Parameters** process tree is organized by process or node type, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. An information panel displays information regarding the item currently selected. The **Define Attributes** screen is shown here:
The checkbox labelled **Show advanced configuration**, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking **Show advanced configuration options** under **Settings** (see NDB Cluster Installer Settings and Help Menus).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:
Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X. The X button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

**NDB Cluster Auto-Installer Deploy Configuration Screen**

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied

- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, deploy the cluster as presently configured

- Start and stop the cluster

The **Deploy Configuration** screen is shown here:
Like the Define Parameters screen, this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (CONNECTED), starting (STARTING), running (STARTED), stopping (STOPPING), or disconnected (NO_CONTACT). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster**: Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster**: Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is displayed when the deployment has completed, as shown here:
• **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

![Cluster Startup Process with Progress Bar](image)

The process status icons next to the items shown in the process tree also update with the status of each process.

A confirmation dialog is shown when the startup process has completed, as shown here:
• **Stop cluster**: After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

A confirmation dialog indicates when the shutdown process is complete:
The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

### 22.2.2 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 22.2.3, “Installing NDB Cluster on Windows”.

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmtd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a `.tar.gz` archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 22.2.4, “Initial Configuration of NDB Cluster”.

#### 22.2.2.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 8.0 release, this is `mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.

If you require a custom binary, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.
Installation of NDB Cluster on Linux

**Note**
After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 22.2.4, “Initial Configuration of NDB Cluster”).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```shell
   shell> groupadd mysql
   shell> useradd -g mysql -s /bin/false mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

   ```shell
   shell> cd /var/tmp
   shell> tar -C /usr/local -xzvf mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64.tar.gz
   shell> ln -s /usr/local/mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

   ```shell
   shell> cd mysql
   shell> mysqld --initialize
   ```

   This generates a random password for the MySQL root account. If you do not want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review Section 2.10.1, “Initializing the Data Directory”, for additional information before performing this step. See also Section 4.4.2, “mysql_secure_installation — Improve MySQL Installation Security”.

4. Set the necessary permissions for the MySQL server and data directories:

   ```shell
   shell> chown -R root .
   shell> chown -R mysql data
   shell> chgrp -R mysql .
   ```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

   ```shell
   shell> cp support-files/mysql.server /etc/rc.d/init.d/
   ```
Installation of NDB Cluster on Linux

shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is /etc/init.d.)

Here we use Red Hat’s `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo, su root, or your system’s equivalent for temporarily assuming the system administrator account’s privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

    shell> cd /var/tmp
    shell> tar -zxvf mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64.tar.gz
    shell> cd mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64
    shell> cp bin/ndbd /usr/local/bin/ndbd
    shell> cp bin/ndbmtd /usr/local/bin/ndbmtd

    (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

    shell> cd /usr/local/bin
    shell> chmod +x ndb*

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

**Note**

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 22.2.4, “Initial Configuration of NDB Cluster”.)

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgm` and `ndb_mgmd` on the management node host:

shell> cd /usr/local/bin
shell> chmod +x ndb*
1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.15-linux-glibc2.12-x86_64
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In Section 22.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

### 22.2.2.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster 8.0 node using RPM packages supplied by Oracle. For information about RPMs for previous versions of NDB Cluster, see Installation using old-style RPMs (NDB 7.5.3 and earlier).

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the Yum Repository, for instructions and additional information.
- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See Installing MySQL NDB Cluster Using the SLES Repository, for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-8.0.15-1.el7.x86_64.rpm
mysql-cluster-license-component-ver-rev.distro.arch.rpm
```

- `license` indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.
Possible values for *component*, with descriptions, can be found in the following table:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto-installer</td>
<td>NDB Cluster Auto Installer program; see Section 22.2.1, “The NDB Cluster Auto-Installer”, for usage</td>
</tr>
<tr>
<td>client</td>
<td>MySQL and NDB client programs; includes mysql client, ndb_mgm client, and other client tools</td>
</tr>
<tr>
<td>common</td>
<td>Character set and error message information needed by the MySQL server</td>
</tr>
<tr>
<td>data-node</td>
<td>ndbd and ndbmtd data node binaries</td>
</tr>
<tr>

</tr>
<tr>
<td>server-minimal</td>
<td>Minimal installation of the MySQL server for NDB and related tools</td>
</tr>
<tr>
<td>test</td>
<td>mysqltest, other MySQL test programs, and support files</td>
</tr>
</tbody>
</table>

A single bundle (.tar file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```
You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- **Management node**: `management-server`
- **Data node**: `data-node`
- **SQL node**: `server` and `common`

In addition, the **client** RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in 8.0.x format, shown as `8.0.15` in the examples. `rev` provides the RPM revision number in major.minor format. In the examples shown in this section, we use `1.1` for this value.

The **distro** (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `el6` (Oracle Linux 6, Red Hat Enterprise Linux 6), `el7` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`el7`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as `8.0.15`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the **data-node** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-data-node-8.0.15-1.el7.x86_64.rpm
```

This installs the `ndbd` and `ndbmtd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the **server** and **common** RPMs to each machine to be used for hosting an NDB Cluster SQL node (**server** requires **common**). Install the **server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-server-8.0.15-1.el7.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with NDB storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.
Installation of NDB Cluster on Linux

Important
You must use the versions of these RPMs released for NDB Cluster; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

shell> rpm -Uhv mysql-cluster-community-client-8.0.15-1.el7.x86_64.rpm

This installs the mysql client and other MySQL client programs, such as mysqladmin and mysqldump, to /usr/bin.

Management nodes. To install the NDB Cluster management server, it is necessary only to use the management-server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the management-server RPM downloaded from the MySQL website):

shell> rpm -Uhv mysql-cluster-commercial-management-server-8.0.15-1.el7.x86_64.rpm

This RPM installs the management server binary ndb_mgmd in the /usr/sbin directory. While this is the only program actually required for running a management node, it is also a good idea to have the ndb_mgm NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as ndb_desc and ndb_config, by installing the client RPM as described previously.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see Section 22.2.4, “Initial Configuration of NDB Cluster”, for the relevant information.

It is very important that all of the Cluster RPMs to be installed have the same version number. The architecture designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

Data nodes. On a computer that is to host a cluster data node it is necessary to install only the server RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.15-1.sles11.i386.rpm

Although this installs all NDB Cluster binaries, only the program ndbd or ndbmtd (both in /usr/sbin) is actually needed to run an NDB Cluster data node.

SQL nodes. On each machine to be used for hosting a cluster SQL node, install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.15-1.sles11.i386.rpm

This installs the MySQL server binary (mysqld) with NDB storage engine support in the /usr/sbin directory, as well as all needed MySQL Server support files. It also installs the mysql.server and
Installation of NDB Cluster on Linux

The installation process for an NDB Cluster on Linux involves installing database startup scripts and managing the MySQL server. Here are the steps:

### Installation of NDB Cluster on Linux

**MySQL startup scripts** (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the **client RPM**, as shown here:

```shell
rpm -Uhv MySQL-Cluster-client-gpl-8.0.15-1.sles11.i386.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the **server RPM**. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the server RPM downloaded from the MySQL website):

```shell
rpm -Uhv MySQL-Cluster-server-gpl-8.0.15-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The server RPM also installs `ndb_mgm`, the NDB management client.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle. See Section 22.2.4, “Initial Configuration of NDB Cluster”, for information about required post-installation configuration.

### 22.2.2.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See Installing MySQL NDB Cluster Using the APT Repository, for instructions and additional information.

Oracle provides `.deb` installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (8 or 9), and `arch` is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 8.0.15 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-8.0.15-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate `.deb` file, you can untar it, and then install it from the command line using `dpkg`, like this:

```shell
dpkg -i mysql-cluster-gpl-8.0.15-debian9-i686.deb
```

You can also remove it using `dpkg` as shown here:

```shell
dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as **GDebi** for the Gnome desktop.
Installation of NDB Cluster on Linux

The .deb file installs NDB Cluster under /opt/mysql/server-version/, where version is the 2-part release series version for the included MySQL server. For NDB 8.0, this is always 5.7. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”), with the exception that startup scripts and configuration files are found in support-files instead of share. All NDB Cluster executables, such as ndb_mgm, ndbd, and ndb_mgmd, are placed in the bin directory.

22.2.2.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, “Installing MySQL from Source”. For information about compiling NDB Cluster on Windows platforms, see Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at https://dev.mysql.com/downloads/. The archived source file should have a name similar to mysql-8.0.15.tar.gz. You can also obtain MySQL development sources from launchpad.net.

Note

In previous versions, building of NDB Cluster from standard MySQL Server sources was not supported. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case—both products are now built from the same sources.

The WITH_NDBCLUSTER option for CMake causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes mysqld to be compiled with NDB storage engine support. This option (or one of its aliases WITH_NDBCLUSTER_STORAGE_ENGINE and WITH_PLUGIN_NDBCLUSTER) is required when building NDB Cluster.

Important

The WITH_NDB_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH_NDB_JAVA=OFF. Use WITH_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

After you have run make && make install (or your system’s equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

Management nodes. When building from source and running the default make install, the management server and management client binaries (ndb_mgmd and ndb_mgm) can be found in /usr/local/mysql/bin. Only ndb_mgmd is required to be present on a management node host; however, it is also a good idea to have ndb_mgm present on the same host machine. Neither of these executables requires a specific location on the host machine’s file system.

Data nodes. The only executable required on a data node host is the data node binary ndbd or ndbmtd. (mysqld, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory /usr/local/mysql/bin. For installing on multiple data node hosts, only ndbd or ndbmtd need be copied to the other host machine or machines. (This
assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with NDB storage engine support causes ndbmtd to be built automatically; make install places the ndbmtd binary in the installation bin directory along with mysqld, ndbd, and ndb_mgm.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using make install as the system root user), mysqld is placed in /usr/local/mysql/bin. Follow the steps given in Section 2.9, “Installing MySQL from Source” to make mysqld ready for use. If you want to run multiple SQL nodes, you can use a copy of the same mysqld executable and its associated support files on several machines. The easiest way to do this is to copy the entire /usr/local/mysql directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault PREFIX option, you must adjust the directory accordingly.

In Section 22.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

### 22.2.3 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 8.0 binaries for Windows can be obtained from https://dev.mysql.com/downloads/cluster/. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 22.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

#### 22.2.3.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 22.2, “NDB Cluster Installation”), as shown in the following table:

**Table 22.6 Network addresses of nodes in example cluster**

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>

</tbody>
</table>

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (mysqld.exe). You should also have the MySQL client (mysql.exe) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (ndb_mgmd.exe); each data node requires the data node daemon (ndbd.exe or ndbmtd.exe). For this example, we refer to ndbd.exe as the data node executable, but you can install ndbmtd.exe, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (ndb_mgm.exe) on the
management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

**Note**

As with other Windows programs, NDB Cluster executables are named with the .exe file extension. However, it is not necessary to include the .exe extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as mysqld, mysql, ndb_mgmd, and so on. You should understand that, whether we refer (for example) to mysqld or mysqld.exe, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's no-install binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from https://dev.mysql.com/downloads/cluster/. This archive has a filename of the mysql-cluster-gpl-ver-winarch.zip, where ver is the NDB storage engine version (such as 8.0.15), and arch is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 8.0.15 archive for 64-bit Windows systems is named mysql-cluster-gpl-8.0.15-win64.zip.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory C:\Documents and Settings\username\My Documents\Downloads on the computer having the IP address 198.51.100.20, where username is the name of the current user. (You can obtain this name using ECHO %USERNAME% on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the Administrators group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter C:\, which causes the Extraction Wizard to extract the archive to the directory C:\mysql-cluster-gpl-ver-winarch. Rename this directory to C:\mysql.

It is possible to install the NDB Cluster binaries to directories other than C:\mysql\bin; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than C:\mysql or C:\Program Files\MySQL\MySQL Server 8.0, or if the SQL node's data directory is in a location other than C:\mysql\data or C:\Program Files\MySQL\MySQL Server 8.0\data, extra configuration options must be used on the command line or added to the my.ini or my.cnf file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options --ndbcluster and --ndb-connectstring. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster # run NDB storage engine
ndb-connectstring=198.51.100.10 # location of management server
```
Installing NDB Cluster on Windows

You can add other options used by this MySQL Server if desired (see Section 2.3.5.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories C:\mysql, C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the --ndb-connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10  # location of management server
```

Save this file as C:\mysql\my.ini on the data node host. Create another text file containing the same information and save it on as C:\mysql\my.ini on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node's C:\mysql directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program ndb_mgmd.exe. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program ndb_mgm.exe on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the no-install archive; this should be the directory C:\mysql\bin on the SQL node host. Create the directory C:\mysql\bin on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by ndb_mgmd.exe:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```
   [mysql_cluster]
   # Options for management node process
   config-file=C:\mysql\bin\config.ini
   ```

   Save this file as the text file C:\mysql\bin\my.ini.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (HostName configuration parameter). It is also advisable to include the following additional information:

   - The IP address or hostname of any SQL nodes
Installing NDB Cluster on Windows

- The data memory and index memory allocated to each data node (\texttt{DataMemory} and \texttt{IndexMemory} configuration parameters)
- The number of replicas, using the \texttt{NoOfReplicas} configuration parameter (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”)
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the \texttt{DataDir} configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2                      # Number of replicas
DataDir=C:/mysql/cluster-data       # Directory for each data node's data files
# Forward slashes used in directory path, rather than backslashes. This is correct;
# see Important note in text
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
# For DataMemory and IndexMemory, we have used the default values. Since the "world" database takes up
# only about 500KB, this should be more than enough for this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10              # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30            # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=198.51.100.40            # Hostname or IP address

[mysqld]
# SQL node options:
HostName=198.51.100.20            # Hostname or IP address
```

Save this file as the text file \texttt{C:/mysql/bin/config.ini}.

\textbf{Important}

A single backslash character (\textbackslash) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\textbackslash\textbackslash), or replace the backslash with a forward slash character (/). For example, the following line from the [\texttt{ndb_mgmd}] section of an NDB Cluster \texttt{config.ini} file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
```
Installing NDB Cluster on Windows

DataDir=C:/mysql/bin/cluster-logs  # Forward slashes

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

22.2.3.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build NDB Cluster 8.0, use the MySQL Server 8.0 sources, which you can obtain from https://dev.mysql.com/downloads/.

  Formerly, NDB Cluster used its own source code. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case, and both products are now built from the same source.

- You must configure the build using the WITH_NDBCLUSTER option in addition to any other build options you wish to use with CMake. WITH_NDBCLUSTER_STORAGE_ENGINE and WITH_PLUGIN_NDBCLUSTER are supported as aliases for WITH_NDBCLUSTER, and work in exactly the same way.

**Important**

The WITH_NDB_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH_NDB_JAVA=OFF. (Bug #12379735)

Use WITH_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; Section 2.9.2, “Installing MySQL Using a Standard Source Distribution” provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the bin directory of the resulting archive, which is equivalent to the no-install archive, and which can be installed and configured in the same manner. For more information, see Section 22.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

22.2.3.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

   ```cmd
   C:\mysql\bin> ndb_mgmd
   2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
   ```
The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which ndb_mgmd.exe is running; doing so kills the management node process. (See Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”, where we show how to install and run NDB Cluster processes as Windows services.)

The required -f option tells the management node where to find the global configuration file (config.ini). The long form of this option is --config-file.

Important

An NDB Cluster management node caches the configuration data that it reads from config.ini; once it has created a configuration cache, it ignores the config.ini file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read config.ini after you have corrected any errors in it. You can do this by starting ndb_mgmd.exe with the --reload or --initial option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's my.ini file.

For additional information about options which can be used with ndb_mgmd, see Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, as well as Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills ndbd.exe. (For more information, see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client ndb_mgm.exe, which should be in C:\mysql\bin on the management node host. (Do not try to re-use the console window where ndb_mgm.exe is running by typing CTRL+C, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt ndb_mgm> appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by
entering ALL STATUS at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-8.0.15-ndb-8.0.15)
Node 3: starting (Last completed phase 3) (mysql-8.0.15-ndb-8.0.15)

Node 2: starting (Last completed phase 4) (mysql-8.0.15-ndb-8.0.15)
Node 3: starting (Last completed phase 4) (mysql-8.0.15-ndb-8.0.15)

Node 2: Started (version 8.0.15)
Node 3: Started (version 8.0.15)
```

**Note**

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the ndb_mgm client. For more information, see Section 22.5.2, “Commands in the NDB Cluster Management Client”.

The output produced by ALL STATUS is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave ndb_mgm.exe running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is C:\mysql\bin).

Start the SQL node by invoking mysqld.exe from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The --console option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it without the --console option, so that logging is performed normally.)

In the console window where the management client (ndb_mgm.exe) is running on the management node host, enter the SHOW command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
  id=2    @198.51.100.30  (Version: 8.0.15-ndb-8.0.15, Nodegroup: 0, *)
  id=3    @198.51.100.40  (Version: 8.0.15-ndb-8.0.15, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
  id=1    @198.51.100.10  (Version: 8.0.15-ndb-8.0.15)
```
Installing NDB Cluster on Windows

[mysqld(API)] 1 node(s)
id=4 198.51.100.20 (Version: 8.0.15-ndb-8.0.15)

You can also verify that the SQL node is connected to the NDB Cluster in the mysql client (mysql.exe) using the SHOW ENGINE NDB STATUS statement.

You should now be ready to work with database objects and data using NDB Cluster's NDBCLUSTER storage engine. See Section 22.2.6, “NDB Cluster Example with Tables and Data”, for more information and examples.

You can also install ndb_mgmd.exe, ndbd.exe, and ndbmtd.exe as Windows services. For information on how to do this, see Section 22.2.3.4, "Installing NDB Cluster Processes as Windows Services".

### 22.2.3.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate SC START and SC STOP commands, or using the Windows graphical Services utility. NET START and NET STOP commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke ndb_mgmd.exe from the command line on the machine hosting the management node, using the --install option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
   as "C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"
Service successfully installed.
```

**Important**

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error *The system cannot find the file specified.*

The --install option must be used first, ahead of any other options that might be specified for ndb_mgmd.exe. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of ndb_mgmd.exe --help, you can specify the location using the --config-file option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

**Note**

If using NET commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
```
Installing NDB Cluster on Windows

The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than ndb_mgmd, append it to the --install option, as shown in this example:

C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server' as "C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"
Service successfully installed.

Now you should be able to start or stop the service using the name you have specified, like this:

C:\> SC START mgmd1
C:\> SC STOP mgmd1

To remove the management node service, use SC DELETE service_name:

C:\> SC DELETE mgmd1

Alternatively, invoke ndb_mgmd.exe with the --remove option, as shown here:

C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.

If you installed the service using a service name other than the default, pass the service name as the value of the ndb_mgmd.exe --remove option, like this:

C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the --install option for ndbd.exe (or ndbmtd.exe), as shown here:

C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as "C:\mysql\bin\ndbd.exe" "--service=ndbd"
Service successfully installed.

Now you can start or stop the data node as shown in the following example:

C:\> SC START ndbd
C:\> SC STOP ndbd

To remove the data node service, use SC DELETE service_name:

C:\> SC DELETE ndbd
Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```plaintext
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```plaintext
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as "C:\mysql\bin\ndbd.exe" "--service=dnode1"
Service successfully installed.
```

```plaintext
C:\> SC START dnode1
C:\> SC STOP dnode1
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

```plaintext
C:\> SC DELETE dnode1
```

Alternatively, you can pass the service name as the value of the `ndbd.exe --remove` option, as shown here:

```plaintext
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `SC START`, `SC STOP`, and `SC DELETE` (or `mysqld --remove`). .NET commands can also be used to start or stop a service. For additional information, see Section 22.3.5.8, "Starting MySQL as a Windows Service".

### 22.2.4 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see Section 22.2.1, "The NDB Cluster Auto-Installer".

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.
**Initial Configuration of NDB Cluster**

**Configuring the data nodes and SQL nodes.** The my.cnf file needed for the data nodes is fairly simple. The configuration file should be located in the /etc directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

Note
---

We show vi being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, my.cnf should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster              # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

**Important**
---

Once you have started a mysqld process with the ndbcluster and ndb-connectstring parameters in the [mysqld] and [mysql_cluster] sections of the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the config.ini file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage

[ndbd_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of MGM node
DataDir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
HostName=198.51.100.30          # Hostname or IP address
NodeId=2                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files
```
Initial Startup of NDB Cluster

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 22.3.3, “NDB Cluster Configuration Files”, and Section 22.3, “Configuration of NDB Cluster”. For configuration of NDB Cluster as relates to making backups, see Section 22.5.3.3, “Configuration for NDB Cluster Backups”.

---

**Note**

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

---

### 22.2.5 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

   shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini

   The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 22.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", for details.)

   For additional options which can be used with `ndb_mgmd`, see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run this command to start the `ndbd` process:

   shell> ndbd

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

---

The world database can be downloaded from [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html).

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 22.2.5, “Initial Startup of NDB Cluster”. 

---

Note

The world database can be downloaded from [https://dev.mysql.com/doc/index-other.html](https://dev.mysql.com/doc/index-other.html).
If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @198.51.100.30  (Version: 8.0.15-ndb-8.0.15, Nodegroup: 0, *)
id=3    @198.51.100.40  (Version: 8.0.15-ndb-8.0.15, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @198.51.100.10  (Version: 8.0.15-ndb-8.0.15)

[mysqld(API)]   1 node(s)
id=4    @198.51.100.20  (Version: 8.0.15-ndb-8.0.15)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

**Note**

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 22.2.6, “NDB Cluster Example with Tables and Data”, for a brief discussion.

### 22.2.6 NDB Cluster Example with Tables and Data

**Note**

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

  ```
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

  ```
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)
If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`) ) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

```sql
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
```

(remaining INSERT statements omitted)

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (  
  `ID` int(11) NOT NULL auto_increment,  
  `Name` char(35) NOT NULL default '',  
  `CountryCode` char(3) NOT NULL default '',  
  `District` char(20) NOT NULL default '',  
  `Population` int(11) NOT NULL default '0',  
  PRIMARY KEY  (`ID`) ) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

```sql
INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
```

(remaining INSERT statements omitted)

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).
To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.15-ndb-8.0.15
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see Section 2.10.4, "Securing the Initial MySQL Account".

It is worth taking into account that NDB Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) affects only applications that access the SQL node, not interaction between nodes. See Section 22.5.12.2, "NDB Cluster and MySQL Privileges", for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bombay</td>
<td>10500000</td>
</tr>
<tr>
<td>Seoul</td>
<td>9981619</td>
</tr>
<tr>
<td>São Paulo</td>
<td>9968485</td>
</tr>
<tr>
<td>Shanghai</td>
<td>9696300</td>
</tr>
<tr>
<td>Jakarta</td>
<td>9604900</td>
</tr>
</tbody>
</table>
+-----------+------------+
5 rows in set (0.34 sec)
```

```
mysql> \q
Bye
```

```
shell>
```
Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```php
<?php
  # connect to SQL node:
  $link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
                FROM City
                ORDER BY Population DESC
                LIMIT 5";

  if( $result = $link->query($query) )
  {
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>
             <td align="center">%s</td><td>%d</td>
           </tr>
        \n", $row->Name, $row->Population);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.
22.2.7 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (198.51.100.10 in our example setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40):

  ```
  shell> ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (198.51.100.20):

  ```
  shell> mysqld_safe &
  ```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (198.51.100.10 in our example setup), execute the following command:

  ```
  C:\> SC START ndb_mgmd
  ```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40), execute the following command:

  ```
  C:\> SC START ndbd
  ```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Section 22.2.3.3, “Initial Startup of NDB Cluster on Windows”).

- On the SQL node host (198.51.100.20), execute the following command:

  ```
  C:\> SC START mysql
  ```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both),
which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

### 22.2.8 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 8.0 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring an NDB Cluster prior to attempting an upgrade or downgrade. See Section 22.3, “Configuration of NDB Cluster”.

**Important**

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software. See Section 2.11, “Upgrading MySQL”.

**Known Issues.** The following issues are known to occur when upgrading to or between NDB 8.0 releases:

- Online downgrades from NDB 8.0.14 to previous releases are not supported. Tables created in NDB 8.0.14 are not backwards compatible with previous releases. This is due to a change in usage of the extra metadata property implemented by NDB tables to provide full support for the MySQL data dictionary.

For more information, see NDB table extra metadata changes. See also Chapter 14, MySQL Data Dictionary.

### 22.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server’s my.cnf configuration file, or start the server with the --ndbcluster option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on localhost. However, should you need to specify that its location is elsewhere, this can be done in my.cnf, or with the mysql client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about --ndbcluster and other mysqld options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

You can use also the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see The NDB Cluster Auto-Installer (NDB 7.5).

For general information about installing NDB Cluster, see Section 22.2, “NDB Cluster Installation”.
22.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as /var/lib/mysql-cluster, by executing the following command as the system root user:

shell> mkdir /var/lib/mysql-cluster

In this directory, create a file named config.ini that contains the following information. Substitute appropriate values for HostName and DataDir as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
/tcp default

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the ndb_mgmd management server. By default, it attempts to read the config.ini file in its current working directory, so change location into the directory where the file is located and then invoke ndb_mgmd:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running ndbd:

```
shell> ndbd
```

For command-line options which can be used when starting ndbd, see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

By default, ndbd looks for the management server at localhost on port 1186.
Quick Test Setup of NDB Cluster

Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the ndb_mgmd and ndbd servers explicitly. (Normally, these will be found in /usr/local/mysql/bin.)

Finally, change location to the MySQL data directory (usually /var/lib/mysql or /usr/local/mysql/data), and make sure that the my.cnf file contains the option necessary to enable the NDB storage engine:

```javascript
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```shell
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice mysql ended, check the server's .err file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDBCLUSTER storage engine is enabled:

```shell
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.17
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SHOW ENGINES\G
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an NDBCLUSTER table:

```shell
shell> mysql
mysql> USE test;
Database changed
mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)
mysql> SHOW CREATE TABLE ctest \G
```

1 row in set (0.00 sec)
Overview of NDB Cluster Configuration Parameters, Options, and Variables

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)] 1 node(s)
id=2  @127.0.0.1  (Version: 8.0.15-ndb-8.0.15, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1  @127.0.0.1  (Version: 8.0.15-ndb-8.0.15)

[mysqld(API)] 3 node(s)
id=3  @127.0.0.1  (Version: 8.0.15-ndb-8.0.15)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

### 22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

#### Considerations when restarting nodes.

For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

---

**Important**

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the...
cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes. In addition, it is generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note
4294967039 often appears as a maximum value in these tables. This value is defined in the NDBCLUSTER sources as MAX_INT_RNIL and is equal to 0xFFFFFFFFF, or $2^{32} - 2^8 - 1$.

22.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the [ndbd] or [ndbd default] sections of a config.ini file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

These parameters also apply to ndbmtd, the multithreaded version of ndbd. For more information, see Section 22.4.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)".

- **Arbitration**: How arbitration should be performed to avoid split-brain issues in the event of node failure.
- **ArbitrationTimeout**: Maximum time (milliseconds) database partition waits for arbitration signal
- **BackupDataBufferSize**: Default size of databuffer for a backup (in bytes)
- **BackupDataDir**: Path to where to store backups. Note that the string '/BACKUP' is always appended to this setting, so that the *effective* default is FileSystemPath/BACKUP.
- **BackupDiskWriteSpeedPct**: Sets the percentage of the data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting a backup.
- **BackupLogBufferSize**: Default size of log buffer for a backup (in bytes)
- **BackupMaxWriteSize**: Maximum size of file system writes made by backup (in bytes)
- **BackupMemory**: Total memory allocated for backups per node (in bytes)
- **BackupReportFrequency**: Frequency of backup status reports during backup in seconds
- **BackupWriteSize**: Default size of file system writes made by backup (in bytes)
- **BatchSizePerLocalScan**: Used to calculate the number of lock records for scan with hold lock
- **BuildIndexThreads**: Number of threads to use for building ordered indexes during a system or node restart. Also applies when running ndb_restore --rebuild-indexes. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- **CompressedBackup**: Use zlib to compress backups as they are written
- **CompressedLCP**: Write compressed LCPs using zlib
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ConnectCheckIntervalDelay**: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.

- **CrashOnCorruptedTuple**: When enabled, forces node to shut down whenever it detects a corrupted tuple.

- **DataDir**: Data directory for this node

- **DataMemory**: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.

- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840. Intended primarily for upgrades and downgrades within NDB 7.2.

- **DictTrace**: Enable DBDICT debugging; for NDB development

- **DiskIOThreadPool**: Number of unbound threads for file access (currently only for Disk Data); known as IOThreadPool before MySQL Cluster NDB 6.4.3.

- **Diskless**: Run without using the disk

- **DiskPageBufferEntries**: Number of 32K page entries to allocate in DiskPageBufferMemory. Very large disk transactions may require increasing this value.

- **DiskPageBufferMemory**: Number of bytes on each data node allocated for the disk page buffer cache

- **DiskSyncSize**: Amount of data written to file before a synch is forced

- **EnablePartialLcp**: Enable partial LCP (true); if this disabled (false), all LCPs write full checkpoints.

- **EnableRedoControl**: Enable adaptive checkpointing speed for controlling redo log usage

- **EventLogBufferSize**: Size of circular buffer for NDB log events within data nodes.

- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- **FileSystemPath**: Path to directory where the data node stores its data (directory must exist)

- **FileSystemPathDataFiles**: Path to directory where the data node stores its Disk Data files. The default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, the value of DataDir is used.

- **FileSystemPathDD**: Path to directory where the data node stores its Disk Data and undo files. The default value is FileSystemPath, if set; otherwise, the value of DataDir is used.

- **FileSystemPathUndoFiles**: Path to directory where the data node stores its undo files for Disk Data. The default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, the value of DataDir is used.

- **FragmentLogFileSize**: Size of each redo log file

- **HeartbeatIntervalDbApi**: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats)

- **HeartbeatIntervalDbDb**: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats
• **HeartbeatOrder**: Sets the order in which data nodes check each others' heartbeats for determining whether a given node is still active and connected to the cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.

• **HostName**: Host name or IP address for this data node.

• **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.

• **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.

• **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates

• **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.

• **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.

• **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. The value is scaled down by IndexStatTriggerScale.

• **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by the base 2 logarithm of the index size, for a large index. Set to 0 to disable scaling.

• **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for a given index. 0 means no delay.

• **InitFragmentLogFiles**: Initialize fragment logfiles (sparse/full)

• **InitialLogFileGroup**: Describes a log file group that is created during an initial start. See documentation for format.

• **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file)

• **InitialTablespace**: Describes a tablespace that is created during an initial start. See documentation for format.

• **InsertRecoveryWork**: Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use

• **LateAlloc**: Allocate memory after the connection to the management server has been established.

• **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.

• **LockExecuteThreadToCPU**: A comma-delimited list of CPU IDs

• **LockMaintThreadsToCPU**: CPU ID indicating which CPU runs the maintenance threads

• **LockPagesInMainMemory**: Previously: If set to true/1, then NDB Cluster data is not swapped out to disk. In MySQL 5.0.36/5.1.15 and later: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation

• **LogLevelCheckpoint**: Log level of local and global checkpoint information printed to stdout

• **LogLevelCongestion**: Level of congestion information printed to stdout

• **LogLevelConnection**: Level of node connect/disconnect information printed to stdout

• **LogLevelError**: Transporter, heartbeat errors printed to stdout
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **LogLevelInfo**: Heartbeat and log information printed to stdout
- **LogLevelNodeRestart**: Level of node restart and node failure information printed to stdout
- **LogLevelShutdown**: Level of node shutdown information printed to stdout
- **LogLevelStartup**: Level of node startup information printed to stdout
- **LogLevelStatistic**: Level of transaction, operation, and transporter information printed to stdout
- **LongMessageBuffer**: Number of bytes allocated on each data node for internal long messages
- **MaxAllocate**: Maximum size of allocation to use when allocating memory for tables
- **MaxBufferedEpochs**: Allowed number of epochs that a subscribing node can lag behind (unprocessed epochs). Exceeding will cause lagging subscribers to be disconnected.
- **MaxBufferedEpochBytes**: Total number of bytes allocated for buffering epochs.
- **MaxDiskWriteSpeed**: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- **MaxDiskWriteSpeedOtherNodeRestart**: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- **MaxDiskWriteSpeedOwnRestart**: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
- **MaxFKBuildBatchSize**: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- **MaxDMLOperationsPerTransaction**: Limit size of a transaction; aborts the transaction if it requires more than this many DML operations. Set to 0 to disable.
- **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- **MaxNoOfAttributes**: Suggests a total number of attributes stored in database (sum over all tables)
- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node
- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator
- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on the data node
- **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations
- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, the total number of transactions that can be executed concurrently is this value times the number of data nodes in the cluster.
- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node
- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node
- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node
- **MaxNoOfOpenFiles**: Maximum number of files open per data node. (One thread is created per file)
- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in the system
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain
- **MaxNoOfSubscribers**: Maximum number of subscribers (default 0 = MaxNoOfTables * 2)
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables)
- **MaxNoOfTables**: Suggests a total number of NDB tables stored in the database
- **MaxNoOfTriggers**: Total number of triggers that can be defined in the system
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in the system
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- **MemReportFrequency**: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: The percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which the data node belongs; used only during initial start of cluster.
- **NodeId**: Number uniquely identifying the data node among all nodes in the cluster.
- **NoOfDiskPagesToDiskDuringRestartACC**: Disk checkpoint speed
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to the data node
- **NoOfReplicas**: Number of copies of all data in database; recommended value is 2 (default). Values greater than 2 are not supported in production.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O_DIRECT file reads and writes when possible.
- **ODirectSyncFlag**: O_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RecoveryWork**: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **RedoBuffer**: Number bytes on each data node allocated for writing redo logs
- **RedoOverCommitCounter**: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- **RedoOverCommitLimit**: Each time that flushing the current redo buffer takes longer than this many seconds, the number of times that this has happened is compared to RedoOverCommitCounter.
- **RestartOnErrorInsert**: Control the type of restart caused by inserting an error (when StopOnError is enabled)
- **SchedulerExecutionTimer**: Number of microseconds to execute in scheduler before sending
- **SchedulerResponsiveness**: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput
- **SchedulerSpinTimer**: Number of microseconds to execute in scheduler before sleeping
- **ServerPort**: Port used to set up transporter for incoming connections from API nodes
- **SharedGlobalMemory**: Total number of bytes on each data node allocated for any use
- **StartFailRetryDelay**: Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- **StartFailureTimeout**: Milliseconds to wait before terminating. (0=Wait forever)
- **StartNoNodeGroupTimeout**: Time to wait for nodes without a nodegroup before trying to start (0=forever)
- **StartPartialTimeout**: Milliseconds to wait before trying to start without all nodes. (0=Wait forever)
- **StartPartitionedTimeout**: Milliseconds to wait before trying to start partitioned. (0=Wait forever)
- **StartupStatusReportFrequency**: Frequency of status reports during startup
- **StopOnError**: When set to 0, the data node automatically restarts and recovers following node failures
- **StringMemory**: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes)
- **TcpBind_INADDR_ANY**: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections)
- **TimeBetweenEpochs**: Time between epochs (synchronization used for replication)
- **TimeBetweenEpochsTimeout**: Timeout for time between epochs. Exceeding will cause node shutdown.
- **TimeBetweenGlobalCheckpoints**: Time between doing group commit of transactions to disk
- **TimeBetweenGlobalCheckpointsTimeout**: Minimum timeout for group commit of transactions to disk
- **TimeBetweenInactiveTransactionAbortCheck**: Time between checks for inactive transactions
- **TimeBetweenLocalCheckpoints**: Time between taking snapshots of the database (expressed in base-2 logarithm of bytes)
- **TimeBetweenWatchDogCheck**: Time between execution checks inside a data node
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **TimeBetweenWatchDogCheckInitial**: Time between execution checks inside a data node (early start phases when memory is allocated)

- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.

- **TransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node

- **TransactionDeadlockDetectionTimeout**: Time transaction can spend executing within a data node. This is the time that the transaction coordinator waits for each data node participating in the transaction to execute a request. If the data node takes more than this amount of time, the transaction is aborted.

- **TransactionInactiveTimeout**: Milliseconds that the application waits before executing another part of the transaction. This is the time the transaction coordinator waits for the application to execute or send another part (query, statement) of the transaction. If the application takes too much time, then the transaction is aborted. Timeout = 0 means that the application never times out.

- **TwoPassInitialNodeRestartCopy**: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.

- **UndoDataBuffer**: Number of bytes on each data node allocated for writing data undo logs

- **UndoIndexBuffer**: Number of bytes on each data node allocated for writing index undo logs

The following parameters are specific to `ndbmtd`:

- **MaxNoOfExecutionThreads**: For ndbmtd only, specify maximum number of execution threads

- **NoOfFragmentLogParts**: Number of redo log file groups belonging to this data node; value must be an even multiple of 4.

- **ThreadConfig**: Used for configuration of multithreaded data nodes (ndbmtd). Default is an empty string; see documentation for syntax and other information.

### 22.3.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this long before voting (milliseconds)

- **ArbitrationRank**: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2

- **DataDir**: Data directory for this node

- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER

- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- **HeartbeatIntervalMgmdMgmd**: Time between management node-to-management node heartbeats; the connection between management node is considered lost after 3 missed heartbeats.

- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for management nodes; see manual for allowed values

- **HostName**: Host name or IP address for this management node.
• **Id**: Number identifying the management node (Id). Now deprecated; use NodeId instead.

• **LogDestination**: Where to send log messages: console, system log, or specified log file

• **NodeId**: Number uniquely identifying the management node among all nodes in the cluster.

• **PortNumber**: Port number to send commands to and fetch configuration from management server

• **PortNumberStats**: Port number used to get statistical information from a management server

• **TotalSendBufferMemory**: Total memory to use for all transporter send buffers

• **wan**: Use WAN TCP setting as default

---

**Note**

After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 22.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the [mysqld] and [api] sections of a config.ini file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

• **ApiVerbose**: Enable NDB API debugging; for NDB development

• **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this many milliseconds before voting

• **ArbitrationRank**: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2

• **AutoReconnect**: Specifies whether an API node should reconnect fully when disconnected from the cluster

• **BatchByteSize**: The default batch size in bytes

• **BatchSize**: The default batch size in number of records

• **ConnectBackoffMaxTime**: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.

• **ConnectionMap**: Specifies which data nodes to connect

• **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840. Intended primarily for upgrades and downgrades within NDB 7.2.

• **DefaultOperationRedoProblemAction**: How operations are handled in the event that RedoOverCommitCounter is exceeded
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for API nodes; see manual for allowed values
- **HostName**: Host name or IP address for this SQL or API node.
- **Id**: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.
- **MaxScanBatchSize**: The maximum collective batch size for one scan
- **NodeId**: Number uniquely identifying the SQL node or API node among all nodes in the cluster.
- **StartConnectBackoffMaxTime**: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers
- **wan**: Use WAN TCP setting as default

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster; for information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 22.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the [computer], [tcp], [shm], and [sci] sections of a config.ini file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, or Section 22.3.3.13, “SCI Transport Connections in NDB Cluster”, as appropriate.

The following parameters apply to the config.ini file’s [computer] section:

- **HostName**: Host name or IP address of this computer.
- **Id**: A unique identifier for this computer.

The following parameters apply to the config.ini file’s [tcp] section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors
- **Group**: Used for group proximity; smaller value is interpreted as being closer
- **NodeId1**: ID of node (data node, API node, or management node) on one side of the connection
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **NodeId2**: ID of node (data node, API node, or management node) on one side of the connection
- **NodeIdServer**: Set server side of TCP connection
- **OverloadLimit**: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors
- **Proxy**:
- **ReceiveBufferMemory**: Bytes of buffer for signals received by this node
- **SendBufferMemory**: Bytes of TCP buffer for signals sent from this node
- **SendSignalId**: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- **TCP_MAXSEG_SIZE**: Value used for TCP_MAXSEG
- **TCP_RCV_BUF_SIZE**: Value used for SO_RCVBUF
- **TCP_SND_BUF_SIZE**: Value used for SO_SNDBUF
- **TcpBind_INADDR_ANY**: Bind InAddrAny instead of host name for server part of connection

The following parameters apply to the `config.ini` file’s `[shm]` section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors
- **Group**:
  - **NodeId1**: ID of node (data node, API node, or management node) on one side of the connection
  - **NodeId2**: ID of node (data node, API node, or management node) on one side of the connection
  - **NodeIdServer**: Set server side of SHM connection
  - **OverloadLimit**: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
  - **PreSendChecksum**: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors
- **SendBufferMemory**: Bytes in shared memory buffer for signals sent from this node
- **SendSignalId**: Sends ID in each signal. Used in trace files.
- **ShmKey**: A shared memory key; when set to 1, this is calculated by NDB
- **ShmSpinTime**: When receiving, number of microseconds to spin before sleeping
- **ShmSize**: Size of shared memory segment
- **Signum**: Signal number to be used for signalling
- **UseShm**: Use shared memory connections between nodes

The following parameters apply to the `config.ini` file’s `[sci]` section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Group:**
  - **Host1SciId0:** SCI-node ID for adapter 0 on Host1 (a computer can have two adapters)
  - **Host1SciId1:** SCI-node ID for adapter 1 on Host1 (a computer can have two adapters)
  - **Host2SciId0:** SCI-node ID for adapter 0 on Host2 (a computer can have two adapters)
  - **Host2SciId1:** SCI-node ID for adapter 1 on Host2 (a computer can have two adapters)
  - **NodeId1:** ID of node (data node, API node, or management node) on one side of the connection
  - **NodeId2:** ID of node (data node, API node, or management node) on one side of the connection
  - **NodeIdServer:**

- **OverloadLimit:** When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- **SendLimit:** Transporter send buffer contents are sent when this number of bytes is buffered
- **SendSignalId:** Sends ID in each signal. Used in trace files.
- **SharedBufferSize:** Size of shared memory segment

**22.3.2.5 NDB Cluster mysqld Option and Variable Reference**

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see Section 5.1.4, “Server Option, System Variable, and Status Variable Reference”.

- **Com_show_ndb_status:** Count of SHOW NDB STATUS statements
- **Handler_discover:** Number of times that tables have been discovered
- **ndb-batch-size:** Size (in bytes) to use for NDB transaction batches
- **ndb-blob-read-batch-bytes:** Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- **ndb-blob-write-batch-bytes:** Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- **ndb-cluster-connection-pool:** Number of connections to the cluster used by MySQL
- **ndb-cluster-connection-pool-nodeids:** Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool
- **ndb-connectstring:** Point to the management server that distributes the cluster configuration
- **ndb-default-column-format:** Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.
- **ndb-deferred-constraints:** Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- **ndb-distribution:** Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb-log-apply-status**: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.

- **ndb-log-empty-epochs**: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- **ndb-log-empty-update**: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- **ndb-log-exclusive-reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts

- **ndb-log-orig**: Log originating server id and epoch in mysql.ndb_binlog_index table

- **ndb-log-transaction-id**: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.

- **ndb-mgmd-host**: Set the host (and port, if desired) for connecting to management server

- **ndb-nodeid**: NDB Cluster node ID for this MySQL server

- **ndb-rev-thread-activation-threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)

- **ndb-rev-thread-cpu-mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- **ndb-transid-mysql-connection-map**: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name

- **ndb-wait-connected**: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections

- **ndb-wait-setup**: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete

- **ndb-allow-copying-alter-table**: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables

- **Ndb_api_bytes_received_count**: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node)

- **Ndb_api_bytes_received_count_session**: Amount of data (in bytes) received from the data nodes in this client session

- **Ndb_api_bytes_received_count_slave**: Amount of data (in bytes) received from the data nodes by this slave

- **Ndb_api_bytes_sent_count**: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node)

- **Ndb_api_bytes_sent_count_slave**: Amount of data (in bytes) sent to the data nodes by this slave

- **Ndb_api_event_bytes_count_injector**: Number of bytes of events received by the NDB binary log injector thread

- **Ndb_api_event_data_count_injector**: Number of row change events received by the NDB binary log injector thread
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_event_nondata_count_injector**: Number of events received, other than row change events, by the NDB binary log injector thread
- **Ndb_api_pk_op_count**: Number of operations based on or using primary keys by this MySQL Server (SQL node)
- **Ndb_api_pk_op_count_session**: Number of operations based on or using primary keys in this client session
- **Ndb_api_pk_op_count_slave**: Number of operations based on or using primary keys by this slave
- **Ndb_api_pruned_scan_count**: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node)
- **Ndb_api_pruned_scan_count_session**: Number of scans that have been pruned to a single partition in this client session
- **Ndb_api_range_scan_count_slave**: Number of range scans that have been started by this slave
- **Ndb_api_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node)
- **Ndb_api_read_row_count_session**: Total number of rows that have been read in this client session
- **Ndb_api_scan_batch_count_slave**: Number of batches of rows received by this slave
- **Ndb_api_table_scan_count**: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node)
- **Ndb_api_table_scan_count_session**: Number of table scans that have been started, including scans of internal tables, in this client session
- **Ndb_api_trans_abort_count**: Number of transactions aborted by this MySQL Server (SQL node)
- **Ndb_api_trans_abort_count_session**: Number of transactions aborted in this client session
- **Ndb_api_trans_abort_count_slave**: Number of transactions aborted by this slave
- **Ndb_api_trans_close_count**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node)
- **Ndb_api_trans_close_count_session**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session
- **Ndb_api_trans_close_count_slave**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave
- **Ndb_api_trans_commit_count**: Number of transactions committed by this MySQL Server (SQL node)
- **Ndb_api_trans_commit_count_session**: Number of transactions committed in this client session
- **Ndb_api_trans_commit_count_slave**: Number of transactions committed by this slave
- **Ndb_api_trans_local_read_row_count_slave**: Total number of rows that have been read by this slave
- **Ndb_api_trans_start_count**: Number of transactions started by this MySQL Server (SQL node)
- **Ndb_api_trans_start_count_session**: Number of transactions started in this client session
- **Ndb_api_trans_start_count_slave**: Number of transactions started by this slave
- **Ndb_api_uk_op_count**: Number of operations based on or using unique keys by this MySQL Server (SQL node)
- **Ndb_api_uk_op_count_slave**: Number of operations based on or using unique keys by this slave
- **Ndb_api_wait_exec_complete_count**: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node)
- **Ndb_api_wait_exec_complete_count_session**: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session
- **Ndb_api_wait_exec_complete_count_slave**: Number of times thread has been blocked while waiting for execution of an operation to complete by this slave
- **Ndb_api_wait_meta_request_count**: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node)
- **Ndb_api_wait_meta_request_count_session**: Number of times thread has been blocked waiting for a metadata-based signal in this client session
- **Ndb_api_wait_nanos_count**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node)
- **Ndb_api_wait_nanos_count_session**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session
- **Ndb_api_wait_nanos_count_slave**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave
- **Ndb_api_wait_scan_result_count**: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node)
- **Ndb_api_wait_scan_result_count_session**: Number of times thread has been blocked while waiting for a scan-based signal in this client session
- **Ndb_api_wait_scan_result_count_slave**: Number of times thread has been blocked while waiting for a scan-based signal by this slave
- **ndb_autoincrement_prefetch_sz**: NDB auto-increment prefetch size
- **ndb_cache_check_time**: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache
- **ndb_clear_apply_status**: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default
- **Ndb_cluster_node_id**: If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster
- **Ndb_config_from_host**: The host name or IP address of the Cluster management server Formerly Ndb_connected_host
- **Ndb_config_from_port**: The port for connecting to Cluster management server. Formerly Ndb_connected_port
- **Ndb_conflict_fn_epoch_trans**: Number of rows that have been found in conflict by the NDB $EPOCH_TRANS() conflict detection function
- **Ndb\_conflict\_fn\_max**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied.

- **Ndb\_conflict\_fn\_old**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied.

- **Ndb\_conflict\_trans\_detect\_iter\_count**: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb\_conflict\_trans\_commit\_count.

- **Ndb\_conflict\_trans\_row\_reject\_count**: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb\_conflict\_trans\_row\_conflict\_count and any rows included in or dependent on conflicting transactions.

- **ndb\_data\_node\_neighbour**: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.

- **ndb\_default\_column\_format**: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.

- **ndb\_deferred\_constraints**: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- **ndb\_distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- **ndb\_eventbuffer\_free\_percent**: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb\_eventbuffer\_max\_alloc.

- **ndb\_eventbuffer\_max\_alloc**: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).

- **ndb\_extra\_logging**: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log.

- **ndb\_force\_send**: Forces sending of buffers to NDB immediately, without waiting for other threads.

- **ndb\_fully\_replicated**: Whether new NDB tables are fully replicated.

- **ndb\_index\_stat\_enable**: Use NDB index statistics in query optimization.

- **ndb\_index\_stat\_option**: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces.

- **ndb\_join\_pushdown**: Enables pushing down of joins to data nodes.

- **ndb\_log\_apply\_status**: Whether or not a MySQL server acting as a slave logs mysql.ndb\_apply\_status updates received from its immediate master in its own binary log, using its own server ID.

- **ndb\_log\_bin**: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.

- **ndb\_log\_binlog\_index**: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_log_empty_epochs**: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_empty_update**: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_exclusive_reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- **ndb_log_orig**: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.

- **ndb_log_transaction_id**: Whether NDB transaction IDs are written into the binary log (Read-only.)

- **ndb-log-update-minimal**: Log updates in a minimal format.

- **ndb_log_updated_only**: Log complete rows (ON) or updates only (OFF)

- **Ndb_number_of_data_nodes**: If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

- **ndb_optimization_delay**: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.

- **ndb_optimized_node_selection**: Determines how an SQL node chooses a cluster data node to use as transaction coordinator.

- **Ndb_pushed_queries_defined**: Number of joins that API nodes have attempted to push down to the data nodes.

- **Ndb_pushed_queries_executed**: Number of joins successfully pushed down and executed on the data nodes.

- **ndb_read_backup**: Enable read from any replica.

- **ndb_recv_thread_activation_threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads).

- **ndb_recv_thread_cpu_mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- **ndb_report_thresh_binlog_epoch_slip**: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message.

- **ndb_report_thresh_binlog_mem_usage**: This is a threshold on the percentage of free memory remaining before reporting binary log status.

- **Ndb_scan_count**: The total number of scans executed by NDB since the cluster was last started.

- **ndb_show_foreign_key_mock_tables**: Show the mock tables used to support foreign_key_checks=0.

- **ndb_slave_conflict_role**: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.

- **Ndb_slave_max_replicated_epoch**: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.
NDB Cluster Configuration Files

- **Ndb_system_name**: Configured cluster system name; empty if server not connected to NDB
- **ndb_table_no_logging**: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.
- **ndb_table_temporary**: NDB tables are not persistent on disk: no schema files are created and the tables are not logged
- **ndb_use_exact_count**: Use exact row count when planning queries
- **ndb_use_transactions**: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query
- **ndb_version**: Shows build and NDB engine version as an integer
- **ndb_version_string**: Shows build information including NDB engine version in ndb-x.y.z format
- **ndbcluster**: Enable NDB Cluster (if this version of MySQL supports it) Disabled by \(--skip-ndbcluster\)
- **ndbinfo_database**: The name used for the NDB information database; read only
- **ndbinfo_max_bytes**: Used for debugging only
- **ndbinfo_max_rows**: Used for debugging only
- **ndbinfo_offline**: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views
- **ndbinfo_show_hidden**: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.
- **ndbinfo_table_prefix**: The prefix to use for naming ndbinfo internal base tables
- **ndbinfo_version**: The version of the ndbinfo engine; read only
- **server-id-bits**: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.
- **server_id_bits**: The effective value of server_id if the server was started with the \(--server-id-bits\) option set to a nondefault value
- **slave_allow_batching**: Turns update batching on and off for a replication slave
- **transaction_allow_batching**: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

### 22.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- **my.cnf**: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- **config.ini**: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. **config.ini** contains a description of each node involved in the cluster.
NDB Cluster Configuration Files

includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the config.ini File.

Caching of configuration data. NDB uses stateful configuration. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When --initial is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.** The --reload option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.** This disables --config-cache (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the config.ini file instead.

- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named mysql-cluster in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is /usr/local/mysql-cluster.) This can be overridden at runtime by starting the management server with the --configdir option. Configuration cache files are binary files named according to the pattern ndb_node_id_config.bin.seq_id, where node_id is the management server's node ID in the cluster, and seq_id is a cache identifier. Cache files are numbered sequentially using seq_id, in the order in which they are created. The management server uses the latest cache file as determined by the seq_id.

**Note**

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher seq_id. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the --configdir, --config-cache, --initial, and --reload options for the NDB Cluster management server, see Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”.

22.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update my.cnf as shown in the following example. You may also specify these parameters on the command line when invoking the executables.
Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```sql
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.0)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini

(For more information on connection strings, see Section 22.3.3.3, "NDB Cluster Connection Strings".)

# my.cnf
# example additions to my.cnf for NDB Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```sql
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

You may also use a separate `mysql_cluster` section in the cluster `my.cnf` file for settings to be read and used by all executables:

For additional NDB variables that can be set in the `my.cnf` file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd`
NDB Cluster Configuration Files

on the command line. This option has no default value, and is ignored if ndb_mgmd uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in config.ini. To create a default value section, simply add the word default to the section name. For example, an [ndbd] section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an [ndbd default] section that contains a DataMemory line to specify the data memory size.

Note

In some older releases of NDB Cluster, there was no default value for NoOfReplicas, which always had to be specified explicitly in the [ndbd default] section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```ini
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndbd_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]

[mysqld]
Hostname= mysqld_5.mysql.com
```

Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See Section 22.3.3.2, "Recommended Starting Configuration for NDB Cluster", which provides a more complete example starting configuration.
Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `ndbd` sections defining these nodes.

**Note**
Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

### Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- **[computer]**: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but may be used as a convenience when setting up a large cluster. See Section 22.3.3.4, “Defining Computers in an NDB Cluster”, for more information.

- **[ndbd]**: Defines a cluster data node (`ndbd` process). See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for details.

- **[mysqld]**: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **[mgm]** or **[ndb_mgmd]**: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

- **[tcp]**: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

- **[shm]**: Defines shared-memory connections between nodes. In MySQL 8.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.

- **[sci]**: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.0.

You can define `default` values for each section. NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

### 22.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
NDB Cluster Configuration Files

- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster’s data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following config.ini file is a recommended starting point for configuring a cluster running NDB Cluster 8.0:

```ini
# TCP PARAMETERS
[tcp default]
SendBufferMemory = 2M
ReceiveBufferMemory = 2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir = path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.
[ndb_mgmd]
HostName = management-server-A-hostname
# NodeId = management-server-A-nodeid

[ndb_mgmd]
HostName = management-server-B-hostname
# NodeId = management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS
[ndbd default]
NoOfReplicas = 2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory = 1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
```
# which can severely degrade cluster performance.

```plaintext
DataMemory=3072M
IndexMemory=384M
```

The values provided for DataMemory and IndexMemory assume 4 GB RAM per data node. However, for best results, you should first calculate the memory that would be used based on the data you actually plan to store (you may find the `ndb_size.pl` utility helpful in estimating this), then allow an extra 20% over the calculated values. Naturally, you should ensure that each data node host has at least as much physical memory as the sum of these two values.

```plaintext
ODirect=1
```

Enabling this parameter causes NDBCLUSTER to try using O_DIRECT writes for local checkpoints and redo logs; this can reduce load on CPUs. We recommend doing so when using NDB Cluster on systems running Linux kernel 2.6 or later.

```plaintext
NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000
SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
```

Setting these parameters allows you to take advantage of real-time scheduling of NDB threads to achieve increased throughput when using ndbd. They are not needed when using ndbmtd; in particular, you should not set `RealTimeScheduler` for ndbmtd data nodes.

```plaintext
TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M
```

```plaintext
CompressedLCP=1
CompressedBackup=1
```

Enabling CompressedLCP and CompressedBackup causes, respectively, local checkpoint files and backup files to be compressed, which can result in a space savings of up to 50% over noncompressed LCPs and backups.

```plaintext
MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256
```

```
[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
```

On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER threads to specific CPUs.

```
[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
```

You must have an [ndbd] section for every data node in the cluster; each of these sections must include a HostName. Each section may optionally include a NodeId for convenience, but in most cases, it is sufficient to allow the cluster to allocate node IDs dynamically. If you do specify the node ID for a data node, it must be in the range 1
NDB Cluster Configuration Files

# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]

# HostName = sql-node-A-hostname
# NodeId = sql-node-A-nodeid

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes
must always be started with the --ndbcluster and --ndb-connectstring options, either on the
command line or in my.cnf. In addition, set the following options for all mysqld processes in the cluster,
unless your setup requires otherwise:

• --ndb-use-exact-count=0
• --ndb-index-stat-enable=0
• --ndb-force-send=1
• --engine-condition-pushdown=1

22.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (ndb_mgmd), each node that is part of an NDB
Cluster requires a connection string that points to the management server's location. This connection
string is used in establishing a connection to the management server as well as in performing other tasks
depending on the node's role in the cluster. The syntax for a connection string is as follows:

[nodeId=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
  host_name[1:port_number]

node_id is an integer greater than or equal to 1 which identifies a node in config.ini.host_name is
a string representing a valid Internet host name or IP address. port_number is an integer referring to a
TCP/IP port number.
localhost:1186 is used as the default connection string value if none is provided. If port_num is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```plaintext
[nodeid=node_id, ]
[bind-address=host-definition, ]
host-definition[; bind-address=host-definition]
host-definition[; bind-address=host-definition]
[,] ...
```

If a single bind address is used in the connection string prior to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use 198.51.100.242 regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified following a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses localhost to connect to the management server running on the host named poseidon and 198.51.100.242 to connect to the management server running on the host named perch.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, localhost is used for connecting to the management server running on host poseidon; since 198.51.100.242 is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts perch and orca:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost, perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.
• For backward compatibility, two other options are available, using the same syntax:

1. Set the \texttt{NDB\_CONNECTSTRING} environment variable to contain the connection string.

2. Write the connection string for each executable into a text file named \texttt{Ndb.cfg} and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the \texttt{my.cnf} file for each executable.

### 22.3.3.4 Defining Computers in an NDB Cluster

The \texttt{[computer]} section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

• \texttt{Id}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

\begin{center}
\textbf{Important}
\end{center}

The computer ID is \textit{not} the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use NodeId in place of \texttt{Id} in the \texttt{[computer]} section of the \texttt{config.ini} file.

• \texttt{HostName}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This is the computer's hostname or IP address.

### 22.3.3.5 Defining an NDB Cluster Management Server
The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

**Note**

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- **Id**

  Table 22.9 This table provides type and value information for the `Id` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- **NodeId**

  Table 22.10 This table provides type and value information for the `NodeId` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.
Note
Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

NodeId is the preferred parameter name to use when identifying management nodes. Although the older Id continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- **ExecuteOnComputer**

Table 22.11 This table provides type and value information for the ExecuteOnComputer management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers defined in a [computer] section of the config.ini file.

Important
This parameter is deprecated, and is subject to removal in a future release. Use the HostName parameter instead.

- **PortNumber**

Table 22.12 This table provides type and value information for the PortNumber management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>1186</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This is the port number on which the management server listens for configuration requests and management commands.

- **HostName**
### Table 22.13 This table provides type and value information for the HostName management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- **LocationDomainId**

### Table 22.14 This table provides type and value information for the LocationDomainId management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns a management node to a specific **availability domain** (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

**LocationDomainId** takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- **LogDestination**
Table 22.15 This table provides type and value information for the LogDestination management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>{CONSOLE</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies where to send cluster logging information. There are three options in this regard—CONSOLE, SYSLOG, and FILE—with FILE being the default:

- **CONSOLE** outputs the log to `stdout`:

```
CONSOLE
```

- **SYSLOG** sends the log to a syslog facility, possible values being one of `auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6, or local7`.

```
SYSLOG:facility=syslog
```

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:
  - **filename**: The name of the log file.
  - **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
  - **maxfiles**: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

```
FILE:filename=ndb_nodeid_cluster.log,maxsize=1000000,maxfiles=6, where node_id is the ID of the node.
```

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**
Table 22.16 This table provides type and value information for the ArbitrationRank management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- **ArbitrationDelay**

Table 22.17 This table provides type and value information for the ArbitrationDelay management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

Table 22.18 This table provides type and value information for the DataDir management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon’s process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **PortNumberStats**

Table 22.19 This table provides type and value information for the `PortNumberStats` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- **Wan**

Table 22.20 This table provides type and value information for the `wan` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **HeartbeatThreadPriority**

Table 22.21 This table provides type and value information for the `HeartbeatThreadPriority` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
policy: {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of FIFO (first in, first out) or RR (round robin). The policy value is followed optionally by the priority (an integer).

- **TotalSendBufferMemory**

Table 22.22 This table provides type and value information for the TotalSendBufferMemory management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- **HeartbeatIntervalMgmdMgmd**

Table 22.23 This table provides type and value information for the HeartbeatIntervalMgmdMgmd management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the
connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 22.3.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster’s data nodes.

-[ndbd] and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to `ndbmtd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (`ndbmtd`). See also Section 22.4.3, “`ndbmtd` — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `NodeId`
Table 22.24 This table provides type and value information for the NodeId data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 48</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

NodeId is the only supported parameter name to use when identifying data nodes.

• **ExecuteOnComputer**

Table 22.25 This table provides type and value information for the ExecuteOnComputer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers defined in a [computer] section.

⚠️ **Important**

This parameter is deprecated, and is subject to removal in a future release. Use the HostName parameter instead.

• **HostName**

Table 22.26 This table provides type and value information for the HostName data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>localhost</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than localhost, either this parameter or ExecuteOnComputer is required.

• **ServerPort**
Table 22.27 This table provides type and value information for the ServerPort data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [ndbd] section or (if you need to do this for multiple data nodes) the [ndbd default] section of the config.ini file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

### Note

Connections from data nodes to management nodes is done using the ndb_mgmd management port (the management server's PortNumber) so outgoing connections to that port from any data nodes should always be permitted.

- **TcpBind_INADDR_ANY**

  Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- **NodeGroup**

Table 22.28 This table provides type and value information for the NodeGroup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65536</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the [ndbd default] section of the config.ini file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.
The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 22.5.15.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

- **LocationDomainId**

Table 22.29 This table provides type and value information for the `LocationDomainId` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns a data node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters’ WAN support without any further manual intervention.

- The transporter’s group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- **NoOfReplicas**

Table 22.30 This table provides type and value information for the `NoOfReplicas` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>
This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. *This is the recommended value for most production environments.*

---

**Important**

While the maximum possible value for this parameter is 4, setting `NoOfReplicas` to a value greater than 2 is not supported in production.

**Warning**

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- **DataDir**

  **Table 22.31** This table provides type and value information for the DataDir data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- **FileSystemPath**
Table 22.32 This table provides type and value information for the FileSystemPath data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>DataDir</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

Table 22.33 This table provides type and value information for the BackupDataDir data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.

**Important**

The string '/BACKUP' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

**Data Memory, Index Memory, and String Memory**

`DataMemory` and `IndexMemory` are `ndbd` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster.
Note

IndexMemory is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

• DataMemory

Table 22.34 This table provides type and value information for the DataMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by DataMemory is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from DataMemory. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

Resources assigned to DataMemory are used for storing all data and indexes; any memory configured as IndexMemory is automatically added to that used by DataMemory to form a common resource pool.

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get Table is full errors in MySQL client applications even when ndb_mgm -e "ALL REPORT MEMORYUSAGE" shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

You can control the number of partitions per local data manager for a given table by setting the NDB_TABLE option PARTITION_BALANCE to one of the values FOR_RA_BY_LDM, FOR_RA_BY_LDM_X_2, FOR_RA_BY_LDM_X_3, or FOR_RA_BY_LDM_X_4, for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see Section 13.1.20.11, “Setting NDB_TABLE Options”).

Note

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. While still supported for backward compatibility, using MAX_ROWS for this purpose is deprecated; you should use PARTITION_BALANCE instead.

You can also use the MinFreePct configuration parameter to help avoid problems with node restarts.
The memory space allocated by **DataMemory** consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in **NoOfReplicas**.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that **DataMemory** pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The **DataMemory** memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the **DataMemory**. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for **DataMemory** in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

### Table 22.35 This table provides type and value information for the IndexMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The **IndexMemory** parameter is deprecated (and subject to future removal); any memory assigned to **IndexMemory** is allocated instead to the same pool as **DataMemory**, which becomes solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of **IndexMemory** in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

\[
\text{size} = ( \text{fragments} \times 32K) + (\text{rows} \times 18) \times \text{replicas}
\]
fragments is the number of fragments, replicas is the number of replicas (normally 2), and rows is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

\[
\text{memory usage} = \{(8 \times 32K) + (1000000 \times 18)\} \times 2 = \{(8 \times 32768) + (1000000 \times 18)\} \times 2 \\
= (262144 + 18000000) \times 2 \\
= 3862144 \times 2 = 7724288 \text{ bytes} = \sim 7.5 \text{MB}
\]

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\begin{align*}
\text{sample_size} & = \text{key_size} + ((\text{key_attributes} + 1) \times 4) \\
\text{sample_rows} & = \frac{\text{IndexStatSaveSize} \times ((0.01 \times \text{IndexStatSaveScale} \times \log_2(\text{rows} \times \text{sample_size})) + 1)}{\text{sample_size}}
\end{align*}
\]

In the preceding formula, key_size is the size of the ordered index key in bytes, key_attributes is the number of attributes in the ordered index key, and rows is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
\begin{align*}
\text{sample_size} & = 8 + ((1 + 2) \times 4) = 20 \text{ bytes} \\
\text{sample_rows} & = \frac{32K \times ((0.01 \times 100 \times \log_2(1000000 \times 20)) + 1)}{20} \\
& = \frac{32768 \times (1 \times \sim 16.811) + 1}{20} \\
& = \frac{32768 \times \sim 17.811}{20} \\
& = \sim 29182 \text{ rows}
\end{align*}
\]

The expected index memory usage is thus \(2 \times 18 \times 29182 = \sim 1050550 \text{ bytes}\).

In NDB 8.0, the minimum and default value for this parameter is 0 (zero).

- **StringMemory**

Table 22.36 This table provides type and value information for the StringMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>% or bytes</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [ndbd] or [ndbd_default] section of the `config.ini` file. A value between 0 and
100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on
a number of factors including the number of tables, maximum table name size, maximum size of .FRM
files, MaxNoOfTriggers, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB
tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify
StringMemory config parameter: Permanent error: Schema error, in which case you
should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring
in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example (
    a INT NOT NULL,
    b INT NOT NULL,
    c INT NOT NULL,
    PRIMARY KEY(a),
    UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4
bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly 10
bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per
record. The unique constraint is implemented by a separate table with b as primary key and a as a column.
This other table consumes an additional 29 bytes of index memory per record in the example table as well
8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary
key and the unique constraint. We also need 64MB for the records of the base table and the unique index
table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast
access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus,
ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both IndexMemory and DataMemory is that the total database size is the sum of
all data memory and all index memory for each node group. Each node group is used to store replicated
information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data
memory available is 2 × DataMemory for each data node.

It is highly recommended that DataMemory and IndexMemory be set to the same values for all nodes.
Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any
node can be no greater than that of the smallest node in the cluster.

DataMemory and IndexMemory can be changed, but decreasing either of these can be risky; doing
so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being
insufficient memory space. Increasing these values should be acceptable, but it is recommended that
such upgrades are performed in the same manner as a software upgrade, beginning with an update of the
configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct. A proportion (5% by default) of data node resources including DataMemory and
IndexMemory is kept in reserve to insure that the data node does not exhaust its memory when
performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

Table 22.37 This table provides type and value information for the MinFreePct data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

Table 22.38 This table provides type and value information for the MaxNoOfConcurrentTransactions data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4096</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 <code>(0xFFFFFFFF)</code></td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

\[
\text{TotalNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1)
\]
Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting MaxNoOfConcurrentTransactions on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node’s MaxNoOfConcurrentTransactions is sufficient to cover a number of transactions equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then MaxNoOfConcurrentTransactions should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for MaxNoOfConcurrentTransactions should always be no more than the value of MaxNoOfConcurrentOperations.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

• MaxNoOfConcurrentOperations

Table 22.39 This table provides type and value information for the MaxNoOfConcurrentOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>32K</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to total number of concurrent
operations / number of node groups. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of MaxNoOfConcurrentOperations should always be greater than or equal to the value of MaxNoOfConcurrentTransactions.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. MaxNoOfConcurrentOperations will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

• MaxNoOfLocalOperations

Table 22.40 This table provides type and value information for the MaxNoOfLocalOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>UNDEFINED</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as $1.1 \times \text{MaxNoOfConcurrentOperations}$. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

• MaxDMLOperationsPerTransaction

Table 22.41 This table provides type and value information for the MaxDMLOperationsPerTransaction data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set `MaxDMLOperationsPerTransaction` to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- **MaxNoOfConcurrentIndexOperations**

**Table 22.42 This table provides type and value information for the MaxNoOfConcurrentIndexOperations data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- **MaxNoOfFiredTriggers**

**Table 22.43 This table provides type and value information for the MaxNoOfFiredTriggers data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4000</td>
</tr>
</tbody>
</table>
The default value of MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

• TransactionBufferMemory

Table 22.44 This table provides type and value information for the TransactionBufferMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for TransactionBufferMemory is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter ZATTRBUF_FILESIZE (found in ndb/src/kernel/blocks/Dbtc/Dbtc.hpp) set to 4000 × 128 bytes (500KB). A similar buffer for key information, ZDATABUF_FILESIZE (also in Dbtc.hpp) contains 4000 × 16 = 62.5KB of buffer space. Dbtc is the module that handles transaction coordination.

Scans and buffering. There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

• BatchSizePerLocalScan

Table 22.45 This table provides type and value information for the BatchSizePerLocalScan data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>

</tbody>
</table>
**NDB Cluster Configuration Files**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

*BatchSizePerLocalScan* has a strong connection to the *BatchSize* defined in the SQL nodes.

- **LongMessageBuffer**

  Table 22.46 This table provides type and value information for the LongMessageBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- **MaxFKBuildBatchSize**

  Table 22.47 This table provides type and value information for the MaxFKBuildBatchSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- **MaxNoOfConcurrentScans**

  Table 22.48 This table provides type and value information for the MaxNoOfConcurrentScans data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain \( \text{MaxNoOfConcurrentScans} \) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of \( \text{MaxNoOfConcurrentScans} \) is 256. The maximum value is 500.

• \textbf{MaxNoOfLocalScans}

\textbf{Table 22.49} This table provides type and value information for the MaxNoOfLocalScans data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

\[
4 \times \text{MaxNoOfConcurrentScans} \times \text{(# data nodes)} + 2
\]

The minimum value is 32.

• \textbf{MaxParallelCopyInstances}

\textbf{Table 22.50} This table provides type and value information for the MaxParallelCopyInstances data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64</td>
</tr>
</tbody>
</table>
This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, MaxParallelCopyInstances provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- **MaxParallelScansPerFragment**

  Table 22.51 This table provides type and value information for the MaxParallelScansPerFragment data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter is 256.

- **MaxReorgBuildBatchSize**

  Table 22.52 This table provides type and value information for the MaxReorgBuildBatchSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>16 - 512</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- **MaxUIBuildBatchSize**

  Table 22.53 This table provides type and value information for the MaxUIBuildBatchSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
</tbody>
</table>
Memory Allocation

MaxAllocate

Table 22.54 This table provides type and value information for the MaxAllocate data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables, or both) to cause NDB to make sufficient memory available.

Hash Map Size

DefaultHashMapSize

Table 22.55 This table provides type and value information for the DefaultHashMapSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>LDM threads</td>
</tr>
<tr>
<td>Default</td>
<td>3840</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The size of the table hash maps used by NDB is configurable using this parameter. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

Table 22.56 DefaultHashMapSize parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Original hash map size (used in older NDB Cluster releases)</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size (used by default in NDB 8.0)</td>
</tr>
</tbody>
</table>
The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.6 to NDB Cluster 8.0.

Logging and checkpointing. The following [ndbd] parameters control log and checkpoint behavior.

• FragmentLogFileSize

Table 22.57 This table provides type and value information for the FragmentLogFileSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for NoOfFragmentLogFiles.

• InitialNoOfOpenFiles

Table 22.58 This table provides type and value information for the InitialNoOfOpenFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>files</td>
</tr>
<tr>
<td>Default</td>
<td>27</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

• InitFragmentLogFiles

Table 22.59 This table provides type and value information for the InitFragmentLogFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>[see values]</td>
</tr>
<tr>
<td>Default</td>
<td>SPARSE</td>
</tr>
</tbody>
</table>
By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- **SPARSE**. Fragment log files are created sparsely. This is the default value.
- **FULL**. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- **EnablePartialLcp**

Table 22.60 This table provides type and value information for the EnablePartialLcp data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partial LCPs can be modified by the setting for the `RecoveryWork` configuration parameter.

Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- **LcpScanProgressTimeout**

Table 22.61 This table provides type and value information for the LcpScanProgressTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>second</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- **MaxNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- **MaxNoOfSavedMessages**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- **MaxLCPStartDelay**
Table 22.64 This table provides type and value information for the MaxLCPStartDelay data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 600</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set MaxLCPStartDelay, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the [ndbd default] section of the config.ini file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

• NoOfFragmentLogFiles

Table 22.65 This table provides type and value information for the NoOfFragmentLogFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>16</td>
</tr>
<tr>
<td>Range</td>
<td>3 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the FragmentLogFileSize parameter. In scenarios requiring a great many updates, the value for NoOfFragmentLogFiles may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.
If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 \textit{(Out of log file space temporarily)}. This condition prevails until a checkpoint has completed and the log tail can be moved forward.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
</table>

This parameter cannot be changed “on the fly”; you must restart the node using \texttt{--initial}. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using \texttt{--initial} when starting each data node).

- \textbf{RecoveryWork}

**Table 22.66 This table provides type and value information for the RecoveryWork data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>25 - 100</td>
</tr>
<tr>
<td>\textbf{Restart Type}</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter has an effect only when \texttt{EnablePartialLcp} is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for \texttt{RecoveryWork} means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting \texttt{RecoveryWork} to 60 means that the total size of an LCP is roughly 1.6 times the size of the data to be checkpointed. This means that 60\% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at \(1 + \left(1 / \texttt{RecoveryWork}\right)\) times the rate of data changes during checkpoints—thus, when \texttt{RecoveryWork} = 60, it is necessary to write at approximately 2.67 times the change rate. In order words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting \texttt{RecoveryWork} = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.
The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- **InsertRecoveryWork**

  **Table 22.67** This table provides type and value information for the `InsertRecoveryWork` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>40</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 70</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- **EnableRedoControl**

  **Table 22.68** This table provides type and value information for the `EnableRedoControl` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable. Setting `EnablePartialLcp` also disables the adaptive calculation.

**Metadata objects.** The next set of `ndbd` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.
Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

• MaxNoOfAttributes

Table 22.69 This table provides type and value information for the MaxNoOfAttributes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like MaxNoOfTables, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfAttributes attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting MaxNoOfAttributes, it is important to prepare in advance for any ALTER TABLE statements that you might want to perform in the future. This is due to the fact, during the execution of ALTER TABLE on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (greatest_number_of_attributes) has 100 attributes, a good starting point for the value of MaxNoOfAttributes would be 6 * greatest_number_of_attributes = 600.

You should also estimate the average number of attributes per table and multiply this by MaxNoOfTables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual ALTER TABLE after configuring the parameter. If this is not successful, increase MaxNoOfAttributes by another multiple of MaxNoOfTables and test it again.

• MaxNoOfTables

Table 22.70 This table provides type and value information for the MaxNoOfTables data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
</tbody>
</table>
A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like MaxNoOfAttributes, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfTables tables.)

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>8 - 20320</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Note

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed \(2^{32} - 2\) (4294967294).

- MaxNoOfOrderedIndexes

Table 22.71 This table provides type and value information for the MaxNoOfOrderedIndexes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. MaxNoOfOrderedIndexes sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed \(2^{32} - 2\) (4294967294).

- MaxNoOfUniqueHashIndexes
Table 22.72 This table provides type and value information for the MaxNoOfUniqueHashIndexes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the USING HASH option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

**Note**

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- MaxNoOfTriggers

Table 22.73 This table provides type and value information for the MaxNoOfTriggers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- MaxNoOfSubscriptions

Table 22.74 This table provides type and value information for the MaxNoOfSubscriptions data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
</tbody>
</table>
Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- **MaxNoOfSubscribers**

  Table 22.75 This table provides type and value information for the `MaxNoOfSubscribers` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as \(2 \times \text{MaxNoOfTables}\); that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Cluster s, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to \(3 \times \text{MaxNoOfTables}\).

For more information, see Section 22.6, “NDB Cluster Replication”.

- **MaxNoOfConcurrentSubOperations**

  Table 22.76 This table provides type and value information for the `MaxNoOfConcurrentSubOperations` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as **TRUE** by setting them equal to 1 or **Y**, and as **FALSE** by setting them equal to 0 or **N**.

- **LateAlloc**

  **Table 22.77** This table provides type and value information for the LateAlloc data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- **LockPagesInMainMemory**

  **Table 22.78** This table provides type and value information for the LockPagesInMainMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. **(LockPagesInMainMemory uses the mlockall function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by max locked memory. For more information, see ulimit -l and http://linux.die.net/man/2/mlock).**
Note

In older NDB Cluster releases, this parameter was a Boolean. 0 or false was the default setting, and disabled locking. 1 or true enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats true or false for the value of this parameter as an error.

Important

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the MALLOC_ARENA_MAX environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the LD_PRELOAD environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

• StopOnError

Table 22.79 This table provides type and value information for the StopOnError data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and StopOnError is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when StopOnError equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

• CrashOnCorruptedTuple
Table 22.80 This table provides type and value information for the CrashOnCorruptedTuple data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- **Diskless**

Table 22.81 This table provides type and value information for the Diskless data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>true/false (1/0)</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

It is possible to specify NDB Cluster tables as **diskless**, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

**Important**

This feature causes the entire cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

**Diskless** is disabled by default.

- **ODirect**

Table 22.82 This table provides type and value information for the ODirect data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Enabling this parameter causes NDB to attempt using O\_DIRECT writes for LCP, backups, and redo logs, often lowering kswapd and CPU usage. When using NDB Cluster on Linux, enable ODirect if you are using a 2.6 or later kernel.

ODirect is disabled by default.

- ODirectSyncFlag

Table 22.83 This table provides type and value information for the ODirectSyncFlag data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to fsync. The setting for this parameter is ignored if at least one of the following conditions is true:

- ODirect is not enabled.
- InitFragmentLogFiles is set to SPARSE.

Disabled by default.

- RestartOnErrorInsert

Table 22.84 This table provides type and value information for the RestartOnErrorInsert data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- CompressedBackup
Table 22.85 This table provides type and value information for the CompressedBackup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

*CompressedLCP*

Table 22.86 This table provides type and value information for the CompressedLCP data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

**Controlling Timeouts, Intervals, and Disk Paging**

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.
• *TimeBetweenWatchDogCheck*

**Table 22.87** This table provides type and value information for the *TimeBetweenWatchDogCheck* data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>6000</td>
</tr>
<tr>
<td>Range</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

• *TimeBetweenWatchDogCheckInitial*

**Table 22.88** This table provides type and value information for the *TimeBetweenWatchDogCheckInitial* data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>6000</td>
</tr>
<tr>
<td>Range</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This is similar to the *TimeBetweenWatchDogCheck* parameter, except that *TimeBetweenWatchDogCheckInitial* controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

• *StartPartialTimeout*

**Table 22.89** This table provides type and value information for the *StartPartialTimeout* data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>30000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>60000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- **StartFailureTimeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10−15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- **StartNoNodeGroupTimeout**
Table 22.92: This table provides type and value information for the StartNoNodeGroupTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>15000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is configured with `Nodegroup = 65536`, it is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodeGroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

`StartNoNodeGroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See Section 22.5.15, “Adding NDB Cluster Data Nodes Online”, for more information.

- HeartbeatIntervalDbDb

Table 22.93: This table provides type and value information for the HeartbeatIntervalDbDb data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>5000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- HeartbeatIntervalDbApi
Table 22.94 This table provides type and value information for the HeartbeatIntervalDbApi data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for HeartbeatIntervalDbDb.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- **HeartbeatOrder**

Table 22.95 This table provides type and value information for the HeartbeatOrder data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.
Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers host1 and host2, and that these data nodes make up 2 node groups, as shown in the following table:

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on host1</th>
<th>Nodes Running on host2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Group 0:</td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td>Node Group 1:</td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The **HeartbeatOrder** configuration parameter makes the order of heartbeat transmission user-configurable. The default value for **HeartbeatOrder** is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their **HeartbeatOrder** values from lowest to highest (and then directly from the data node having the highest **HeartbeatOrder** to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the **HeartbeatOrder** values as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th><strong>HeartbeatOrder</strong> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set **HeartbeatOrder** for each data node in the cluster in the global configuration (config.ini) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. **All nodes must be restarted in the same order in both rolling restarts.**

You can use **DUMP 908** to observe the effect of this parameter in the data node logs.
Table 22.98 This table provides type and value information for the ConnectCheckIntervalDelay data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 – 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to HeartbeatIntervalDbDb milliseconds.

Such a data node that further fails to respond within an interval of ConnectCheckIntervalDelay milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- TimeBetweenLocalCheckpoints

Table 22.99 This table provides type and value information for the TimeBetweenLocalCheckpoints data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

<td>number of 4-byte words, as a base-2 logarithm</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>0 – 31</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB \(4 \times 2^{20}\) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting TimeBetweenLocalCheckpoints to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster’s workload.

- TimeBetweenGlobalCheckpoints
Table 22.100 This table provides type and value information for the
TimeBetweenGlobalCheckpoints data node configuration parameter

<table>
<thead>
<tr>

</tr>
<tr>
<td>Range</td>
<td>20 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- TimeBetweenGlobalCheckpointsTimeout

Table 22.101 This table provides type and value information for the
TimeBetweenGlobalCheckpointsTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- TimeBetweenEpochs

Table 22.102 This table provides type and value information for the TimeBetweenEpochs data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>

<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32000</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

*TimeBetweenEpochs* is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- *TimeBetweenEpochsTimeout*

Table 22.103 This table provides type and value information for the TimeBetweenEpochsTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 256000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

*TimeBetweenEpochsTimeout* is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- *MaxBufferedEpochs*

Table 22.104 This table provides type and value information for the MaxBufferedEpochs data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or...
threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- **MaxBufferedEpochBytes**

  Table 22.105 This table provides type and value information for the MaxBufferedEpochBytes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>1000 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

  Table 22.107 This table provides type and value information for the TransactionInactiveTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

**Table 22.108** This table provides type and value information for the TransactionDeadlockDetectionTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1200</td>
</tr>
<tr>
<td>Range</td>
<td>50 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- **DiskSyncSize**

**Table 22.109** This table provides type and value information for the DiskSyncSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
</tbody>
</table>
This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is not intended to take the place of TimeBetweenLocalCheckpoints.

Note

When ODirect is enabled, it is not necessary to set DiskSyncSize; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- **MaxDiskWriteSpeed**

  Table 22.110 This table provides type and value information for the MaxDiskWriteSpeed data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>20M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use MaxDiskWriteSpeedOtherNodeRestart. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

- **MaxDiskWriteSpeedOtherNodeRestart**

  Table 22.111 This table provides type and value information for the MaxDiskWriteSpeedOtherNodeRestart data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.
For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MaxDiskWriteSpeedOwnRestart**

  Table 22.112 This table provides type and value information for the `MaxDiskWriteSpeedOwnRestart` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>200M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MinDiskWriteSpeed**

  Table 22.113 This table provides type and value information for the `MinDiskWriteSpeed` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>

<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- **ArbitrationTimeout**
NDB Cluster Configuration Files

Table 22.114 This table provides type and value information for the ArbitrationTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>7500</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- **Arbitration**

Table 22.115 This table provides type and value information for the Arbitration data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
<td>Default, Disabled, WaitExternal</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The **Arbitration** parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the ArbitrationRank settings for the management and API nodes. This is the default value.

- **Disabled.** Setting Arbitration = Disabled in the [ndbd default] section of the config.ini file to accomplishes the same task as setting ArbitrationRank to 0 on all management and API nodes. When Arbitration is set in this way, any ArbitrationRank settings are ignored.

- **WaitExternal.** The Arbitration parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by ArbitrationTimeout has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting Arbitration = WaitExternal in the [ndbd default] section of the config.ini file. For best results with the WaitExternal setting, it is recommended that ArbitrationTimeout be 2 times as long as the interval required by the external cluster manager to perform arbitration.

⚠️ **Important**

This parameter should be used only in the [ndbd default] section of the cluster configuration file. The behavior of the cluster is unspecified when Arbitration is set to different values for individual data nodes.
• **RestartSubscriberConnectTimeout**

Table 22.116 This table provides type and value information for the RestartSubscriberConnectTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>ms</td>
</tr>
<tr>
<td>Default</td>
<td>12000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

**Buffering and logging.** Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

• **UndoIndexBuffer**

Table 22.117 This table provides type and value information for the UndoIndexBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.
This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (Index UNDO buffers overloaded).

**Important**

It is not safe to decrease the value of this parameter during a rolling restart.

- **UndoDataBuffer**

Table 22.118 This table provides type and value information for the UndoDataBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

**Important**

It is not safe to decrease the value of this parameter during a rolling restart.

- **RedoBuffer**

Table 22.119 This table provides type and value information for the RedoBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
</tbody>
</table>
All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster's configuration.

ndbmtd allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of 4 * RedoBuffer bytes.

• EventLogBufferSize

Table 22.120 This table provides type and value information for the EventLogBufferSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>S</td>
</tr>
</tbody>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

• LogLevelStartup
Table 22.121 This table provides type and value information for the LogLevelStartup data node configuration parameter

<table>

<td>N</td>
</tr>
</tbody>
</table>

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 22.5.6.2, “NDB Cluster Log Events”.

• **StartupStatusReportFrequency**

Table 22.131 This table provides type and value information for the StartupStatusReportFrequency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 22.5.1, “Summary of NDB Cluster Start Phases”). When very large values are set for `NoOfFragmentLogFiles,FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
#Total files: 80, Completed: 60  
#Total MBytes: 20480, Completed: 15557
```
These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

### Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- **DictTrace**

  This table provides type and value information for the DictTrace data node configuration parameter:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>undefined</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional `DBDICT` debugging output.

- **WatchdogImmediateKill**

  This table provides type and value information for the WatchDogImmediateKill data node configuration parameter:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

  You can cause threads to be killed immediately whenever watchdog issues occur by enabling the `WatchdogImmediateKill` data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

### Backup parameters.

The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**
Table 22.134 This table provides type and value information for the BackupDataBufferSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as BackupWriteSize, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- **BackupDiskWriteSpeedPct**

Table 22.135 This table provides type and value information for the BackupDiskWriteSpeedPct data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>percent</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 90</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by MinDiskWriteSpeed and MaxDiskWriteSpeed. Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the BackupDiskWriteSpeedPct configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- **BackupLogBufferSize**
The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 22.5.3.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- **BackupReportFrequency**

This table provides type and value information for the BackupReportFrequency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

- **BackupWriteSize**

  Table 22.139 This table provides type and value information for the BackupWriteSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- **BackupMaxWriteSize**

  Table 22.140 This table provides type and value information for the BackupMaxWriteSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.
Additional requirements. When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

NDB Cluster Realtime Performance Parameters

The `ndbd` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

Note

To make use of these parameters, the data node process must be run as system root.

- **LockExecuteThreadToCPU**

  Table 22.141 This table provides type and value information for the LockExecuteThreadToCPU data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>set of CPU IDs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- **LockMaintThreadsToCPU**

  Table 22.142 This table provides type and value information for the LockMaintThreadsToCPU data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>CPU ID</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter specifies the ID of the CPU assigned to handle `NDBCluster` maintenance threads. The value of this parameter is an integer in the range 0 to 65535 (inclusive). There is no default value.

- **RealtimeScheduler**

Table 22.143 This table provides type and value information for the RealtimeScheduler data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 enables real-time scheduling of data node threads. The default is 0 (scheduling disabled).

- **SchedulerExecutionTimer**

Table 22.144 This table provides type and value information for the SchedulerExecutionTimer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times. The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- **SchedulerResponsiveness**

Table 22.145 This table provides type and value information for the SchedulerResponsiveness data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 10</td>
</tr>
</tbody>
</table>

Restart Type: S
Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- **SchedulerSpinTimer**

Table 22.146 This table provides type and value information for the SchedulerSpinTimer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- **BuildIndexThreads**

Table 22.147 This table provides type and value information for the BuildIndexThreads data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 128</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when `COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"` is used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- **TwoPassInitialNodeRestartCopy**
Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to *true* (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- **Numa**

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmtd`. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmtd`; this is because `ndbmtd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.
Multi-Threading Configuration Parameters (ndbmt).  

ndbmt runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the config.ini file. The first method is simply to set an appropriate value for the MaxNoOfExecutionThreads configuration parameter. A second method, makes it possible to set up more complex rules for ndbmt multithreading using ThreadConfig. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

- MaxNoOfExecutionThreads

Table 22.150 This table provides type and value information for the MaxNoOfExecutionThreads multi-threaded data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 72</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter directly controls the number of execution threads used by ndbmt, up to a maximum of 72. Although this parameter is set in [ndbd] or [ndbd default] sections of the config.ini file, it is exclusive to ndbmt and does not apply to ndbd.

Setting MaxNoOfExecutionThreads sets the number of threads for each type as determined by a matrix in the file storage/ndb/src/kernel/vm/mt_thr_config.cpp. This table shows these numbers of threads for possible values of MaxNoOfExecutionThreads.

Table 22.151 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

</table>
There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmtd`, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmtd`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `[Error line number]: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter’s default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

</tbody>
</table>
The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or `ThreadConfig`, but it is possible to effect the change using a node initial restart (NI) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is *not* required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

- `NoOfFragmentLogParts`

**Table 22.152** This table provides type and value information for the `NoOfFragmentLogParts` multi-threaded data node configuration parameter

<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

Set the number of log file groups for redo logs belonging to this `ndbmtd`. The maximum value is 32; the value set must be an even multiple of 4.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmtd` as determined by the setting for `MaxNoOfExecutionThreads`. A configuration where this number is any greater than 4 is disallowed.

See the description of `MaxNoOfExecutionThreads` for more information.

- `ThreadConfig`

</tr>
</tbody>
</table>

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]

entry := type={param[,param[,...]]}

type := ldm | main | recv | send | rep | io | tc | watchdog | idxbld

param := count=number
         | cpubind=cpu_list
         | cpuset=cpu_list
         | spintime=number
         | realtime={0|1}
         | nosend={0|1}
         | thread_prio={0..10}
         | cpubind_exclusive=cpu_list
         | cpuset_exclusive=cpu_list
```

The curly braces ( {...} ) surrounding the list of parameters are required, even if there is only one parameter in the list.

A `param` (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).

- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`. `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpubind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclusive` means that each thread is bound exclusively to the set of CPUs specified.

Only one of `cpubind`, `cpuset`, `cpubind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

`spintime` does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

`realtime` cannot be set for offline index build threads.
• By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.

• `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

**thread_prio settings and effects by platform.** The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

• **Linux and FreeBSD:** We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th><code>nice</code> value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>-4</td>
</tr>
<tr>
<td>7</td>
<td>-8</td>
</tr>
<tr>
<td>8</td>
<td>-12</td>
</tr>
<tr>
<td>9</td>
<td>-16</td>
</tr>
<tr>
<td>10</td>
<td>-20</td>
</tr>
</tbody>
</table>

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

• **Solaris:** Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>25</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>4</td>
<td>35</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
</tbody>
</table>
A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- **Windows**: We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Windows thread priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>THREAD_PRIORITY_LOWEST</td>
</tr>
<tr>
<td>2 - 3</td>
<td>THREAD_PRIORITY_BELOW_NORMAL</td>
</tr>
<tr>
<td>4 - 5</td>
<td>THREAD_PRIORITY_NORMAL</td>
</tr>
<tr>
<td>6 - 7</td>
<td>THREAD_PRIORITY_ABOVE_NORMAL</td>
</tr>
<tr>
<td>8 - 10</td>
<td>THREAD_PRIORITY_HIGHEST</td>
</tr>
</tbody>
</table>

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- **ldm**: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

  Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations, this requirement is relaxed in certain cases, as explained later in this section. (This is also true when this is done using `MaxNoOfExecutionThreads`.) If `IndexMemory` usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% `IndexMemory` usage is recommended in such cases. Otherwise, allocation of memory and LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

  Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

- **tc**: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

  Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).
Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0 - 32

- **main**: Data dictionary and transaction coordinator (DBDIH and DBTC kernel blocks), providing schema management. This is always handled by a single dedicated thread.

  Range: 1 only.

- **recv**: Receive thread (CMVMI kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

  Range: 1 - 16

- **send**: Send thread (CMVMI kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

  Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

  Range: 0 - 16

- **rep**: Replication thread (SUMA kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

  Range: 1 only.

- **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

- **watchdog**: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the `SocketServer` thread, which receives connection setups from other nodes; the `SocketClient` thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

  Range: 1 only.

- **idxbld**: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

  `thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

  If `idxbld` is not specified, the default behavior is as follows:

  - Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
NDB Cluster Configuration Files

- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

  Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or \( N \)) is required to implement the change.

- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (\( NI \)) provided the following two conditions are met:
  a. Each LDM thread handles a maximum of 8 fragments, and
  b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

NDB can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `watchdog`, and `idxbld` threads are not considered execution threads.

- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
ThreadConfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm={count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \ rep={cpubind=10},tc={count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \ send={count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.
In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```plaintext
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \ 
  ldm={count=4,cpuset=4-7,thread_prio=8,spintime=200}, \ 
  tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \ 
  main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```plaintext
ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpuset=5,6,7}, \ 
  io={cpubind=8},idxbld={cpuset=1-8}
ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```plaintext
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \ 
  io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```plaintext
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \ 
  io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFFFFF`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`
Table 22.157 This table provides type and value information for the DiskPageBufferEntries data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>32K pages</td>
</tr>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 1000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- `DiskPageBufferMemory`

Table 22.158 This table provides type and value information for the DiskPageBufferMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that NDB Cluster Disk Data storage always uses $N \times 32$ KB memory where $N$ is some nonnegative integer.

The default value for this parameter is 64M (2000 pages of 32 KB each).

If the value for `DiskPageBufferMemory` is set too low in conjunction with using more than the default number of LDM threads in `ThreadConfig` (for example `{ldm=6...}`). problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase `DiskPageBufferMemory`, or add smaller tablespace files. You may also need to adjust `DiskPageBufferEntries`.

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 22.5.10.20, “The ndbinfo diskpagebuffer Table”, for more information.

- `SharedGlobalMemory`
Table 22.159 This table provides type and value information for the SharedGlobalMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>128M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for table spaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the UNDO_BUFFER_SIZE option used with CREATE LOGFILE GROUP and ALTER LOGFILE GROUP statements, including any default value implied for this options by the setting of the InitialLogFileGroup data node configuration parameter. SharedGlobalMemory can be set in the [ndbd] or [ndbd default] section of the config.ini configuration file, and is measured in bytes.

The default value is 128M.

- DiskIOThreadPool

Table 22.160 This table provides type and value information for the DiskIOThreadPool data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>threads</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before DiskIOThreadPool was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With DiskIOThreadPool, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk
drives can handle many more disk I/O threads than conventional disks, and thus higher values for DiskIOThreadPool.

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  - **FileSystemPathDD**

    Table 22.161 This table provides type and value information for the FileSystemPathDD data node configuration parameter

    | Property             | Value        |
    |----------------------|--------------|
    | Version (or later)   | NDB 8.0.13   |
    | Type or units        | filename     |
    | Default              | [see text]   |
    | Range                | ...          |
    | Restart Type         | IN           |

    If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for FileSystemPathDataFiles, FileSystemPathUndoFiles, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the ADD_DATAFILE clause of a CREATE_TABLESPACE or ALTER_TABLESPACE statement, and for undo log files by specifying a path in the ADD_UNDOFILE clause of a CREATE_LOGFILE_GROUP or ALTER_LOGFILE_GROUP statement. If FileSystemPathDD is not specified, then FileSystemPath is used.

    If a FileSystemPathDD directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with `--initial` causes all files in the directory to be deleted.

  - **FileSystemPathDataFiles**

    Table 22.162 This table provides type and value information for the FileSystemPathDataFiles data node configuration parameter

    | Property             | Value        |
    |----------------------|--------------|
    | Version (or later)   | NDB 8.0.13   |
    | Type or units        | filename     |
    | Default              | [see text]   |
    | Range                | ...          |
    | Restart Type         | IN           |

    If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for FileSystemPathDD. This parameter can be overridden for a given data file by specifying a path in the ADD_DATAFILE clause of a CREATE_TABLESPACE or ALTER_TABLESPACE statement used to create that data file. If FileSystemPathDataFiles is not specified, then FileSystemPathDD is used (or FileSystemPath, if FileSystemPathDD has also not been set).
If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **`FileSystemPathUndoFiles`**

Table 22.163 This table provides type and value information for the `FileSystemPathUndoFiles` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- **`InitialLogFileGroup`**

Table 22.164 This table provides type and value information for the `InitialLogFileGroup` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
```

`file-specification-list:`
The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to 64M. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

Table 22.165 This table provides type and value information for the `InitialTablespace` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```
The name of the tablespace is optional and defaults to \texttt{DEFAULT-TS}. The extent size is also optional; it defaults to \texttt{1M}. The file-specification-list uses the same syntax as shown with the \texttt{InitialLogfileGroup} parameter, the only difference being that each file-specification used with \texttt{InitialTablespace} corresponds to a data file. At least one must be specified in the file-specification-list. Data files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathDataFiles, just as if they had been created as the result of a \texttt{CREATE TABLESPACE} or \texttt{ALTER TABLESPACE} statement.

For example, consider the following line specifying \texttt{InitialTablespace} in the \texttt{[ndbd default]} section of the \texttt{config.ini} file (as with \texttt{InitialLogfileGroup}, this parameter should always be set in the \texttt{[ndbd default]} section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

\begin{verbatim}
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
\end{verbatim}

This is equivalent to the following SQL statements:

\begin{verbatim}
CREATE TABLESPACE TS1
   ADD DATAFILE 'data1.dat'
   EXTENT_SIZE 8M
   INITIAL_SIZE 2G
   ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
   ADD DATAFILE 'data2.dat'
   INITIAL_SIZE 4G
   ENGINE NDBCLUSTER;
\end{verbatim}

This tablespace is created when the data nodes are started with \texttt{--initial}, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as \texttt{Node nodeid killed this node because GCP stop was detected} (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of \texttt{TimeBetweenGlobalCheckpoints} tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for \texttt{DiskPageBufferMemory} as explained previously, it is also very important that the \texttt{DiskIOThreadPool} configuration parameter be set correctly; having \texttt{DiskIOThreadPool} set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the \texttt{TimeBetweenEpochsTimeout} data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The \texttt{TotalSendBufferMemory} and \texttt{OverLoadLimit} data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of
these parameters (as well as SendBufferMemory), see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- **ExtraSendBufferMemory**

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using TotalSendBufferMemory, SendBufferMemory, or both.

- **TotalSendBufferMemory**

  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

See also Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than RedoOverCommitLimit seconds, more than RedoOverCommitCounter times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by DefaultOperationRedoProblemAction. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

  Table 22.166 This table provides type and value information for the RedoOverCommitCounter data node configuration parameter

    | Property          | Value                      |
    |-------------------|----------------------------|
    | Version (or later)| NDB 8.0.13                 |
    | Type or units     | numeric                    |
    | Default           | 3                          |
    | Range             | 0 - 4294967039 (0xFFFFFEFF) |
    | Restart Type      | N                          |

  When RedoOverCommitLimit is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for DefaultOperationRedoProblemAction (by either queuing the operations to be re-trying, or aborting them).

  RedoOverCommitCounter defaults to 3. Set it to 0 to disable the limit.

- **RedoOverCommitLimit**

  Table 22.167 This table provides type and value information for the RedoOverCommitLimit data node configuration parameter

    | Property          | Value                      |
    |-------------------|----------------------------|
    | Version (or later)| NDB 8.0.13                 |
This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts.

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are listed here:

- **StartFailRetryDelay**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use this parameter to set the number of seconds between restart attempts by the data node in the event of failure on startup. The default is 0 (no delay).

Both this parameter and `MaxStartFailRetries` are ignored unless `StopOnError` is equal to 0.

- **MaxStartFailRetries**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use this parameter to limit the number of restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and `StartFailRetryDelay` are ignored unless `StopOnError` is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation.

- **IndexStatAutoCreate**

Table 22.170 This table provides type and value information for the `IndexStatAutoCreate` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.

- **IndexStatAutoUpdate**

Table 22.171 This table provides type and value information for the `IndexStatAutoUpdate` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- **IndexStatSaveSize**
Table 22.172 This table provides type and value information for the IndexStatSaveSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the mysqld memory cache. This consumes IndexMemory.

At least one sample is always produced, regardless of any size limit. This size is scaled by IndexStatSaveScale.

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- **IndexStatSaveScale**

Table 22.173 This table provides type and value information for the IndexStatSaveScale data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- **IndexStatTriggerPct**

Table 22.174 This table provides type and value information for the IndexStatTriggerPct data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>
Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- **IndexStatTriggerScale**

  Table 22.175 This table provides type and value information for the `IndexStatTriggerScale` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

  Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- **IndexStatUpdateDelay**

  Table 22.176 This table provides type and value information for the `IndexStatUpdateDelay` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

  Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

### 22.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

### Note

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster; for information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

- **Id**
Table 22.177 This table provides type and value information for the `Id` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

*NodeId* is the preferred parameter name to use when identifying API nodes. (*Id* continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- ConnectionMap

Table 22.178 This table provides type and value information for the `ConnectionMap` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect.

- NodeId

Table 22.179 This table provides type and value information for the `NodeId` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>
The **NodeId** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**
Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

**NodeId** is the preferred parameter name to use when identifying management nodes. An alias, **Id**, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- **ExecuteOnComputer**

  **Table 22.180** This table provides type and value information for the ExecuteOnComputer API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the **Id** set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

**Important**
This parameter is deprecated, and is subject to removal in a future release. Use the **HostName** parameter instead.

- **HostName**

  **Table 22.181** This table provides type and value information for the HostName API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or **ExecuteOnComputer** is required.

If no **HostName** or **ExecuteOnComputer** is specified in a given `[mysql]` or `[api]` section of the **config.ini** file, then an SQL or API node may connect using the corresponding “slot” from any host.
which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where localhost is assumed for HostName unless otherwise specified.*

- **LocationDomainId**

**Table 22.182** This table provides type and value information for the LocationDomainId API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Assigns an SQL or other API node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

**LocationDomainId** takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- **ArbitrationRank**

**Table 22.183** This table provides type and value information for the ArbitrationRank API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal
configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting `ArbitrationRank` to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- **ArbitrationDelay**

  Table 22.184 This table provides type and value information for the ArbitrationDelay API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- **BatchByteSize**

  Table 22.185 This table provides type and value information for the BatchByteSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16K</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 1M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- **BatchSize**

  Table 22.186 This table provides type and value information for the BatchSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
**Property** | **Value**
---|---
Type or units | records
Default | 256
Range | 1 - 992
Restart Type | N

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- **HeartbeatThreadPriority**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```plaintext
HeartbeatThreadPriority = policy[, priority]
```

- **MaxScanBatchSize**
Table 22.189 This table provides type and value information for the MaxScanBatchSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 16M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- TotalSendBufferMemory

Table 22.190 This table provides type and value information for the TotalSendBufferMemory API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- AutoReconnect

Table 22.191 This table provides type and value information for the AutoReconnect API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is false by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing
one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug 45921)

Note

This parameter can be overridden using the NDB API. For more information, see Ndb_cluster_connection::set_auto_reconnect(), and
Ndb_cluster_connection::get_auto_reconnect().

- DefaultOperationRedoProblemAction

Table 22.192 This table provides type and value information for the DefaultOperationRedoProblemAction API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>QUEUE</td>
</tr>
<tr>
<td>Range</td>
<td>ABORT, QUEUE</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter (along with RedoOverCommitLimit and RedoOverCommitCounter) controls the data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than RedoOverCommitLimit seconds, more than RedoOverCommitCounter times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of DefaultOperationRedoProblemAction, listed here:

- ABORT: Any pending operations from aborted transactions are also aborted.
- QUEUE: Pending operations from transactions that were aborted are queued up to be re-tried. This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when P_TAIL_PROBLEM errors occur.

- DefaultHashMapSize

Table 22.193 This table provides type and value information for the DefaultHashMapSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>buckets</td>
</tr>
<tr>
<td>Default</td>
<td>3840</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The size of the table hash maps used by NDB is configurable using this parameter. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.
### Table 22.194 DefaultHashMapSize parameter values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Old default hash map size</td>
</tr>
<tr>
<td>3840</td>
<td>Hash map size used by default in NDB 8.0</td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

• **Wan**

### Table 22.195 This table provides type and value information for the wan API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

• **ConnectBackoffMaxTime**

### Table 22.196 This table provides type and value information for the ConnectBackoffMaxTime API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `ConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).
Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

- **StartConnectBackoffMaxTime**

**Table 22.197 This table provides type and value information for the StartConnectBackoffMaxTime API node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the StartConnectBackoffMaxTime parameter is applied; otherwise, ConnectBackoffMaxTime is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches StartConnectBackoffMaxTime milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** You can use the ApiVerbose configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds DBDICT debugging output as well. (Bug #20638450) See also DUMP 1229.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using SHOW STATUS in the mysql client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+----------------+|
| Variable_name               | Value          |
+-----------------------------+----------------+|
| Ndb_cluster_node_id         | 5              |
| Ndb_config_from_host        | 198.51.100.112 |
| Ndb_config_from_port        | 1186           |
| Ndb_number_of_storage_nodes | 4              |
+-----------------------------+----------------+|
4 rows in set (0.02 sec)
```
For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

22.3.3.8 Defining the System

The [system] section is used for parameters applying to the cluster as a whole. The Name system parameter is used with MySQL Enterprise Monitor; ConfigGenerationNumber and PrimaryMGMNode are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, it is not necessary to have a [system] section in the config.ini file.

More information about these parameters can be found in the following list:

• ConfigGenerationNumber

Table 22.198 This table provides type and value information for the ConfigGenerationNumber system configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Configuration generation number. This parameter is currently unused.

• Name

Table 22.199 This table provides type and value information for the Name system configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.
You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- **PrimaryMGMNode**

  *Table 22.200 This table provides type and value information for the PrimaryMGMNode system configuration parameter*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Node ID of the primary management node. This parameter is currently unused.

### 22.3.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 5.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 22.3, “Configuration of NDB Cluster”.

**MySQL Server Options for NDB Cluster**

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.7, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”. For information about command-line options used with `NDB` utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 22.4, “NDB Cluster Programs”.

- **--ndbcluster**

  *Table 22.201 Type and value information for ndbcluster*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbcluster</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>

</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>Default, Range</td>
<td>FALSE (Version: 8.0)</td>
</tr>
</tbody>
</table>
The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the `NDB` storage engine is not enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

Let `ALTER TABLE` and other DDL statements use copying operations on `NDB` tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=#`

---

### Table 22.202 Type and value information for ndb-allow-copying-alter-table

<tr>
<td>Notes</td>
<td>DESCRIPTION: Number of connections to the cluster used by MySQL</td>
</tr>
</tbody>
</table>

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

---

**Important**

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must not use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`
Table 22.205 Type and value information for ndb-cluster-connection-pool-nodeids

</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.</td>
</tr>
</tbody>
</table>

This option can be used to set the size (in bytes) for batching of BLOB data reads in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.
Note
In NDB API applications, you can control BLOB write batching with the 
\texttt{setMaxPendingBlobReadBytes()} and \texttt{getMaxPendingBlobReadBytes()} 
methods.

- \texttt{--ndb-blob-write-batch-bytes=bytes}

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: KEYHASH / LINHASH, KEYHASH (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)</td>
</tr>
</tbody>
</table>

Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- `--ndb-log-apply-status`

**Table 22.212 Type and value information for ndb-log-apply-status**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-log-apply-status</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: OFF (Version: 8.0)</td>
</tr>
</tbody>
</table>
Causes a slave mysqld to log any updates received from its immediate master to the mysql.ndb_apply_status table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the mysql.ndb_apply_status tables of any MySQL servers configured as slaves of the current mysqld.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to ndb_apply_status tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the --ndbcluster option.

- **--ndb-log-empty-epochs=[ON|OFF]**

### Table 22.213 Type and value information for ndb-log-empty-epochs

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-log-empty-epochs</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td></td>
<td>OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.</td>
</tr>
</tbody>
</table>

Causes epochs during which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

By default this option is disabled. Disabling --ndb-log-empty-epochs causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in ndb_binlog_index.

Because --ndb-log-empty-epochs=1 causes the size of the ndb_binlog_index table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.
• \texttt{--ndb-log-empty-update=[ON|OFF]}

**Table 22.214 Type and value information for ndb-log-empty-update**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-log-empty-update</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>

<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when \texttt{--log-slave-updates} is enabled.</td>
</tr>
</tbody>
</table>

Causes updates that produced no changes to be written to the \texttt{ndb_apply_status} and \texttt{ndb_binlog_index} tables, even when \texttt{--log-slave-updates} is enabled.

By default this option is disabled (OFF). Disabling \texttt{--ndb-log-empty-update} causes updates with no changes not to be written to the binary log.

• \texttt{--ndb-log-exclusive-reads=[0|1]}

**Table 22.215 Type and value information for ndb-log-exclusive-reads**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-log-exclusive-reads</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range 0 (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts</td>
</tr>
</tbody>
</table>

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the \texttt{ndb_log_exclusive_reads} system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.
• --ndb-log-orig

Table 22.216 Type and value information for ndb-log-orig

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-log-orig</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table</td>
</tr>
</tbody>
</table>

Log the originating server ID and epoch in the ndb_binlog_index table.

Note

This makes it possible for a given epoch to have multiple rows in ndb_binlog_index, one for each originating epoch.

For more information, see Section 22.6.4, “NDB Cluster Replication Schema and Tables”.

• --ndb-log-transaction-id

Table 22.217 Type and value information for ndb-log-transaction-id

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-log-transaction-id</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.</td>
</tr>
</tbody>
</table>

Causes a slave mysql to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, --log-bin-use-v1-row-events must be set to FALSE in order to use this option.
This option is not supported in mainline MySQL Server 8.0. It is required to enable NDB Cluster Replication conflict detection and resolution using the \texttt{NDB\$EPOCH\_TRANS()} function (see \texttt{NDB\$EPOCH\_TRANS()}).

The default value is \texttt{FALSE}.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- \texttt{--ndb-log-update-minimal}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>\texttt{ndb-log-update-minimal}</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: OFF (Version: NDB 8.0)</td>
</tr>
<tr>
<td></td>
<td>Default, Range: OFF (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log updates in a minimal format.</td>
</tr>
</tbody>
</table>

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than NDB.

- \texttt{--ndb-mgmd-host=host[:port]}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>\texttt{ndb-mgmd-host}</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>No</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: localhost:1186 (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Set the host (and port, if desired) for connecting to management server</td>
</tr>
</tbody>
</table>
Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the --ndb-connectstring option instead.

* --ndb-nodeid=#

**Table 22.220 Type and value information for ndb-nodeid**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-nodeid</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range / 1 - 63 (Version: NDB 8.0)</td>
</tr>
<tr>
<td></td>
<td>Default, Range / 1 - 255 (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB Cluster node ID for this MySQL server</td>
</tr>
</tbody>
</table>

Set this MySQL server's node ID in an NDB Cluster.

The --ndb-nodeid option overrides any node ID set with --ndb-connectstring, regardless of the order in which the two options are used.

In addition, if --ndb-nodeid is used, then either a matching node ID must be found in a [mysqld] or [api] section of config.ini, or there must be an "open" [mysqld] or [api] section in the file (that is, a section without a NodeId or Id parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable Ndb_cluster_node_id in the output of SHOW STATUS, and as cluster_node_id in the connection row of the output of SHOW ENGINE NDDBCLUSTER STATUS.

For more information about node IDs for NDB Cluster SQL nodes, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

* --ndb_optimization_delay=milliseconds

**Table 22.221 Type and value information for ndb_optimization_delay**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>

</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>No</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Disable the NDB Cluster storage engine</td>
</tr>
</tbody>
</table>
Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 22.3.1, “Quick Test Setup of NDB Cluster”, for an example.

**NDB Cluster System Variables**

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the `NDB` storage engine. For system variables not specific to NDB Cluster, see Section 5.1.8, “Server System Variables”. For general information on using system variables, see Section 5.1.9, “Using System Variables”.

- `ndb_autoincrement_prefetch_sz`

**Table 22.229 Type and value information for ndb_autoincrement_prefetch_sz**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_autoincrement_prefetch_sz</code></td>

<tr>
<td></td>
<td>Default, Range 32 / 1 - 256 (Version: NDB 8.0)</td>
</tr>
<tr>
<td></td>
<td>Default, Range 1 / 1 - 65536 (Version: NDB 8.0)</td>
</tr>
<tr>
<td></td>
<td>Default, Range 1 / 1 - 65536 (Version: NDB 8.0)</td>
</tr>
<tr>
<td></td>
<td>Notes DESCRIPTION: NDB auto-increment prefetch size</td>
</tr>
</tbody>
</table>

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The minimum and default value is 1. The maximum value for `ndb_autoincrement_prefetch_sz` is 65536.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time. The default value is 1.
Important
This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_cache_check_time</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: 0 / - (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache</td>
</tr>
</tbody>
</table>

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

Note
The query cache `ndb_cache_check_time` are deprecated in MySQL 5.7; the query cache was removed in MySQL 8.0.

- `ndb_clear_apply_status`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_clear_apply_status</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
By the default, executing **RESET SLAVE** causes an NDB Cluster replication slave to purge all rows from its **ndb_apply_status** table. You can disable this by setting **ndb_clear_apply_status=OFF**.

* **ndb_data_node_neighbour**

Table 22.232  Type and value information for ndb_data_node_neighbour

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>0 / 0 - 255 (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Specifies cluster data node &quot;closest&quot; to this MySQL Server, for transaction hinting and fully replicated tables</td>
</tr>
</tbody>
</table>

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See Section 13.1.20.11, "Setting NDB_TABLE Options", for further information.

Note

An equivalent method **set_data_node_neighbour()** is provided for use in NDB API applications.

* **ndb_default_column_format**

Table 22.233  Type and value information for ndb_default_column_format

<table>

</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default, Range</td>
<td>0 / 0 - 4294967295 (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).</td>
</tr>
</tbody>
</table>

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- **ndb_extra_logging**

#### Table 22.238 Type and value information for ndb_extra_logging

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_extra_logging</td>

<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>0 / - (Version: 8.0)</td>
</tr>
<tr>
<td>Default, Range</td>
<td>1 / - (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log</td>
</tr>
</tbody>
</table>

This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- **ndb_force_send**

#### Table 22.239 Type and value information for ndb_force_send

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

**Notes**

DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces

This variable is used for providing tuning options for NDB index statistics generation. The list consists of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting **ndb_index_stat_option** are not changed from their default values. For example, you can set **ndb_index_stat_option** = 'loop_idle=1000ms,cache_limit=32M'.

Time values can be optionally suffixed with **h** (hours), **m** (minutes), or **s** (seconds). Millisecond values can optionally be specified using **ms**; millisecond values cannot be specified using **h**, **m**, or **s**.) Integer values can be suffixed with **K**, **M**, or **G**.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
This variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when \texttt{ndb\_join\_pushdown} is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to \texttt{mysqld}. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, \texttt{ndb\_join\_pushdown} is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use exactly the same data type.
   
   This means that expressions such as \texttt{t1.a = t2.a + constant} cannot be pushed down, and that (for example) a join on an \texttt{INT} column and a \texttt{BIGINT} column also cannot be pushed down.

2. Queries referencing \texttt{BLOB} or \texttt{TEXT} columns are not supported.

3. Explicit locking is not supported; however, the NDB storage engine's characteristic implicit row-based locking is enforced.

   This means that a join using \texttt{FOR UPDATE} cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the \texttt{ref}, \texttt{eq\_ref}, or \texttt{const} access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using \texttt{eq\_ref}.

   If the root of the pushed join is an \texttt{eq\_ref} or \texttt{const}, only child tables joined by \texttt{eq\_ref} can be appended. (A table joined by \texttt{ref} is likely to become the root of another pushed join.)

   If the query optimizer decides on Using join cache for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [LINEAR] HASH, LIST, or RANGE currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with \texttt{EXPLAIN}; when the join can be pushed down, you can see references to the pushed join in the \texttt{Extra} column of the output, as shown in this example:
### Table 2.1: Query Execution Information

<table>
<thead>
<tr>

<td>Child of 'e' in pushed join@1</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

---

**Note**

If inner joined child tables are joined by `ref`, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfo.counters` table that belong to the DBSPJ kernel block. See Section 22.5.10.10, "The ndbinfo counters Table", for information about these counters. See also The DBSPJ Block, in the NDB Cluster API Developer Guide.

- `ndb_log_apply_status`
### Table 22.245 Type and value information for ndb_log_apply_status

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_apply_status</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID</td>
</tr>
</tbody>
</table>

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

### Table 22.246 Type and value information for ndb_log_bin

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_bin</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: ON (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with <code>--log-bin</code>.</td>
</tr>
</tbody>
</table>

Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0.16 and later, `ndb_log_bin` defaults to 0 (FALSE).

- `ndb_log_binlog_index`

### Table 22.247 Type and value information for ndb_log_binlog_index

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_binlog_index</code></td>
</tr>
</tbody>
</table>
Causes a mapping of epochs to positions in the binary log to be inserted into the ndb_binlog_index table. Setting this variable has no effect if binary logging is not already enabled for the server using log_bin. (In addition, ndb_log_bin must not be disabled.) ndb_log_binlog_index defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- ndb_log_empty_epochs

**Table 22.248  Type and value information for ndb_log_empty_epochs**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_empty_epochs</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled</td>
</tr>
</tbody>
</table>

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in ndb_binlog_index.

- ndb_log_empty_update

**Table 22.249  Type and value information for ndb_log_empty_update**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_empty_update</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
</tbody>
</table>
When this variable is set to **ON** (1), update transactions with no changes are written to the binary log, even when `--log-slave-updates` is enabled.

- **ndb_log_exclusive_reads**

**Table 22.250  Type and value information for ndb_log_exclusive_reads**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_exclusive_reads</td>

</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts</td>
</tr>
</tbody>
</table>

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of **ndb_log_exclusive_reads** to 1. 0, which disables such locking, is the default.

For more information, see **Read conflict detection and resolution**.

- **ndb_log_orig**

**Table 22.251  Type and value information for ndb_log_orig**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_orig</td>

<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether NDB transaction IDs are written into the binary log (Read-only.)</td>
</tr>
</tbody>
</table>

This read-only, Boolean system variable shows whether a slave mysqld writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with NDB$EPOCH_TRANS() conflict detection). To change the setting, use the --ndb-log-transaction-id option.

ndb_log_transaction_id is not supported in mainline MySQL Server 8.0.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **ndb_optimized_node_selection**

**Table 22.253 Type and value information for ndb_optimized_node_selection**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range ON (Version: 8.0)</td>
</tr>
<tr>
<td></td>
<td>Default, Range 3 / 0 - 3 (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator</td>
</tr>
</tbody>
</table>

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to localhost; SCI connection; TCP connection from a host other than localhost.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- **0**: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- **1**: Proximity to the SQL node is used to determine the transaction coordinator.
- **2**: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
- **3**: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.
Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- `ndb_read_backup`

**Table 22.254 Type and value information for ndb_read_backup**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_read_backup</code></td>

<td>Default, Range</td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Enable read from any replica</td>
</tr>
</tbody>
</table>

Enable read from any replica for any NDB table subsequently created.

- `ndb_recv_thread_activation_threshold`

**Table 22.255 Type and value information for ndb_recv_thread_activation_threshold**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_recv_thread_activation_threshold</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>No</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td>Default, Range</td>
<td>8 / 0 (MIN_ACTIVATION_THRESHOLD) - 16 (MAX_ACTIVATION_THRESHOLD) (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)</td>
</tr>
</tbody>
</table>

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-activation-threshold` option.
• `ndb_recv_thread_cpu_mask`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_recv_thread_cpu_mask</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range [empty] (Version: 8.0)</td>
</tr>
</tbody>
</table>

**Notes**: DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask; for example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-cpu-mask` option.

• `ndb_report_thresh_binlog_epoch_slip`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_report_thresh_binlog_epoch_slip</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range 3 / 0 - 256 (Version: 8.0)</td>
</tr>
</tbody>
</table>

**Default, Range**: 10 / 0 - 256 (Version: NDB 8.0)

**Notes**: DESCRIPTION: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates `BUFFERED_EPOCHS_OVER_THRESHOLD` event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.
This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see Section 22.5.7.3, “Event Buffer Reporting in the Cluster Log”). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

- **ndb_report_thresh_binlog_mem_usage**

  **Table 22.258 Type and value information for ndb_report_thresh_binlog_mem_usage**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_report_thresh_binlog_mem_usage</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: 10 / 0 - 10 (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status</td>
</tr>
</tbody>
</table>

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- **ndb_row_checksum**

  **Table 22.259 Type and value information for ndb_row_checksum**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_row_checksum</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default, Range</td>
<td>1 / 0 - 1 (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, set row checksums; enabled by default</td>
</tr>
</tbody>
</table>
Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are not used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- `slave_allow_batching`

### Table 22.260 Type and value information for `slave_allow_batching`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>slave_allow_batching</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>off (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Turns update batching on and off for a replication slave</td>
</tr>
</tbody>
</table>

Whether or not batched updates are enabled on NDB Cluster replication slaves.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see Section 22.6.6, "Starting NDB Cluster Replication (Single Replication Channel)".

- `ndb_show_foreign_key_mock_tables`

### Table 22.261 Type and value information for `ndb_show_foreign_key_mock_tables`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_show_foreign_key_mock_tables</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Show the mock tables used to support foreign_key_checks=0</td>
</tr>
</tbody>
</table>
Show the mock tables used by NDB to support foreign_key_checks=0. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of SHOW CREATE TABLE.

- ndb_slave_conflict_role

Table 22.262 Type and value information for ndb_slave_conflict_role

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_slave_conflict_role</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range, PRIMARY, SECONDARY, PASS (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.</td>
</tr>
</tbody>
</table>

Determine the role of this SQL node (and NDB Cluster) in a circular ("active-active") replication setup. ndb_slave_conflict_role can take any one of the values PRIMARY, SECONDARY, PASS, or NULL (the default). The slave SQL thread must be stopped before you can change ndb_slave_conflict_role. In addition, it is not possible to change directly between PASS and either of PRIMARY or SECONDARY directly; in such cases, you must ensure that the SQL thread is stopped, then execute SET @@GLOBAL.ndb_slave_conflict_role = 'NONE' first.

For more information, see Section 22.6.11, "NDB Cluster Replication Conflict Resolution".

- ndb_table_no_logging

Table 22.263 Type and value information for ndb_table_no_logging

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_table_no_logging</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range, FALSE (Version: 8.0)</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.</td>
</tr>
</tbody>
</table>

When this variable is set to **ON** or **1**, it causes **NDB** tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using **ENGINE NDB** when **ndb_table_no_logging** is enabled, and continues to apply for the lifetime of the table, even if **ndb_table_no_logging** is later changed. Suppose that **A**, **B**, **C**, and **D** are tables that we create (and perhaps also alter), and that we also change the setting for **ndb_table_no_logging** as shown here:

```sql
SET @@ndb_table_no_logging = 1;
CREATE TABLE A ... ENGINE NDB;
CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;
ALTER TABLE B ENGINE NDB;
SET @@ndb_table_no_logging = 0;
CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables **A** and **B** are not checkpointed; **A** was created with **ENGINE NDB** and **B** was altered to use **NDB**, both while **ndb_table_no_logging** was enabled. However, tables **C** and **D** are logged; **C** was altered to use **NDB** and **D** was created using **ENGINE NDB**, both while **ndb_table_no_logging** was disabled. Setting **ndb_table_no_logging** back to **1** or **ON** does not cause table **C** or **D** to be checkpointed.

**Note**

**ndb_table_no_logging** has no effect on the creation of **NDB** table schema files; to suppress these, use **ndb_table_temporary** instead.

- **ndb_table_temporary**

**Table 22.264** Type and value information for **ndb_table_temporary**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>

</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged</td>
</tr>
</tbody>
</table>

When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note
Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- **ndb_use_copying_alter_table**

Table 22.265 Type and value information for ndb_use_copying_alter_table

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Use copying ALTER TABLE operations in NDB Cluster</td>
</tr>
</tbody>
</table>

Forces NDB to use copying of tables in the event of problems with online ALTER TABLE operations. The default value is OFF.

- **ndb_use_exact_count**

Table 22.266 Type and value information for ndb_use_exact_count

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_use_exact_count</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>ON (Version: 8.0)</td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Use exact row count when planning queries</td>
</tr>
</tbody>
</table>
Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is OFF, which allows for faster queries overall.

- **ndb_use_transactions**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_use_transactions</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>

<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Type</td>
<td>No</td>
</tr>
<tr>
<td>Default, Range</td>
<td>32 / 7 - 32 (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value</td>
</tr>
</tbody>
</table>

The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.

If the value of server_id greater than or equal to 2 to the power of server_id_bits, mysqld refuses to start.

This system variable is supported only by NDB Cluster. server_id_bits is not supported by the standard MySQL Server.

- transaction_allow_batching
Table 22.271 Type and value information for transaction_allow_batching

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>transaction_allow_batching</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td></td>
<td>FALSE (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.</td>
</tr>
</tbody>
</table>

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, autocommit must first be disabled by setting it to 0 or OFF; otherwise, setting transaction_allow_batching has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit COMMIT if desired) before issuing a SELECT.

**Important**

transaction_allow_batching should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the ndbinfo information database.

- ndbinfo_database

Table 22.272 Type and value information for ndbinfo_database

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbinfo_database</td>

<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td></td>
<td>ndbinfo (Version: 8.0)</td>
</tr>
</tbody>
</table>
Shows the name used for the NDB information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=name`, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes`

**Table 22.273  Type and value information for ndbinfo_max_bytes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbinfo_max_bytes</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range 0 / - (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Used for debugging only</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- `ndbinfo_max_rows`

**Table 22.274  Type and value information for ndbinfo_max_rows**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbinfo_max_rows</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range 10 / - (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Used for debugging only</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- `ndbinfo_offline`
Table 22.275  Type and value information for ndbinfo_offline

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbinfo_offline</td>

<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views</td>
</tr>
</tbody>
</table>

Place the ndbinfo database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- ndbinfo_show_hidden

Table 22.276  Type and value information for ndbinfo_show_hidden

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbinfo_show_hidden</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range OFF (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.</td>
</tr>
</tbody>
</table>

Whether or not the ndbinfo database's underlying internal tables are shown in the mysql client. The default is OFF.

- ndbinfo_table_prefix

Table 22.277  Type and value information for ndbinfo_table_prefix

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndbinfo_table_prefix</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>ndb$ (Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: The prefix to use for naming ndbinfo internal base tables</td>
</tr>
</tbody>
</table>

The prefix used in naming the ndbinfo database’s base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version`

Table 22.278  Type and value information for `ndbinfo_version`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>

</tr>
<tr>
<td>Default, Range</td>
<td>(Version: 8.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: The version of the ndbinfo engine; read only</td>
</tr>
</tbody>
</table>

Shows the version of the `ndbinfo` engine in use; read-only.

NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the NDB storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 5.1.10, “Server Status Variables”.

- `Handler_discover`

The MySQL server can ask the NDBCLUSTER storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_bytes_sent_count_session`
Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count_slave**
  Amount of data (in bytes) sent to the data nodes by this slave.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count**
  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_session**
  Amount of data (in bytes) received from the data nodes in this client session.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_slave**
  Amount of data (in bytes) received from the data nodes by this slave.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count**
  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count_injector**
  The number of row change events received by the NDB binlog injector thread.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count**
  The number of row change events received by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count_injector**
  The number of events received, other than row change events, by the NDB binary log injector thread.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count**
  The number of events received, other than row change events, by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count_injector**
  The number of bytes of events received by the NDB binlog injector thread.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count**
  The number of bytes of events received by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_session**
  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_slave**

  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count**

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_session**

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_slave**

  The number of scans by this slave that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count**

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_session**

  The number of range scans that have been started in this client session.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_slave**

  The number of range scans that have been started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count**

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count_slave**

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count_session**
The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• `Ndb_api_scan_batch_count_slave`

The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• `Ndb_api_scan_batch_count`

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• `Ndb_api_table_scan_count_session`

The number of table scans that have been started in this client session, including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• `Ndb_api_table_scan_count_slave`

The number of table scans that have been started by this slave, including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count_session**
  
  The number of transactions aborted in this client session.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count_slave**
  
  The number of transactions aborted by this slave.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
  
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count**
  
  The number of transactions aborted by this MySQL Server (SQL node).
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_session**
  
  The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_slave**
  
  The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
  
  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count**
  
  The number of transactions closed by this MySQL Server (SQL node).
The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_session**

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_slave**

  The number of transactions committed by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count**

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_slave**

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.
• **Ndb_api_trans_local_read_row_count**

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_start_count_session**

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_start_count_slave**

The number of transactions started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_start_count**

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_session**

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_slave**

The number of operations by this slave based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count**
The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_session**

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_slave**

  The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count_session**

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count_slave**

  The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_nanos_count_session**

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_nanos_count_slave**

  Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_nanos_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count_session**

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.
• Ndb_api_wait_scan_result_count_slave

The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• Ndb_api_wait_scan_result_count

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

• Ndb_cluster_node_id

If the server is acting as an NDB Cluster node, then the value of this variable is the node ID in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

• Ndb_config_from_host

If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

• Ndb_config_from_port

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

• Ndb_conflict_fn_max_del_win

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_conflict_fn_max

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• Ndb_conflict_fn_old

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given *mysqld* since the last time it was restarted.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given *mysqld* since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch2**

  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the master designated as the primary since the last time it was restarted.

  For more information, see `NDB$EPOCH2()`.

- **Ndb_conflict_fn_epoch_trans**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given *mysqld* since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch2_trans**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given *mysqld* since the last time it was restarted.

  For more information, see `NDB$EPOCH2_TRANS()`.

- **Ndb_conflict_last_conflict_epoch**

  The most recent epoch in which a conflict was detected on this slave. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_reflected_op_discard_count**

  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_reflected_op_prepare_count**

  When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.
• **Ndb_conflict_refresh_op_count**

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_last_stable_epoch**

Number of rows found to be in conflict by a transactional conflict function

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_trans_row_conflict_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given mysqld since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as Ndb_conflict_fn_epoch_trans.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_row_reject_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only Ndb_conflict_trans_row_conflict_count, but any rows in or dependent on conflicting transactions.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_reject_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_detect_iter_count**

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_conflict_commit_count**

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_epoch_delete_delete_count**
When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- **Ndb_execute_count**
  Provides the number of round trips to the NDB kernel made by operations.

- **Ndb_last_commit_epoch_server**
  The epoch most recently committed by NDB.

- **Ndb_last_commit_epoch_session**
  The epoch most recently committed by this NDB client.

- **Ndb_number_of_data_nodes**
  If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.
  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_pushed_queries_defined**
  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.
  \[\text{Note}\]
  Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- **Ndb_pushed_queries_dropped**
  The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- **Ndb_pushed_queries_executed**
  The number of joins successfully pushed down to NDB and executed there.

- **Ndb_pushed_reads**
  The number of rows returned to `mysql` from the NDB kernel by joins that were pushed down.
  \[\text{Note}\]
  Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

- **Ndb_pruned_scan_count**
  This variable holds a count of the number of scans executed by NDBCLUSTER since the NDB Cluster was last started where NDBCLUSTER was able to use partition pruning.
  Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- **Ndb_scan_count**
This variable holds a count of the total number of scans executed by NDBCLUSTER since the NDB Cluster was last started.

- **Ndb_slave_max_replicated_epoch**

  The most recently committed epoch on this slave. You can compare this value with Ndb_conflict_last_conflict_epoch; if Ndb_slave_max_replicated_epoch is the greater of the two, no conflicts have yet been detected.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_system_name**

  If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

### 22.3.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more [tcp] sections in the config.ini file. Each [tcp] section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters NodeId1 and NodeId2, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the [tcp default] section.

**Important**

Any [tcp] sections in the config.ini file should be listed last, following all other sections in the file. However, this is not required for a [tcp default] section. This requirement is a known issue with the way in which the config.ini file is read by the NDB Cluster management server.

Connection parameters which can be set in [tcp] and [tcp default] sections of the config.ini file are listed here:

- **NodeId1**

  **Table 22.279** This table provides type and value information for the NodeId1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>
To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeId2**

  Table 22.280 This table provides type and value information for the `NodeId2 TCP` configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

- **HostName1**

  Table 22.281 This table provides type and value information for the `HostName1 TCP` configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

  Table 22.282 This table provides type and value information for the `HostName1 TCP` configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
</tbody>
</table>
The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **OverloadLimit**

  **Table 22.283** This table provides type and value information for the OverloadLimit TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

  This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

- **SendBufferMemory**

  **Table 22.284** This table provides type and value information for the SendBufferMemory TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

  If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

  The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.
### SendSignalId

#### Table 22.285 This table provides type and value information for the SendSignalId TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

### Checksum

#### Table 22.286 This table provides type and value information for the Checksum TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

### PreSendChecksum

#### Table 22.287 This table provides type and value information for the PreSendChecksum TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if Checksum is not also enabled.

### ReceiveBufferMemory
Table 22.288 This table provides type and value information for the ReceiveBufferMemory TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **TCP_RCV_BUF_SIZE**

Table 22.289 This table provides type and value information for the TCP_RCV_BUF_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_SND_BUF_SIZE**

Table 22.290 This table provides type and value information for the TCP_SND_BUF_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_MAXSEG_SIZE**
Table 22.291 This table provides type and value information for the TCP_MAXSEG_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TcpBind_INADDR_ANY**

  Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

- **Group**

  When ndb_optimized_node_selection is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

### 22.3.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster config.ini file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```markdown
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
```
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>NodeId1=3</th>
<th>NodeId2=4</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostName1=1.1.0.1</td>
<td>HostName2=1.1.0.2</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster’s overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

**Note**

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

#### 22.3.3.12 NDB Cluster Shared-Memory Connections

The shared memory (SHM) transporter is distinguished from other NDB transporters by the fact that signals are transported by writing in memory rather than on a socket. NDB Cluster attempts to use the shared memory transporter and configure it automatically between data nodes and API nodes on the same host. You can use `[shm]` sections in the `config.ini` file to define shared memory connections between nodes in the cluster explicitly. To enable explicit shared memory connections, set the `UseShm` SHM configuration parameter to `true`. When explicitly defining shared memory as the connection method, it is also necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other SHM parameters have default values that should work well in most cases.

For optimum performance, you can define a spin time for the SHM transporter (`ShmSpinTime` parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

- **Checksum**

  **Table 22.292** This table provides type and value information for the Checksum shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

  This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **HostName1**

  **Table 22.293** This table provides type and value information for the HostName1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
</tbody>
</table>
### Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**

- **HostName2**

Table 22.294 This table provides type and value information for the HostName1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**

- **NodeId1**

Table 22.295 This table provides type and value information for the NodeId1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

**Restart Type**

- **NodeId2**

Table 22.296 This table provides type and value information for the NodeId2 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

- **NodeId1**

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.

- **NodeId2**
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.

- **NodeIdServer**

  **Table 22.297** This table provides type and value information for the NodeIdServer shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Identify the server end of a shared memory connection.

- **OverloadLimit**

  **Table 22.298** This table provides type and value information for the OverloadLimit shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, and Section 22.5.10.44, “The ndbinfo transporters Table”, for more information.

- **PreSendChecksum**

  **Table 22.299** This table provides type and value information for the PreSendChecksum shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
</tbody>
</table>
If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if Checksum is not also enabled.

### SendBufferMemory

Table 22.300 This table provides type and value information for the SendBufferMemory shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Size (in bytes) of the shared shared memory buffer for signals sent from this node using a shared memory connection.

### SendSignalId

Table 22.301 This table provides type and value information for the SendSignalId shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

### ShmKey

Table 22.302 This table provides type and value information for the ShmKey shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- **ShmSize**

Table 22.303 This table provides type and value information for the ShmSize shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by ShmSize. The default value is 1MB.

- **ShmSpinTime**

Table 22.304 This table provides type and value information for the ShmSpinTime shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

When receiving, the time to wait before sleeping, in milliseconds.

- **SgnNum**

Table 22.305 This table provides type and value information for the Signum shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.
The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

- **UseShm**

Table 22.306 This table provides type and value information for the `UseShm` shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Enable shared memory connections between nodes. Set `true` to enable.

### 22.3.3.13 SCI Transport Connections in NDB Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in NDB Cluster requires specialized hardware as well as specially-built MySQL binaries; compiling such binaries is not supported using an NDB 8.0 distribution.

The following parameters are present in NDB source code as well as the output of `ndb_config` and other NDB programs, but are currently nonfunctional:

- **NodeId1**

Table 22.307 This table provides type and value information for the `NodeId1` SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeId2**

Table 22.308 This table provides type and value information for the `NodeId2` SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
</tbody>
</table>
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **Host1SciId0**

  Table 22.309 This table provides type and value information for the Host1SciId0 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- **Host1SciId1**

  Table 22.310 This table provides type and value information for the Host1SciId1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- **Host2SciId0**

  Table 22.311 This table provides type and value information for the Host2SciId0 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This identifies the SCI node ID on the second Cluster node (identified by NodeId2).

- **Host2SciId1**

Table 22.312 This table provides type and value information for the Host2SciId1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- **HostName1**

Table 22.313 This table provides type and value information for the HostName1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

Table 22.314 This table provides type and value information for the HostName1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **SharedBufferSize**
Table 22.315 This table provides type and value information for the SharedBufferSize SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the ndbd process.

- **SendLimit**

Table 22.316 This table provides type and value information for the SendLimit SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>128 - 32K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- **SendSignalId**

Table 22.317 This table provides type and value information for the SendSignalId SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**
Table 22.318 This table provides type and value information for the Checksum SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean value, and is disabled by default. When Checksum is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **OverloadLimit**

Table 22.319 This table provides type and value information for the OverloadLimit SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

#### 22.3.3.14 Configuring NDB Cluster Send Buffer Parameters

The NDB kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Table 22.320 Transporter types with maximum send buffer sizes

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>SendBufferMemory (default = 2M)</td>
</tr>
<tr>
<td>SCI</td>
<td>SendLimit (default = 8K) plus 16K</td>
</tr>
</tbody>
</table>
This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (Send Buffers overloaded in NDB kernel) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as $\text{SendBufferMemory} \times 0.8$ for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

### 22.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- **TCP/IP using 100 Mbps or gigabit Ethernet,** as discussed in Section 22.3.10, “NDB Cluster TCP/IP Connections”.

- **Direct (machine-to-machine) TCP/IP,** although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See Section 22.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”, for details.

- **Shared memory (SHM).** For more information about SHM, see Section 22.3.12, “NDB Cluster Shared-Memory Connections”.

  **Note**

  SHM is considered experimental only, and is not officially supported.

- **Scalable Coherent Interface (SCI).** For more information about SHM, see Section 22.3.13, “SCI Transport Connections in NDB Cluster”.

  **Note**

  Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available with NDB 8.0.
Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

We are working to make sure that communication with the ndbd process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

22.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (ndbd, ndbmt, ndb_mgm, and mysqld) and the management client (ndb_mgm).

Information about the program ndb_setup.py, used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that Section 22.4.26, “ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster”, contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see The NDB Cluster Auto-Installer (NDB 7.5).

For information about using mysqld as an NDB Cluster process, see Section 22.5.4, “MySQL Server Usage for NDB Cluster”.

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include ndb_restore, ndb_show_tables, and ndb_config. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

22.4.1 ndbd — The NDB Cluster Data Node Daemon

ndbd is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of ndbd processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the NDB Cluster data node program ndbd. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndbd), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.321 Command-line options for the ndbd program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address=name</td>
<td>Local bind address</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--connect-delay=#</td>
<td>Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--connect-retries=#</td>
<td>Set the number of times to retry a connection before giving up;</td>
<td>All NDB 8.0 releases</td>
</tr>

<td>Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--daemon, -d</td>
<td>Start ndbd as daemon (default); override with --nodaemon</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--foreground</td>
<td>Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--initial</td>
<td>Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--initial-start</td>
<td>Perform partial initial start (requires --nowait-nodes)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--install[=name]</td>
<td>Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--logbuffer-size=#</td>
<td>Control size of log buffer. For use when debugging with many log messages being generated; default is sufficient for normal operations.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nostart, -n</td>
<td>Don’t start ndbd immediately; ndbd waits for command to start from ndb_mgmd</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Do not start ndbd as daemon; provided for testing purposes</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires --ndb-nodeid to be used.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--remove[=name]</td>
<td>Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Causes the data log to write extra debugging information to the node log.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>
**ndbd — The NDB Cluster Data Node Daemon**

---

**Note**

All of these options also apply to the multithreaded version of this program (**ndbmtd**) and you may substitute “**ndbmtd**” for “**ndbd**” wherever the latter occurs in this section.

- **--bind-address**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--bind-address=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Causes **ndbd** to bind to a specific network interface (host name or IP address). This option has no default value.

- **--connect-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-delay=#</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3600</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the **--connect-retries** option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use **--connect-retry-delay** instead.

- **--connect-retries=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retries=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the **--connect-retry-delay** option.

- **--connect-retry-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retry-delay=#</td>
</tr>
</tbody>
</table>
ndbd — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the --connect-retries option). The default is 5 seconds.

This option takes the place of the --connect-delay option, which is now deprecated and subject to removal in a future release of NDB Cluster.

• --daemon, -d

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--daemon</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs ndbd or ndbmtd to execute as a daemon process. This is the default behavior. --nodaemon can be used to prevent the process from running as a daemon.

This option has no effect when running ndbd or ndbmtd on Windows platforms.

• --foreground

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--foreground</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes ndbd or ndbmtd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon option.

This option has no effect when running ndbd or ndbmtd on Windows platforms.

• --initial

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--initial</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An --initial start is to be used only when starting the ndbd process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:
• When performing a software upgrade which has changed the contents of any files.
• When restarting the node with a new version of ndbd.
• As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Warning

To avoid the possibility of eventual data loss, it is recommended that you not use the \texttt{--initial} option together with \texttt{StopOnError = 0}. Instead, set \texttt{StopOnError} to 0 in \texttt{config.ini} only after the cluster has been started, then restart the data nodes normally—that is, without the \texttt{--initial} option. See the description of the \texttt{StopOnError} parameter for a detailed explanation of this issue. (Bug \#24945638)

Use of this option prevents the \texttt{StartPartialTimeout} and \texttt{StartPartitionedTimeout} configuration parameters from having any effect.

Important

This option does not affect either of the following types of files:
• Backup files that have already been created by the affected node
• NDB Cluster Disk Data files (see Section \ref{sec:ndb-cluster-disk-data-tables}, “NDB Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is not necessary to do so.

• \texttt{--initial-start}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--initial-start}</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as \texttt{--nowait-nodes}.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```shell
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```
When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

---

**Important**

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

**--install[=name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--install[=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndbd</code></td>
</tr>
</tbody>
</table>

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

**--logbuffer-size=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--logbuffer-size=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2048</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

**--nodaemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nodaemon</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
**ndbd** — The NDB Cluster Data Node Daemon

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Prevents *ndbd* or *ndbmtd* from executing as a daemon process. This option overrides the **--daemon** option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for *ndbd* and *ndbmtd* on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- **--nostart, -n**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--nostart</strong></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs *ndbd* not to start automatically. When this option is used, *ndbd* connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper **START** command in the management client (see Section 22.5.2, "Commands in the NDB Cluster Management Client").

- **--nowait-nodes=\text{node\_id\_1[, node\_id\_2[, ...]]}**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--nowait-nodes=list</strong></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each *ndbd* process with **--nowait-nodes=3,5**. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait **StartPartitionedTimeout** milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one *ndbd* (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with **--nowait-nodes=3**. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- **--remove[=name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--remove[=name]</strong></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndbd</td>
</tr>
</tbody>
</table>
ndbd — The NDB Cluster Data Node Daemon

Causes an ndbd process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to ndbd.

The --remove option has no effect on non-Windows platforms.

- --verbose, -v

Causes extra debug output to be written to the node log.

You can also use NODELOG_DEBUG_ON and NODELOG_DEBUG_OFF to enable and disable this extra logging while the data node is running.

ndbd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file.

These log files are listed below. node_id is and represents the node's unique identifier. For example, ndb_2_error.log is the error log generated by the data node whose node ID is 2.

- ndb_node_id_error.log is a file containing records of all crashes which the referenced ndbd process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible ndbd exit codes and messages generated when a data node process shuts down prematurely can be found in Data Node Error Messages.

---

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_node_id_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- ndb_node_id_trace.log.trace_id is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. trace_id is a number which is incremented for each successive trace file.

- ndb_node_id_trace.log.next is the file that keeps track of the next trace file number to be assigned.

- ndb_node_id_out.log is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.
nbdinfo_select_all — Select From ndbinfo Tables

nbdinfo_select_all is a client program that selects all rows and columns from one or more tables in the ndbinfo database.

Not all ndbinfo tables available in the mysql client can be read by this program. In addition, nbdinfo_select_all can show information about some tables internal to ndbinfo which cannot be accessed using SQL, including the tables and columns metadata tables.

To select from one or more ndbinfo tables using nbdinfo_select_all, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> nbdinfo_select_all table_name1 [table_name2] [...]
```

For example:
The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbinfo_select_all`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.322 Command-line options for the `ndbinfo_select_all` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--delay=#</code></td>
<td>Set the delay in seconds between loops. Default is 5.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--loops=</code>, <code>-l</code></td>
<td>Set the number of times to perform the select. Default is 1.</td>
<td>All NDB 8.0 releases</td>
</tr>

<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>
This option sets the number of seconds to wait between executing loops. Has no effect if \textit{--loops} is set to 0 or 1.

\begin{itemize}
\item \textit{--loops=number, \texttt{-l number}}
\end{itemize}

This option sets the number of times to execute the select. Use \textit{--delay} to set the time between loops.

\subsection*{22.4.3 \texttt{ndbmtd} — The NDB Cluster Data Node Daemon (Multi-Threaded)}

\texttt{ndbmtd} is a multithreaded version of \texttt{ndbd}, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. \texttt{ndbmtd} is intended for use on host computers having multiple CPU cores. Except where otherwise noted, \texttt{ndbmtd} functions in the same way as \texttt{ndbd}; therefore, in this section, we concentrate on the ways in which \texttt{ndbmtd} differs from \texttt{ndbd}, and you should consult Section 22.4.1, \textit{``ndbd — The NDB Cluster Data Node Daemon''}, for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with \texttt{ndbd} also apply to \texttt{ndbmtd}. For more information about these options and parameters, see Section 22.4.1, \textit{``ndbd — The NDB Cluster Data Node Daemon''}, and Section 22.3.3.6, \textit{``Defining NDB Cluster Data Nodes''}, respectively.

\texttt{ndbmtd} is also file system-compatible with \texttt{ndbd}. In other words, a data node running \texttt{ndbd} can be stopped, the binary replaced with \texttt{ndbmtd}, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an appropriate value before restarting the node if you wish for \texttt{ndbmtd} to run in multithreaded fashion.) Similarly, an \texttt{ndbmtd} binary can be replaced with \texttt{ndbd} simply by stopping the node and then starting \texttt{ndbd} in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using \textit{--initial}.

Using \texttt{ndbmtd} differs from using \texttt{ndbd} in two key respects:

1. Because \texttt{ndbmtd} runs by default in single-threaded mode (that is, it behaves like \texttt{ndbd}), you must configure it to use multiple threads. This can be done by setting an appropriate value in the \texttt{config.ini} file for the MaxNoOfExecutionThreads configuration parameter or the ThreadConfig configuration parameter. Using MaxNoOfExecutionThreads is simpler, but ThreadConfig offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in \texttt{ndbmtd} processes in a somewhat different fashion from how these are generated by \texttt{ndbd} failures. These differences are discussed in more detail in the next few paragraphs.

Like \texttt{ndbd}, \texttt{ndbmtd} generates a set of log files which are placed in the directory specified by \texttt{DataDir} in the \texttt{config.ini} configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by \texttt{ndbd}.
In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error occurrence. These files, which can be found in the data node’s `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_thread_id,
```

In this pattern, `node_id` stands for the data node’s unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmtd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node’s data directory. If it is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtd`. See Data Node Error Messages, for a listing of these.

### 22.4.4 ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster’s status.

The following table includes options that are specific to the NDB Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgmd`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 22.323 Command-line options for the ndb_mgmd program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address=host</td>
<td>Local bind address</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--config-cache[=TRUE</td>
<td>FALSE]</td>
<td>Enable the management server configuration cache; TRUE by default.</td>
</tr>
<tr>
<td>--config-file=file (&gt;=), -f (&gt;=)</td>
<td>Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initial to override configuration cache if present</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--configdir=directory, --config-dir=directory (&gt;=7.0.8)</td>
<td>Specify the cluster management server’s configuration cache directory</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--daemon</td>
<td>Run ndb_mgmd in daemon mode (default)</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

**Note**

It is possible to use `ndbd` and `ndbmtd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.
<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td>Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--initial</td>
<td>Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--interactive</td>
<td>Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--log-name=name</td>
<td>A name to use when writing messages applying to this node in the cluster log.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--mycnf</td>
<td>Read cluster configuration data from the my.cnf file</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--no-nodeid-checks</td>
<td>Do not provide any node id checks</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Do not run ndb_mgmd as a daemon</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--print-full-config, -P</td>
<td>Print full configuration and exit</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--reload</td>
<td>Causes the management server to compare the configuration file with its configuration cache</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--remove [=name]</td>
<td>Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Write additional information to the log.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

- **--bind-address=host**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--bind-address=host</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
**ndb_mgmd — The NDB Cluster Management Server Daemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- **--config-cache**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--config-cache [=TRUE</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see Section 22.3.3, “NDB Cluster Configuration Files”). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- **--config-cache=0**
- **--config-cache=FALSE**
- **--config-cache=OFF**
- **--skip-config-cache**

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, OFF, or FALSE).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin_seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.
ndb_mgmd — The NDB Cluster Management Server Daemon

ndb_mgmd does not check for the configuration directory (--configdir) or attempts to create one when --skip-config-cache is used. (Bug #13428853)

- **--config-file=filename, -f filename**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--config-file=file</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the ndb_mgmd executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because ndb_mgmd was started with the --reload or --initial option, or because the management server could not find any configuration cache. This option is also read if ndb_mgmd was started with --config-cache=OFF. See Section 22.3.3, “NDB Cluster Configuration Files”, for more information.

- **--configdir=dir_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--configdir=directory</code></td>
</tr>
<tr>
<td></td>
<td><code>--config-dir=directory</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>$INSTALLDIR/mysql-cluster</td>
</tr>
</tbody>
</table>

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- **--daemon, -d**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--daemon</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs ndb_mgmd to start as a daemon process. This is the default behavior.

This option has no effect when running ndb_mgmd on Windows platforms.

- **--initial**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--initial</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data; `ndb_mgmd` ignores `--initial` unless it is the only management server running. This behavior also has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--install[=name]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--install[=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndb_mgmd</code></td>
</tr>
</tbody>
</table>

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--interactive`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--interactive</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- **--log-name=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-name=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>MgmtSrvr</code></td>
</tr>
</tbody>
</table>

Provides a name to be used for this node in the cluster log.

- **--mycnf**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mycnf</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code></td>
</tr>
</tbody>
</table>

Read configuration data from the `my.cnf` file.

- **--no-nodeid-checks**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-nodeid-checks</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code></td>
</tr>
</tbody>
</table>

Do not perform any checks of node IDs.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nodaemon</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code></td>
</tr>
</tbody>
</table>

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- **--nowait-nodes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nowait-nodes=list</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3759</td>
</tr>
</tbody>
</table>
When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other ndb_mgmd is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other ndb_mgmd to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a config.ini file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[nbdb]
NodeId = 1
HostName = 198.51.100.101

[nbdb]
NodeId = 2
HostName = 198.51.100.102

[nbdb]
NodeId = 3
HostName = 198.51.100.103

[nbdb]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using --nowait-nodes, you must also use the --ndb-nodeid option to specify the node ID of this ndb_mgmd process.
You can then start each of the cluster’s data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

---

**Note**

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-full-config, -P`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--print-full-config</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--reload</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store...
against the cluster configuration file and to reload the configuration if it finds that the configuration file
does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be
deleted. Second, `--initial` forces the management server to re-read the global configuration file and
construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When a management server starts, it checks for another management server in the same NDB Cluster and
tries to use the other management server's configuration data; `ndb_mgmd` ignores `--reload` unless it is the only management server running. This behavior also has implications when performing a rolling
restart of an NDB Cluster with multiple management nodes. See Section 22.5.5, “Performing a Rolling
Restart of an NDB Cluster”, for more information.

- **--remove [=name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--remove [=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndb_mgmd</code></td>
</tr>
</tbody>
</table>

Remove a management server process that has been installed as a Windows service, optionally
specifying the name of the service to be removed. Applies only to Windows platforms.

- **--verbose, -v**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--verbose</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Remove a management server process that has been installed as a Windows service, optionally
specifying the name of the service to be removed. Applies only to Windows platforms.

It is not strictly necessary to specify a connection string when starting the management server. However, if
you are using more than one management server, a connection string should be provided and each node in
the cluster should specify its node ID explicitly.

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for information about using connection strings.
Section 22.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", describes other options for
`ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the
DataDir as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique
node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and
  read by the management server. Section 22.3, “Configuration of NDB Cluster”, discusses how to set up
  this file.
• `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 22.5, “Management of NDB Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

• `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.

• `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

22.4.5 `ndb_mgm` — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgm`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.324 Command-line options for the `ndb_mgm` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--try-reconnect=#</code></td>
<td>Set the number of times to retry a connection before giving up; synonym for <code>--connect-retries</code></td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Execute command and exit</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--execute=name</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--connect-retries=</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• `--connect-retries=`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect-retries=</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
</tbody>
</table>
This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

The default for this option differs from its default when used with other NDB programs. See Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information.

- `--execute=command, -e command`

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.2.5, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--try-reconnect=number`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

The default for this option differs from its default when used with other NDB programs. See Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information.

- `--execute=command, -e command`

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.2.5, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--try-reconnect=number`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

Additional information about using `ndb_mgm` can be found in Section 22.5.2, “Commands in the NDB Cluster Management Client”.

### 22.4.6 `ndb_blob_tool` — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table’s BLOB and TEXT columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool's progress.

The following table includes options that are specific to `ndb_blob_tool`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_blob_tool`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

#### Table 22.325 Command-line options for the `ndb_blob_tool` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--check-orphans</code></td>
<td>Check for orphan blob parts</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--database=db_name,</code></td>
<td>Database to find the table in.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>-d</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--delete-orphans</code></td>
<td>Delete orphan blob parts</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--dump-file=file</code></td>
<td>Write orphan keys to specified file</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--verbose,</code></td>
<td>Verbose output</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>-v</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• <code>--check-orphans</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--check-orphans</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Check for orphaned BLOB parts in NDB Cluster tables.

- `--database=db_name, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--database=db_name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Specify the database to find the table in.

- `--delete-orphans`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--delete-orphans</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Remove orphaned BLOB parts from NDB Cluster tables.

- `--dump-file=file`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dump-file=file</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--verbose`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Provide extra information in the tool's output regarding its progress.

**Example**

First we create an NDB table in the test database, using the `CREATE TABLE` statement shown here:
USE test;

CREATE TABLE btest (
    c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c1 TEXT,
    c2 BLOB
) ENGINE=NDB;

Then we insert a few rows into this table, using a series of statements similar to this one:

INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));

When run with --check-orphans against this table, ndb_blob_tool generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
total parts: 10
orphan parts: 0
disconnected
NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no NDB BLOB column parts associated with column c1, even though c1 is a TEXT column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 11.8, “Data Type Storage Requirements”, for more information.

22.4.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the --config-file or --mycnf option. It is also possible to use a data node as the source by specifying its node ID with --config_from_node=node_id.

ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo and --xml options later in this section).

You can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes, --system, or --connections.
The following table includes options that are specific to ndb_config. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_config), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.326 Command-line options for the ndb_config program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--config-file=file_name</td>
<td>Set the path to config.ini file</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--config_from_node=#</td>
<td>Obtain configuration data from the node having this ID (must be a data node).</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--configinfo</td>
<td>Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with --xml to obtain XML output.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--connections</td>
<td>Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with --system or --nodes.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--diff-default</td>
<td>Print only configuration parameters that have non-default values</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--fields=string, -f</td>
<td>Field separator</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--host=name</td>
<td>Specify host</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--mycnf</td>
<td>Read configuration data from my.cnf file</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nodeid, --id</td>
<td>Get configuration of node with this ID</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--nodes</td>
<td>Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>-c</td>
<td>Short form for --ndb-connectstring</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--query=string, -q</td>
<td>One or more query options (attributes)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--query-all, -a</td>
<td>Dumps all parameters and values to a single comma-delimited string.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--rows=string, -r</td>
<td>Row separator</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>
### Format

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--system</code></td>
<td>Print SYSTEM section information only (see <code>ndb_config --configinfo</code> output). Cannot be used with <code>--nodes</code> or <code>--connections</code>.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--type=name</code></td>
<td>Specify node type</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--configinfo --xml</code></td>
<td>Use <code>--xml</code> with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```shell
shell> ndb_config --configinfo

****** SYSTEM ******

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
```
Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--config-file=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server’s configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config-from-node=##`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--config-from-node=##</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster’s configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connections`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connections</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[sci]`, `[sci default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, Section 22.3.3.13, “SCI Transport Connections in NDB Cluster”, and Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--diff-default`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--diff-default</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Print only configuration parameters that have non-default values.

- **--fields=delimiter,** \(-f \) delimiter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields=string</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a *delimiter* string used to separate the fields in the result. The default is , (the comma character).

**Note**

If the *delimiter* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- **--host=hostname**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--host=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname *localhost* usually resolves to the IP address 127.0.0.1, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when *localhost* is used in config.ini, for ndb_config --host=localhost to fail if ndb_config is run on a different host where localhost resolves to a different address (for example, on some versions of SUSE Linux, this is 127.0.0.2). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle localhost in the same fashion.

- **--mycnf**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--mycnf</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the *my.cnf* file.

- **--ndb-connectstring=connection_string,** \(-c \) connection_string

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-connectstring=connectstring</td>
</tr>
</tbody>
</table>
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connect-string=connectstring</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 22.3.3.3, “NDB Cluster Connection Strings”, and defaults to localhost:1186.

- **--nodeid=node_id, --id=node_id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-nodeid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Specify the node ID of the node for which configuration information is to be obtained. **--nodeid** is the preferred form.

- **--nodes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells ndb_config to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”).

This option is mutually exclusive with **--connections** and **--system**; only one of these 3 options can be used.

- **--query=query-options, -q query-options**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query=string</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

This is a comma-delimited list of query options—that is, a list of one or more node attributes to be returned. These include id (node ID), type (node type—that is, ndbd, mysqld, or ndb_mgmd), and any configuration parameters whose values are to be obtained.

For example, **--query=nodeid,type,indexmemory,datamemory** returns the node ID, node type, DataMemory, and IndexMemory for each node.
Note

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- **--query-all, -a**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query-all</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string.

This option was introduced in NDB 7.5.7 (Bug #60095, Bug #11766869).

- **--rows=separator, -r separator**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rows=string</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the separator contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- **--system**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--system</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells *ndb_config* to print SYSTEM information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with ****** SYSTEM ******) in the output of *ndb_config --configinfo*.

This option is mutually exclusive with **--nodes** and **--connections**; only one of these 3 options can be used.

- **--type=node_type**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--type=name</td>
</tr>
</tbody>
</table>
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ndbd</td>
</tr>
<tr>
<td></td>
<td>mysql</td>
</tr>
<tr>
<td></td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Filters results so that only configuration values applying to nodes of the specified `node_type` (ndbd, mysql, or ndb_mgmd) are returned.

- `--usage`, `--help`, or `-?

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--help</td>
</tr>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--version</td>
</tr>
</tbody>
</table>

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--configinfo --xml</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Causes `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```shell
shell> ndb_config --configinfo --xml
<configvariables protocolversion="1" ndbversionstring="5.7.25-ndb-7.5.13"
    ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
    ndbversionbuild="0">
    <section name="SYSTEM">
        <param name="Name" comment="Name of system (NDB Cluster)" type="string"
            mandatory="true"/>
        <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
            type="unsigned" default="0" min="0" max="4294967039"/>
        <param name="ConfigGenerationNumber" comment="Configuration generation number"
            type="unsigned" default="0" min="0" max="4294967039"/>
    </section>
    <section name="MYSQLD" primarykeys="NodeId">
        <param name="wan" comment="Use WAN TCP setting as default" type="bool"
            default="false"/>
        <param name="HostName" comment="Name of computer for this node"
```
ndb_config — Extract NDB Cluster Configuration Information

```xml
<param name="NodeId" comment="NodeId" type="unsigned" mandatory="true" min="1" max="255" deprecated="true"/>
<param name="ExecuteOnComputer" comment="HostName" type="string" deprecated="true"/>
```

**Note**

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (system or node) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the Diskless parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```xml
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false" restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is node (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is system (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```xml
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed" type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```xml
<param name="NodeId" type="string" default=""/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

**Examples**

1. To obtain the node ID and type of each node in the cluster:

```shell
./ndb_config --query=id,type --fields=':' --rows='
```

In this example, we used the `--fields` option to separate the ID and type of each node with a colon character (`:`), and the `--rows` option to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```shell
./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \  --query=hostname,portnumber --fields= --rows=, --type=ndb_mgmd
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node’s ID and host name, as well as the values set for its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```shell
./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' ' -r '
```
In this example, we used the short options -f and -r for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the --host option:

```
shell> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form -q to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the --nodeid option.

### 22.4.8 ndb_delete_all — Delete All Rows from an NDB Table

**ndb_delete_all** deletes all rows from the given NDB table. In some cases, this can be much faster than DELETE or even TRUNCATE TABLE.

#### Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_delete_all`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

#### Table 22.327 Command-line options for the ndb_delete_all program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname,</td>
<td>Name of the database in which the table is found</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>-d</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--transactional,</td>
<td>Perform the delete in a single transaction (may run out of operations)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>-t</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--tupscan</td>
<td>Run tup scan</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--diskscan</td>
<td>Run disk scan</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

- --transactional,-t

Use of this option causes the delete operation to be performed as a single transaction.

#### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

### 22.4.9 ndb_desc — Describe NDB Tables
ndb_desc — Describe NDB Tables

ndb_desc provides a detailed description of one or more NDB tables.

Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with ndb_desc are listed later in this section.

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (  
  id INT(11) NOT NULL AUTO_INCREMENT,  
  name VARCHAR(20) NOT NULL,  
  length_mm INT(11) NOT NULL,  
  weight_gm INT(11) NOT NULL,  
  PRIMARY KEY pk (id),  
  UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES  
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),  
  (NULL, 'shark', 3000, 1100000), (NULL, 'manta ray', 1500, 500000),  
  (NULL, 'grouper', 900, 125000), (NULL ,'puffer', 250, 2500);
```

Output from ndb_desc:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80

</tr>
</tbody>
</table>

NDBT_ProgramExit: 0 - OK

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
```

```
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY (NDB$TNODE) - UniqueHashIndex
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.
Three of the table properties that can be set using **NDB_TABLE** comments embedded in **CREATE TABLE** and **ALTER TABLE** statements are also visible in **ndb_desc** output. The table's **FRAGMENT_COUNT_TYPE** is always shown in the **FragmentCountType** column. **READ_ONLY** and **FULLY_REPLICATED**, if set to 1, are shown in the **Table options** column. You can see this after executing the following **ALTER TABLE** statement in the **mysql** client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)
```

```
shell> ./ndb_desc -c localhost fish -d test -p
  -- fish --
  Version: 4
  Fragment type: HashMapPartition
  K Value: 6
  Min load factor: 78
  Max load factor: 80
  Temporary table: no
  Number of attributes: 4
  Number of primary keys: 1
  Length of frm data: 380
  Max Rows: 0
  Row Checksum: 1
  Row GCI: 1
  SingleUserMode: 0
  ForceVarPart: 1
  PartitionCount: 1
  FragmentCount: 1
  FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
  ExtraRowGciBits: 0
  ExtraRowAuthorBits: 0
```

The warning is issued because **READ_ONLY=1** requires that the table's fragment count type is (or be set to) **ONE_PER_LDM_PER_NODE_GROUP**; **NDB** sets this automatically in such cases. You can check that the **ALTER TABLE** statement has the desired effect using **SHOW CREATE TABLE**:

```
mysql> SHOW CREATE TABLE fish\G
*************************** 1. row ***************************
  Table: fish
  Create Table: CREATE TABLE `fish` (
    `id` int(11) NOT NULL AUTO_INCREMENT,
    `name` varchar(20) NOT NULL,
    `length_mm` int(11) NOT NULL,
    `weight_gm` int(11) NOT NULL,
    PRIMARY KEY (`id`),
    UNIQUE KEY `uk` (`name`)
  ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
  COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because **FRAGMENT_COUNT_TYPE** was not set explicitly, its value is not shown in the comment text printed by **SHOW CREATE TABLE**. **ndb_desc**, however, displays the updated value for this attribute. The **Table options** column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):
For more information about these table properties, see Section 13.1.20.11, “Setting NDB_TABLE Options”.

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```sql
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”, as well as Section 13.1.16, “CREATE LOGFILE GROUP Syntax”, and Section 13.1.21, “CREATE TABLESPACE Syntax”.)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```sql
CREATE TABLE fish
  (id INT(11) NOT NULL AUTO_INCREMENT,
   name VARCHAR(20) NOT NULL,
   length_mm INT(11) NOT NULL,
   weight_gm INT(11) NOT NULL,
   PRIMARY KEY pk (id),
   -- Attributes --
   id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
   name Varchar(20)latin1_swedish_ci NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
   length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
   weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
  -- Indexes --
  PRIMARY KEY(id) - UniqueHashIndex
  PRIMARY(id) - OrderedIndex
  uk(name) - OrderedIndex
  uk$unique(name) - UniqueHashIndex
  -- Per partition info --
  Partition Row count Commit count Frag fixed memory Frag varsized memory Extent_space)
```
When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 346
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
<table>
<thead>
<tr>
<th>Partition</th>
<th>Row count</th>
<th>Commit count</th>
<th>Frag fixed memory</th>
<th>Frag varsized memory</th>
<th>Extent_space</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>2</td>
<td>32768</td>
<td>32768</td>
<td>1048576</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>4</td>
<td>32768</td>
<td>32768</td>
<td>1048576</td>
</tr>
</tbody>
</table>
NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. Beginning with NDB 7.5.4, you can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.
ndb_desc — Describe NDB Tables

The following table includes options that are specific to ndb_desc. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_desc), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.328 Command-line options for the ndb_desc program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--blob-info, -b</td>
<td>Include partition information for BLOB tables in output. Requires that the -p option also be used</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--database=dbname, -d</td>
<td>Name of database containing table</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--extra-node-info, -n</td>
<td>Include partition-to-data-node mappings in output. Requires that the -p option also be used</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--extra-partition-info, -p</td>
<td>Display information about partitions</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--retries=#, -r</td>
<td>Number of times to retry the connection (once per second)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--table=tbl_name, -t</td>
<td>Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--unqualified, -u</td>
<td>Use unqualified table names</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

- **--blob-info, -b**
  Include information about subordinate BLOB and TEXT columns.

  Use of this option also requires the use of the **--extra-partition-info (-p)** option.

- **--database=db_name, -d**
  Specify the database in which the table should be found.

- **--extra-node-info, -n**
  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

  Use of this option also requires the use of the **--extra-partition-info (-p)** option.

- **--extra-partition-info, -p**
  Print additional information about the table’s partitions.

- **--retries=#, -r**
ndb_drop_index — Drop Index from an NDB Table

Try to connect this many times before giving up. One connect attempt is made per second.

- --table=tbl_name, -t
  Specify the table in which to look for an index.

- --unqualified, -u
  Use unqualified table names.

In NDB 7.5.3 and later, table indexes listed in the output are ordered by ID. Previously, this was not deterministic and could vary between platforms. (Bug #81763, Bug #23547742)

22.4.10 ndb_drop_index — Drop Index from an NDB Table

ndb_drop_index drops the specified index from an NDB table. It is recommended that you use this utility only as an example for writing NDB API applications—see the Warning later in this section for details.

Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

The following table includes options that are specific to `ndb_drop_index`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_index`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.329 Command-line options for the ndb_drop_index program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

**Warning**

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Welcome to the MySQL monitor.  Commands end with ; or \g.
```

Your MySQL connection id is 7 to server version: 5.7.25-ndb-7.5.13
To drop an NDB table, you can use the `ndb_drop_table` utility or the SQL `DROP TABLE` statement. In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 22.4.11, "ndb_drop_table — Drop an NDB Table") to drop the table.

### 22.4.11 ndb_drop_table — Drop an NDB Table

**ndb_drop_table** drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

#### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_table`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

### 22.4.12 ndb_error_reporter — NDB Error-Reporting Utility

**ndb_error_reporter** creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.

The following table includes command options specific to the NDB Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_error_reporter`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".
Table 22.331 Command-line options for the ndb_error_reporter program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connection-timeout=timeout</td>
<td>Number of seconds to wait when connecting to nodes before timing out.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--dry-scp</td>
<td>Disable scp with remote hosts; used only for testing.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--fs</td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--skip-nodegroup=nodegroup_id</td>
<td>Skip all nodes in the node group having this ID.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- **--connection-timeout=timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connection-timeout=timeout</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Wait this many seconds when trying to connect to nodes before timing out.

- **--dry-scp**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--dry-scp</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- **--fs**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fs</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

- `--skip-nodegroup=nodegroup_id`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Skip all nodes belong to the node group having the supplied node group ID.

## 22.4.13 ndb_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

### Usage

```
ndb_import db_name file_name options
```

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this section. `ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused [api] slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing InnoDB table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

   ```sql
   mysql> USE myinnodb;
   mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
   >     > FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\'
   >     > LINES TERMINATED BY '\n'
   >     > FROM myinnodbtable;
   ```
Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```
# if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir

shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"' \
--fields-terminated-by='"' --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
shell>
```

The following table includes options that are specific to `ndb_import`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_import`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.332 Command-line options for the `ndb_import` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--abort-on-error</td>
<td>Dump core on any fatal error; used for debugging</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--ai-increment=##</td>
<td>For table with hidden PK, specify autoincrement increment. See mysqld</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--ai-offset=##</td>
<td>For table with hidden PK, specify autoincrement offset. See mysqld</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--ai-prefetch-sz=##</td>
<td>For table with hidden PK, specify number of autoincrement values that are prefetched. See mysqld</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--connections=#</td>
<td>Number of cluster connections to create</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--continue</td>
<td>When job fails, continue to next job</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--db-workers=#</td>
<td>Number of threads, per data node, executing database operations</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td><code>--errins-type=name</code></td>
<td>Error insert type, for testing purposes; use “list” to obtain all possible values</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--errins-delay=#</code></td>
<td>Error insert delay in milliseconds; random variation is added</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--fields-enclosed-by=char</code></td>
<td>Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--fields-escaped-by=name</code></td>
<td>Same as FIELDS ESCAPED BY option for LOAD DATA statements</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--fields-optionally-enclosed-by=char</code></td>
<td>Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--fields-terminated-by=char</code></td>
<td>Same as FIELDS TERMINATED BY option for LOAD DATA statements.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--idlesleep=#</code></td>
<td>Number of milliseconds to sleep waiting for more to do</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--idlespin=#</code></td>
<td>Number of times to re-try before idlesleep</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--ignore-lines=#</code></td>
<td>Ignore first # lines in input file. Used to skip a non-data header.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--input-type=name</code></td>
<td>Input type: random or csv</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--input-workers=#</code></td>
<td>Number of threads processing input. Must be 2 or more if --input-type is csv</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--keep-state</code></td>
<td>Preserve state files</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--lines-terminated-by=name</code></td>
<td>Same as LINES TERMINATED BY option for LOAD DATA statements</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--log-level=#</code></td>
<td>Set internal logging level; for debugging and development</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--max-rows=#</code></td>
<td>Import only this number of input data rows; default is 0, which imports all rows</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--monitor=#</code></td>
<td>Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some predefined limit.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>
## ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--no-asynch</td>
<td>Run database operations as batches, in single transactions</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--no-hint</td>
<td>Do not use distribution key hint to select data node (TC)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--opbatch=#</td>
<td>A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of asynch transactions. Value 0 is not valid</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--opbytes=#</td>
<td>Limit bytes in execution batch (default 0 = no limit)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--output-type=name</td>
<td>Output type: ndb is default, null used for testing</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--output-workers=#</td>
<td>Number of threads processing output or relaying database operations</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--pagesize=#</td>
<td>Align I/O buffers to given size</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--pagecnt=#</td>
<td>Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--polltimeout=#</td>
<td>Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--rejects=#</td>
<td>Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--resume</td>
<td>If job aborted (temporary error, user interrupt), resume with rows not yet processed</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--rowbatch=#</td>
<td>Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--rowbytes=#</td>
<td>Limit bytes in row queues (0 = no limit)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--state-dir=name</td>
<td>Where to write state files; current directory is default</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--stats</td>
<td>Save performance and statistics information in *.sto and *.stt files</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>
### Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--tempdelay=#</td>
<td>Number of milliseconds to sleep between temporary errors</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--temppers errors=#</td>
<td>Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--verbose=#, -v</td>
<td>Enable verbose output</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

- **--abort-on-error**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--abort-on-error</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Dump core on any fatal error; used for debugging only.

- **--ai-increment=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ai-increment=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with a hidden primary key, specify the autoincrement increment, like the the `auto_increment_increment` system variable does in the MySQL Server.

- **--ai-offset=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ai-offset=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- **--ai-prefetch-sz=#**
**ndb_import — Import CSV Data Into NDB**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--ai-prefetch-sz=#</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1024</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- **--connections=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--connections=#</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of cluster connections to create.

- **--continue**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--continue</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>FALSE</td>
</tr>
</tbody>
</table>

When a job fails, continue to the next job.

- **--db-workers=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--db-workers=#</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>4</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of threads, per data node, executing database operations.

- **--errins-type=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--errins-type=name</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Enumeration</td>
</tr>
</tbody>
</table>
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>stopjob, stopall, sighup, sigint, list</td>
</tr>
</tbody>
</table>

Error insert type; use list as the name value to obtain all possible values. This option is used for testing purposes only.

- `--errins-delay=##` 

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--errins-delay=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- `--fields-enclosed-by=char` 

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-enclosed-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

This works in the same way as the FIELDS ENCLOSED BY option does for the LOAD DATA statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- `--fields-escaped-by=name` 

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-escaped-by=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\</td>
</tr>
</tbody>
</table>

Specify an escape character in the same way as the FIELDS ESCAPED BY option does for the SQL LOAD DATA statement.

- `--fields-optionally-enclosed-by=char`
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-optionally-enclosed-by=char</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- `--fields-terminated-by=char`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-terminated-by=char</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\t</td>
</tr>
</tbody>
</table>

This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- `--idlesleep=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--idlesleep=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of milliseconds to sleep waiting for more work to perform.

- `--idlespin=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--idlespin=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of times to retry before sleeping.

- `--ignore-lines=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ignore-lines=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

3794
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Cause ndb_import to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- **--input-type**=`name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--input-type=name</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>csv</td>
</tr>
<tr>
<td>Valid Values</td>
<td>random, csv</td>
</tr>
</tbody>
</table>

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only.

- **--input-workers**=`#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--input-workers=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing input.

- **--keep-state**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--keep-state</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

By default, ndb_import removes all state files (except non-empty *.rej files) when it completes a job. Specify this option (no argument is required) to force the program to retain all state files instead.

- **--lines-terminated-by**=`name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lines-terminated-by=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n</td>
</tr>
</tbody>
</table>
This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

- **--log-level=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-level=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- **--max-rows=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--max-rows=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Import only this number of input data rows; the default is 0, which imports all rows.

- **--monitor=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--monitor=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- **--no-asynch**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--no-asynch</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Run database operations as batches, in single transactions.

- `--no-hint`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-hint</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Do not use distribution key hinting to select a data node.

- `--opbatch=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--opbatch=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- `--opbytes=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--opbytes=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- `--output-type=name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--output-type=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb</td>
</tr>
<tr>
<td>Valid Values</td>
<td>null</td>
</tr>
</tbody>
</table>

Set the output type. `ndb` is the default. `null` is used only for testing.

- `--output-workers=#`
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--output-workers=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing output or relaying database operations.

- `--pagesize=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--pagesize=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Align I/O buffers to the given size.

- `--pagecnt=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--pagecnt=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- `--polltimeout=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--polltimeout=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- `--rejects=#`
**--rejects=*/#

**Property** | **Value**
---|---
Command-Line Format | `--rejects=##`
Type | Integer
Default Value | 0
Minimum Value | 0
Maximum Value | 4294967295

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the `.rej` file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using `--resume` is considered a "new" run for this purpose.

- **--resume**

**Property** | **Value**
---|---
Command-Line Format | `--resume`
Type | Boolean
Default Value | FALSE

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- **--rowbatch=*/#

**Property** | **Value**
---|---
Command-Line Format | `--rowbatch=##`
Type | Integer
Default Value | 0
Minimum Value | 0
Maximum Value | 4294967295

Set a limit on the number of rows per row queue. Use 0 for no limit.

- **--rowbytes=*/#

**Property** | **Value**
---|---
Command-Line Format | `--rowbytes=##`
Type | Integer
Default Value | 262144
Minimum Value | 0
Maximum Value | 4294967295

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- **--stats**
**ndb_import — Import CSV Data Into NDB**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--stats</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Save information about options related to performance and other internal statistics in files named *.sto and *.stt. These files are always kept on successful completion (even if --keep-state is not also specified).

- **--state-dir=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--state-dir=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>.</td>
</tr>
</tbody>
</table>

Where to write the state files (tbl_name.map, tbl_name.rej, tbl_name.res, and tbl_name.stt) produced by a run of the program; the default is the current directory.

- **--tempdelay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--tempdelay=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of milliseconds to sleep between temporary errors.

- **--temperrors=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--temperrors=#</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the .rej file.

- **--verbose, -v**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
</tbody>
</table>
**ndb_index_stat — NDB Index Statistics Utility**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>false</code></td>
</tr>
</tbody>
</table>

Enable verbose output.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

`ndb_import` was added in NDB 7.6.2.

### 22.4.14 ndb_index_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

**Usage**

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database (-d)` option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
```

table:City index:PRIMARY fragCount:2
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000
NDBT_ProgramExit: 0 - OK

**sampleVersion** is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes sampleVersion to be incremented.

**loadTime** shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

**sampleCount** is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

**sampleCount** can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

**keyBytes** is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).
**totalBytes** is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The **--verbose** option provides some additional output, as shown here:

```shell
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected
NDBT_ProgramExit: 0 - OK
shell>
```

If the only output from the program is **NDBT_ProgramExit: 0 - OK**, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the **--update** option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

### Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including `ndb_index_stat`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=name,</td>
<td>Name of the database containing the table.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>-d</td>
<td>Delete index statistics for the given table, stopping any auto-update</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--delete</td>
<td>previously configured.</td>
<td></td>
</tr>
<tr>
<td>--update</td>
<td>Update index statistics for the given table, restarting any auto-update</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td></td>
<td>previously configured.</td>
<td></td>
</tr>
<tr>
<td>--dump</td>
<td>Print the query cache.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--query=##</td>
<td>Perform a number of random range queries on first key attr (must be int unsigned).</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--sys-drop</td>
<td>Drop any statistics tables and events in NDB kernel (all statistics are lost)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--sys-create</td>
<td>Create all statistics tables and events in NDB kernel, if none of them already exist</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>
### ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--sys-create-if-not-exist</code></td>
<td>Create any statistics tables and events in NDB kernel that do not already exist.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--sys-create-if-not-valid</code></td>
<td>Create any statistics tables or events that do not already exist in the NDB kernel. after dropping any that are invalid.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--sys-check</code></td>
<td>Verify that NDB system index statistics and event tables exist.</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>

<tr>
<td><code>--loops=#</code></td>
<td>Set the number of times to perform a given command. Default is 0.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

#### ndb_index_stat statistics options.

The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see `ndb_index_stat system options`).

- `--database=name, -d name`  

```plaintext
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--database=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>
```

The name of the database that contains the table being queried.

- `--delete`  

```plaintext
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--delete</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>false</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>
```

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--update`
**ndb_index_stat** — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--update</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- **--dump**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dump</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Dump the contents of the query cache.

- **--query=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Perform random range queries on first key attribute (must be int unsigned).

**ndb_index_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see **ndb_index_stat statistics options**).

- **--sys-drop**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-drop</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*
• **--sys-create**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-create</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

• **sys-create-if-not-exist**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-create-if-not-exist</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

• **--sys-create-if-not-valid**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-create-if-not-valid</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

• **--sys-check**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-check</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Verify that all required system statistics tables and events exist in the NDB kernel.

• **--sys-skip-tables**
ndb_move_data — NDB Data Copy Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-skip-tables</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Do not apply any --sys-* options to any statistics tables.

- **--sys-skip-events**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-skip-events</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Do not apply any --sys-* options to any events.

- **--verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Turn on verbose output.

- **--loops=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--loops=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Repeat commands this number of times (for use in testing).

22.4.15 ndb_move_data — NDB Data Copy Utility

ndb_move_data copies data from one NDB table to another.
Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

The following table includes options that are specific to `ndb_move_data`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_move_data`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 22.334 Command-line options for the `ndb_move_data` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--abort-on-error</code></td>
<td>Dump core on permanent error (debug option)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--character-sets-dir=name</code></td>
<td>Directory where character sets are</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--database=dbname</code></td>
<td>Name of the database in which the table is found</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>Drop source table after all rows have been moved</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--drop-source</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--error-insert</code></td>
<td>Insert random temporary errors (testing option)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--exclude-missing-columns</code></td>
<td>Ignore extra columns in source or target table</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--lossy-conversions</code>, <code>-l</code></td>
<td>Allow attribute data to be truncated when converted to a smaller type</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--promote-attributes</code>, <code>-A</code></td>
<td>Allow attribute data to be converted to a larger type</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--staging-tries=x[,y[,z]]</code></td>
<td>Specify tries on temporary errors. Format is x[;y[;z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Enable verbose messages</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

- `--abort-on-error` Dump core on permanent error (debug option).

- `--character-sets-dir=name`
### ndb_move_data — NDB Data Copy Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--character-sets-dir=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Directory where character sets are.

- `--database=dbname, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--database=dbname</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database in which the table is found.

- `--drop-source`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--drop-source</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Drop source table after all rows have been moved.

- `--error-insert`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--error-insert</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--exclude-missing-columns</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Ignore extra columns in source or target table.

- `--lossy-conversions, -l`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lossy-conversions</td>
</tr>
</tbody>
</table>
## 22.4.16 ndb_perror — Obtain NDB Error Message Information

ndb_perror shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. Added to the MySQL NDB Cluster distribution in NDB 7.6.4, it is intended as a drop-in replacement for perror --ndb.

### Usage

**ndb_perror** [options] error_code

ndb_perror does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```shell
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application
```
To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
shell> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `perror`, `ndb_perror` accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for `ndb_perror` are described later in this section.

`ndb_perror` replaces `perror --ndb`, which is deprecated as of NDB 7.6.4 and subject to removal in a future release of MySQL NDB Cluster. To make substitution easier in scripts and other applications that might depend on `perror` for obtaining NDB error information, `ndb_perror` supports its own “dummy” `--ndb` option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program `ndb_perror`. Additional descriptions follow the table.

### Table 22.335 Command-line options for the `ndb_perror` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--help</code>, <code>-?</code></td>
<td>Display help text</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--ndb</code></td>
<td>For compatibility with applications depending on old versions of <code>perror</code>; does nothing</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--silent</code>, <code>-s</code></td>
<td>Show error message only</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--version</code>, <code>-v</code></td>
<td>Print program version information and exit</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td><code>--verbose</code>, <code>-v</code></td>
<td>Verbose output; disable with <code>--silent</code></td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

### Additional Options

- `--help`, `-?`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--help</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Display program help text and exit.
ndb_print_backup_file — Print NDB Backup File Contents

- **--ndb**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

For compatibility with applications depending on old versions of perror that use that program's **--ndb** option. The option when used with ndb_perror does nothing, and is ignored by it.

- **--silent, -s**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--silent</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Show error message only.

- **--version, -V**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--version</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Print program version information and exit.

- **--verbose, -v**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Verbose output; disable with **--silent**.

**22.4.17 ndb_print_backup_file — Print NDB Backup File Contents**

ndb_print_backup_file obtains diagnostic information from a cluster backup file.

**Usage**

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory BACKUP-#, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 22.5.3.1, “NDB Cluster Backup Concepts”.

3811
**ndb_print_file** — Print NDB Disk Data File Contents

Like **ndb_print_schema_file** and **ndb_print_sys_file** (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) **ndb_print_backup_file** must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

22.4.18 **ndb_print_file** — Print NDB Disk Data File Contents

**ndb_print_file** obtains information from an NDB Cluster Disk Data file.

**Usage**

```
ndb_print_file [-v] [-q] file_name+
```

*file_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like **ndb_print_schema_file** and **ndb_print_sys_file** (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) **ndb_print_file** must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

**ndb_print_file** supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).
- `--help, -h, -?`: Print help message.

For more information, see Section 22.5.13, “NDB Cluster Disk Data Tables”.

22.4.19 **ndb_print_frag_file** — Print NDB Fragment List File Contents

**ndb_print_frag_file** obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

**Usage**

```
ndb_print_frag_file file_name
```

*file_name* is the name of a cluster fragment list file, which matches the pattern **SX.FragList**, where **X** is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID **nodeid**, in directories named **ndb_nodeid_fs/DN/DBDIH/**, where **N** is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory Files.

Like **ndb_print_backup_file**, **ndb_print_sys_file**, and **ndb_print_schema_file** (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a
ndb_print_schema_file — Print NDB Schema File Contents

management server), **ndb_print_frag_file** must be run on a cluster data node, since it accesses the
data node file system directly. Because it does not make use of the management server, this utility can be
used when the management server is not running, and even when the cluster has been completely shut
down.

**Additional Options**

None.

**Sample Output**

```
shell> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
```

22.4.20 **ndb_print_schema_file** — Print NDB Schema File Contents

**ndb_print_schema_file** obtains diagnostic information from a cluster schema file.

**Usage**

```
ndb_print_schema_file file_name
```

*file_name* is the name of a cluster schema file. For more information about cluster schema files, see
**NDB Cluster Data Node File System Directory Files**.

Like **ndb_print_backup_file** and **ndb_print_sys_file** (and unlike most of the other **NDB** utilities
that are intended to be run on a management server host or to connect to a management server)
**ndb_print_schema_file** must be run on a cluster data node, since it accesses the data node file
system directly. Because it does not make use of the management server, this utility can be used when the
management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.
22.4.21 ndb_print_sys_file — Print NDB System File Contents

ndb_print_sys_file obtains diagnostic information from an NDB Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

*file_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (*DataDir*); the path under this directory to system files matches the pattern `ndb_#_fs/D#DBDIH/F#sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

22.4.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

**Note**
Prior to NDB 7.2, this utility was named `ndbd_redo_log_reader`.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the NDB Cluster program `ndb_redo_log_reader`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_redo_log_reader`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

**Table 22.336 Command-line options for the `ndb_redo_log_reader` program**

</table>

Usage

ndb_redo_log_reader  file_name [options]

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (DataDir); the path under this directory to the redo log files matches the pattern ndb_nodeid_fs/D#/DBLQH/S#.FragLog.nodeid is the data node's node ID. The two instances of # each represent a number (not necessarily the same number); the number following D is in the range 8-39 inclusive; the range of the number following S varies according to the value of the NoOfFragmentLogFiles configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory Files.

The name of the file to be read may be followed by one or more of the options listed here:

- **-dump**

<table>
<thead>
<tr>

-pageindex #: Start at this page index.

# is an integer between 12 and 8191, inclusive.

- twiddle

Bit-shifted dump.

Like ndb_print_backup_file and ndb_print_schema_file (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_redo_log_reader must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

22.4.23 ndb_restore — Restore an NDB Cluster Backup

The cluster restoration program is implemented as a separate command-line utility ndb_restore, which can normally be found in the MySQL bin directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

ndb_restore must be executed once for each of the backup files that were created by the START BACKUP command used to create the backup (see Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.
Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 22.5.8, “NDB Cluster Single User Mode”, for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_restore`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.337 Command-line options for the `ndb_restore` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--append</td>
<td>Append data to a tab-delimited file</td>

<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>--skip-unknown-objects</td>
<td>Causes schema objects not recognized by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>
### ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--tab=dir_name,</td>
<td>Creates a tab-separated .txt file for each</td>
<td>All NDB 8.0 releases</td>
</tr>
<tr>
<td>-T dir_name</td>
<td>table in the given path</td>
<td></td>
</tr>
<tr>
<td>--verbose=#</td>
<td>Level of verbosity in output</td>
<td>All NDB 8.0 releases</td>
</tr>
</tbody>
</table>

Typical options for this utility are shown here:

```sh
dbd_restore [-c connection_string] -n node_id -b backup_id \
[-m] -r --backup_path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup_path` options. In addition, when `ndb_restore` is used to restore any tables containing unique indexes, you must include `--disable-indexes` or `--rebuild-indexes` (Bug #57782, Bug #11764893)

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server (see Section 22.3.3.3, "NDB Cluster Connection Strings"). If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty [api] or [mysqld] section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

More detailed information about all options used by `ndb_restore` can be found in the following list:

- **--append**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--append</td>
</tr>
</tbody>
</table>

  When used with the `--tab` and `--print_data` options, this causes the data to be appended to any existing files having the same names.

- **--backup_path=dir_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--backup-path=dir_name</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>./</td>
</tr>
</tbody>
</table>

  The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup.
to be restored. For example, if the data node's **DataDir** is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the *ndb_restore* executable is located, and may be optionally prefixed with `backup_path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then *ndb_restore* must be run twice—once for each storage node in the cluster where the backup was taken. However, *ndb_restore* cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version.

---

**Important**

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of *ndb_restore*. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of *ndb_restore* from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.13 to a cluster running NDB Cluster 7.4.23, you must use the *ndb_restore* that comes with the NDB Cluster 7.5.13 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an [api] or [mysqld] section in the cluster `config.ini` file available for each concurrent *ndb_restore* process. However, the data files must always be applied before the logs.

- **--backupid=#,-b**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--backupid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”.)

---

**Important**

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

In NDB 8.0.15 and later, this option is required.

- **--connect,-c**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect</td>
</tr>
</tbody>
</table>
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Alias for --ndb-connectstring.

- --disable-indexes

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--disable-indexes</td>
</tr>
</tbody>
</table>

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using --rebuild-indexes, which should be faster than rebuilding indexes concurrently for very large tables.

- --dont_ignore_systab_0, -f

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dont-ignore-systab-0</td>
</tr>
</tbody>
</table>

Normally, when restoring table data and metadata, ndb_restore ignores the copy of the NDB system table that is present in the backup. --dont_ignore_systab_0 causes the system table to be restored. This option is intended for experimental and development use only, and is not recommended in a production environment.

- --exclude-databases=db-list

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--exclude-databases=db-list</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>Comma-delimited list of one or more databases which should not be restored. This option is often used in combination with --exclude-tables; see that option's description for further information and examples.</td>
</tr>
</tbody>
</table>

- --exclude-intermediate-sql-tables=[TRUE|FALSE]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--exclude-intermediate-sql-tables=[TRUE</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

When performing copying ALTER TABLE operations, mysql creates intermediate tables (whose names are prefixed with #sql-). When TRUE, the --exclude-intermediate-sql-tables option keeps ndb_restore from restoring such tables that may have been left over from these operations. This option is TRUE by default.

- --exclude-missing-columns
It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- **--exclude-missing-columns**

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- **--exclude-tables=table-list**

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

**Table 22.338** Several invocations of `ndb_restore` using `--exclude-*` options, and the effects these options have on restoring from an NDB Cluster backup.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--exclude-databases=db1</code></td>
<td>All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code>)</td>
<td>All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t1</code></td>
<td>All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code>)</td>
<td>All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored</td>
</tr>
</tbody>
</table>
You can use these two options together. For example, the following causes all tables in all databases except for databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-enclosed-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-optionally-enclosed-by</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>
The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- **--fields-terminated-by=char**

#### Property | Value
---|---
Command-Line Format | `--fields-terminated-by=char`
Type | String
Default Value | `\t` (tab)

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- **--hex**

#### Property | Value
---|---
Command-Line Format | `--hex`

If this option is used, all binary values are output in hexadecimal format.

- **--include-databases=db-list**

#### Property | Value
---|---
Command-Line Format | `--include-databases=db-list`
Type | String
Default Value |

Comma-delimited list of one or more databases to restore. Often used together with **--include-tables**; see the description of that option for further information and examples.

- **--include-tables=table-list**

#### Property | Value
---|---
Command-Line Format | `--include-tables=table-list`
Type | String
Default Value |

Comma-delimited list of tables to restore; each table reference must include the database name.

When **--include-databases** or **--include-tables** is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using **--include-*** options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:
Table 22.339 Several invocations of ndb_restore using --include-* options, and their effects on restoring from an NDB Cluster backup.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--include-databases=db1</code></td>
<td>Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code>)</td>
<td>Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t1</code></td>
<td>Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code>)</td>
<td>Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code>, <code>db2</code>, or any other database are restored</td>
</tr>
</tbody>
</table>

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

---

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lines-terminated-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>\n</code> (linebreak)</td>
</tr>
</tbody>
</table>

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--lossy-conversions, -L`

---

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lossy-conversions</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code> (If option is not used)</td>
</tr>
</tbody>
</table>
This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- **`--no-binlog`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-binlog</code></td>
</tr>
</tbody>
</table>

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- **`--no-restore-disk-objects, -d`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-restore-disk-objects</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information about these.

- **`--no-upgrade, -u`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-upgrade</code></td>
</tr>
</tbody>
</table>

When using `ndb_restore` to restore a backup, VARCHAR columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- **`--ndb-nodegroup-map=map, -z`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-nodegroup-map=map</code></td>
</tr>
</tbody>
</table>

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

- **`--nodeid=#, -n`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nodeid=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>
**ndb_restore** — Restore an NDB Cluster Backup

Specify the node ID of the data node on which the backup was taken.
